IBM Cloud Pak for AIOps 4.8.0 1

Release notes 1
- What's new 1
  - Known issues and limitations 4
  - Deprecated and removed functions 25
  - Frequently Asked Questions 27

Overview 30
- Architecture 36
  - IBM Cloud Pak for AIOps architecture 36
  - Infrastructure Automation architecture 39
- Regulatory compliance 41
  - Federal Information Processing Standards (FIPS) 41
    - Enabling FIPS support for IBM Cloud Pak for AIOps 42
    - Enabling FIPS support for Infrastructure Automation 44
    - Enabling FIPS support for a Netcool integration 45
  - Audit logging 47
    - Logged actions and data 48
    - Audit log messages 51
    - Enabling Audit for Infrastructure Automation {{site.data.keyword.infra_mgmt_manageservices}} 55
  - Security and Privacy by Design (SPbD) 56
  - GDPR readiness 56
  - Data retention 59

Getting started 60
- Roles and archetypes 60
- IBM Cloud Pak for AIOps Workflows 61

Deploying on Linux 63
- Planning 63
  - Incremental adoption ({{site.data.keyword.cp4waiops_notm}}) 67
  - Configuring local volumes 68
- Online installation 70
- Offline installation 74
- Online upgrade 79
- Offline upgrade 81
- Administering 84
  - Adding a control plane node 84
  - Adding a worker node 85
  - Backup and restore 86
  - Configuring topology resources for production 86
  - Recovering from node failure 87
  - Removing a node 89
  - Resizing storage 90
  - Restarting the environment 90
  - Updating the deployment type 95
  - Using a custom certificate 96
  - MustGather tool 96
- Uninstalling 97

Deploying on OpenShift 97
- Planning 98
  - Incremental adoption ({{site.data.keyword.cp4waiops_notm}}) 98
  - Supported platforms 99
  - Hardware requirements 101
    - Performance considerations for metrics data collection 104
    - Performance considerations for logs data collection 105
    - Performance considerations for events data collection 105
    - Performance considerations for tickets data collection 105
    - Performance considerations for observers 106
  - Storage requirements 106
  - Network requirements 111
  - High availability considerations 113
    - Multi-zone HA 113
    - Cold standby DR 115
      - Backing up IBM Cloud Pak for AIOps 116
      - Restoring IBM Cloud Pak for AIOps 118
      - Troubleshooting 122
  - Security considerations 124
    - Verifying images 125
    - Downloading or listing images 126

Licensing 127
Passport Advantage part numbers 128
Supporting products and extensions 130
Installing 130
Starter installation 131
Production installation 138
Online (console) 138
Online (CLI) 146
Offline 155
Bastion host 157
Portable device 169
Installing on cloud platforms 182
Installing on ARO 182
Installing on GCP 185
Installing on ROKS 187
Installing on ROSA 187
Installing on AWS GovCloud 191
Upgrading 193
Online (console) 194
Online (CLI) 198
Offline 203
Administering 208
Backup and restore 209
Backup and restore with OADP 209
Installing the backup and restore tools 211
Configuring ODF as backup storage for OADP 216
Backing up Cloud Pak for AIOps 219
Restoring Cloud Pak for AIOps 224
Upgrading the backup and restore artifacts 236
Backup and restore with Fusion (Cold Standby DR) 115
Backing up IBM Cloud Pak for AIOps 116
Restoring IBM Cloud Pak for AIOps 118
Troubleshooting 122
Configuring topology resources for production 245
Health checks and monitoring 246
Installation and upgrade health checks 248
Proactive health checks 249
Reactive health checks 249
Self-monitoring with alerts 250
Self-monitoring with topology 255
Monitoring with Prometheus and Grafana 261
Cloud Pak for AIOps health dashboard 269
Cloud Pak for AIOps usage dashboard 294
Monitoring data processed 313
Circuit breaker for Kafka robustness and stability 316
Creating a cluster monitoring ConfigMap object 316
Creating a user-defined workload monitoring ConfigMap 316
Configuring core OpenShift monitoring components 317
Configuring components that monitor user-defined projects 318
Creating Prometheus rule to generate OpenShift alerts 318
Push alerts generated in OpenShift into {{site.data.keyword.cp4waiops_short}} 321
Creating a policy to promote alerts to an incident 323
Managing certificates 324
Using a custom certificate 324
Multi-zone rebalancing 325
Resizing storage 328
Restarting the environment 331
Secure Tunnels 336
Installing Secure Tunnel 338
Installing the Connector 342
Upgrading Secure Tunnel 346
Creating Secure Tunnel Connections 347
Viewing Secure Tunnel 363
Modifying Secure Tunnel 364
Auditing Secure Tunnel 365
Updating the deployment type 368
Uninstalling 369
Infrastructure Automation 381

Defining integrations 381
Available integrations 381
Netcool integrations 388

IBM Tivoli Netcool/Impact integration 389
Configuring an integration in IBM Tivoli Netcool/Impact 393
IBM Tivoli Netcool/OMNIbus integrations 395
Configuring launch-in-context from IBM Tivoli Netcool/OMNIbus 400
Adding incidents and alerts to the DASH navigation menu 400
Creating tools for launch-in-context from the Event Viewer 401
Creating a TLS-enabled integration to an OpenShift ObjectServer 401
Filter clause 402
Netcool event load management 403
Netcool connector troubleshooting 404
Netcool event load splitting calculation 404
Integrations 408
Integrations UI 409
Integration types 410
Outgoing integrations 411
Microsoft Teams integration 411
Configuring Microsoft Teams application for integration 415
Slack integration 416
Configuring Slack for integration 419
ServiceNow App integration 421
Creating a Change Risk Assessment 427
ServiceNow App privacy policy 427
SSH integrations 428
Installing new SSH key during migration 430
SSH algorithms 434
Email Notification integration 434
GitHub integration 439
Ansible integrations (bi-directional) 442
IBM Db2 integration 443
Incoming integrations 444
Appdynamics integrations 445
AWS CloudWatch integrations 450
Custom integrations 454
Creating custom integrations using the integration SDK 461
Creating dashboards using the dashboard extension toolkit 461
Dynatrace integrations 461
ELK integrations 472
Generating API Key for ELK integrations 478
EFK integrations 478
Falcon LogScale integrations 483
Generic webhook integration 487
Integrating with IBM SevOne Network Performance Management 490
Integrating with IBM Turbonomic 491
Integrating with Zabbix 493
Example: IBM SevOne NMS mappings 496
Example: Prometheus AlertManager mappings 499
Infrastructure Management integrations 502
Instana integrations 504
Jira integrations 509
Kafka integrations 511
Metric Manager integrations 517
Mezmo integrations 518
New Relic integrations 523
Observer integrations 528
PagerDuty integrations 528
ServiceNow integration 531
Mapping similar ticket data from ServiceNow 539
Splunk integrations 541
Zabbix integrations 547
Delay configurations in data integrations 553
Mapping data 553
Log data 554
Event data 560
Performance considerations for metric data collection 563
Loading data for AI training 564
Loading data from domain-specific log sources 564

Example configurations 926

Cloud Pak administration 927
UI console 927
Supported browsers 927
Accessing a cluster with the console 928
Customizing the platform UI 928
Enabling and disabling tours 928
Disabling auto complete on the login page 929
Customizing the Platform UI (Zen) route 929
Updating default routes to custom hostname 930
Customizing the branding of the web client 931
Customizing the home page 932
Supported languages 933
Managing user access control 934
Identity Management (IM) 935
Multiple LDAP domains 936
Authentication types 936
Delegating authentication to OpenShift 938
OIDC registration by using client CRD 939
Auditing IM service 940
Identity Management for IBM Cloud Pak for AIOps platform users 942
Configuring single sign-on using SAML 942
Configuring single sign-on using IBM Cloud Pak for AIOps UI 943
Configuring single sign-on using OpenID Connect 945

Configuring LDAP connection 947
Custom search base support for LDAP group and user entity in SCIM group and user APIs 951
Using realName as a query filter 952
Enabling LDAP Nested Search 953
Changing LDAP cache settings 958
Changing LDAP search settings 959
Changing SCIM LDAP search limit settings 961
Adding custom SCIM attributes 962
Updating SCIM LDAP attributes mapping 965
Enhancing SCIM group and user API performance 968
SCIM pagination support for LDAP server 970
Changing LDAP contextPool settings 971
Cluster configurations 972
Allowing limited users to log in by using only LDAP 972
Updating custom hostname and TLS secret by using a configmap 975
Changing the cluster administrator access credentials 979
Customizing the cluster access URL 981
Adding a logout redirect URL 983
Configuring access and identity token validity 984
Changing the security role mappings refresh time interval that is used during authorization 985
Changing LDAP search cache variable values 986
Using a proxy server for outbound traffic 987
IM sample configuration 988
SCIM configuration by using IBM Cloud Pak for AIOps UI 988
IBM Cloud Pak SCIM OKTA integration 989
IBM Cloud Pak SCIM AZURE AD integration 996
IBM Cloud Pak JIT support for SCIM OKTA and Azure AD 1004
Integrating SAML with Azure Active Directory 1006
EDB postgresql database backup and restore 1009
Backing up EDB postgresql database 1009
Restoring EDB postgresql database 1010
Adding users 1011
Managing user groups 1013
Roles and permissions 1015
Managing profiles 1022
Creating restriction filters 1025
Creating redaction policies 1031
Managing profiles 1022
Creating restriction filters 1025
Creating redaction policies 1031
Setting your preferences 1050
Secret rotation 1051
Issue Resolution Core operator secret usage 1051
Issue Resolution Lifecycle operator secret usage 1058
Administering data storage 1059
Restricting the number of alerts returned by the data layer 1061
Disabling additional alert count queries 1062
Updating usage data collection preferences 1063
Clearing out topology data without reinstalling 1064
Setting the idle session timeout 1066
Configuring probable cause 1067

Troubleshooting

Support

IBM Cloud Pak® solutions closely align with other industry-leading software providers. While IBM values the use of inclusive language, terms that are outside of IBM's direct influence, for the sake of maintaining user understanding, are sometimes required. As other industry leaders join IBM in embracing the use of inclusive language, IBM will continue to update the documentation to reflect those changes.

Release notes

Learn more about the IBM Cloud Pak® for AIOps documentation and what's new with IBM Cloud Pak for AIOps 4.8.0:

- What's new
- Known issues and limitations
- Regulatory compliance
- Deprecated and removed functions
- Frequently Asked Questions (FAQs)

What's new in IBM Cloud Pak for AIOps 4.8.0

Get a quick overview of what is new with IBM Cloud Pak® for AIOps.

IBM Cloud Pak for AIOps leverages AI to streamline IT operations, increase uptime, improve efficiency, and reduce costs. The solution supports Operations teams to deliver optimum performance and assurance by:

- Breaking down data silos
- Providing real-time insights into IT systems
- Augmenting incident management with AI
- Automating incident resolution

With Version 4.8.0, IBM Cloud Pak for AIOps delivers improved capabilities and new features for installing, runbooks, integrating with Instana, and more.

Overall, the following new features and changes are introduced with this IBM Cloud Pak version:

- Install and upgrade
- Managing user access control
- Defining integrations
- Automating processes (Policies, Runbooks, Actions)
- Resolving incidents and alerts
- Managing applications (services) and viewing topologies
- Infrastructure Automation
- Non-production (tech preview)
- Documentation changes
- Security and compliance

Install and upgrade

- **Elasticsearch is replaced by OpenSearch (IBM Cloud Pak for AIOps on Red Hat® OpenShift®)** Note that deployments of IBM Cloud Pak for AIOps on Linux already use OpenSearch. The following updates have been made to support this transition:
  - An OpenSearch filter is added to the *ibm-pak mirror-manifests* command in the offline installation and upgrade topics. Learn more
  - The upgrade topics are updated to migrate from Elasticsearch to OpenSearch. Learn more
  - The *Backup and restore with OADP* procedures create a new network policy, and add a new **`esBackupPVC`** parameter. Learn more
  - There are updates to various topics that reference Elasticsearch.
- **(Nonproduction) Multi-zone high availability and disaster recovery (HADR) (IBM Cloud Pak for AIOps on Red Hat OpenShift)**. This feature continues to be hardened, but remains a technology preview. Installation topics are updated with the ability to create an installation resource for a multi zone cluster. Learn more.
- **Resizing storage (IBM Cloud Pak for AIOps on Red Hat OpenShift)** The method for increasing PVC sizes for Cassandra, Postgres, Elasticsearch, and Kafka is updated in v4.8.0. Learn more.
- **Offline deployments no longer retrieve catalogs from the CASE file (IBM Cloud Pak for AIOps on Red Hat OpenShift)**. Offline installation and upgrade procedures are updated for this. Learn more: Offline install and Offline upgrade.
- **Changes to image mirroring (IBM Cloud Pak for AIOps on Red Hat OpenShift)** Image mirroring for offline deployments now uses the **`aiopsctl bastion <..>`** command instead of podman. For more information, see Offline installation: Mirror images and Offline upgrade: Mirror the images.
- **Renewed certificate (IBM Cloud Pak for AIOps on Red Hat OpenShift)** The certificate that is used to sign the IBM Cloud Pak for AIOps images has been renewed, and the new public key is listed in Verifying images. This only affects you if you want to verify the IBM Cloud Pak for AIOps images.
- **New minimum Netcool Operations Insight version requirement (IBM Cloud Pak for AIOps on Red Hat OpenShift)** If IBM® Netcool® Operations Insight® is installed on the same cluster, it must be at version 1.6.13 or higher. Learn more.
- **Incremental adoption (IBM Cloud Pak for AIOps on Linux)** Deployment mode is now configured with a command line argument instead of with a configuration file. Learn more

Defining integrations (connections)

- **Instana integration:** You can now use the Instana Observer instead of the Instana Connector to retrieve topology data from an integration with Instana. **Note** that the Instana Connector will continue to collect event and metric data, but not topology data.
  - See Migrating from the Instana Connector to the Observer for the steps to migrate from the Instana Connector to the Observer.
  - See Configuring Instana Observer jobs for information on using the Instana Observer.

Resolving incidents and alerts

- **Scope-based grouping explainability:** When viewing an incident's alert list, and the selected alert is part of an alert group, the **Alert details** side panel displays information about the underlying temporal, topological, or scope-based groups. For scope-based groupings, you can now click the link **Scope-based policy associated to this alert** to go directly to the associated policy in the Policies UI.

Managing user access control

- **New read-only permission:** The new *View operational data* permission provides users with read-only access to Cloud Pak for AIOps. The *Manage operational data* permission is required to make changes to alerts, incidents, filters, and views. For more information, see Basic operations permissions.

  Important: After upgrading to IBM Cloud Pak for AIOps 4.8.0, users will not be able to perform some tasks until the following permissions are added to existing roles:
  - Manage operational data
  - Use runbooks
  - View topologies

Managing applications (services) and viewing topologies

- **New Instana Observer:** For an integration with Instana, you can now use an Observer integration instead of the previously available integration (Connector type) integration. With this Observer integration, you can retrieve topology data from an integration with Instana.

  Note: The existing Instana (Connector) integration continues to collect event and metric data, but not topology data.

Automating processes (Policies, Runbooks, Actions)

- **Runbook improvements:**
  - You can now administer conditional branching for semi-automated runbooks, as well as fully automated runbooks. For more information, see Adding actions.
  - Automation HTTP actions and client-side actions can now reference unencrypted HTTP endpoints. For more information, see Creating HTTP actions and Creating Client-side actions.
  - There is a new example runbook for expanding Kafka broker storage. For more information, see Sample runbooks with special administrative use cases.
  - Users with the read-only permission `View runbooks` can browse runbooks, actions, and activities. They can not run any runbooks and actions.

Non-production (tech preview)

- **Visualizing analytics with IBM Cognos Analytics:**, the supported capabilities when integrating with IBM Cognos Analytics are improved:
  - You can integrate with IBM Db2 to store alert and incident data in the Db2 database. With this integration, you can create policies to send the alert or incident data from IBM Cloud Pak for AIOps to populate a dashboard or report in IBM Cognos® Analytics.

    For more information about creating this integration, see Creating an IBM Db2 integration. For more information about using policies to send data for a dashboard or report, see Populating a dashboard or report.
  - A new Incident list widget and Button widget are available for use in building a custom dashboard. For more information about the available widgets that you can use, see IBM Cloud Pak for AIOps widgets within IBM Cognos Analytics.
  - Example dashboards are now available to help you learn about the capabiltities of the available widgets and to help you create your own dashboard. For more information about creating a dashboard, see Creating a dashboard.

  Overall, this integration provides you with additional tools to create custom dashboards and reports to visualize and analyze your IBM Cloud Pak for AIOps data. When you set up this integration, you can open IBM Cognos Analytics from the Cloud Pak for AIOps console and begin using IBM Cognos Analytics dashboards to build visualizations of your IBM Cloud Pak for AIOps data, such as alert and topology data.
- **Additional feature previews:** In addition to the integration with IBM Cognos Analytics, IBM Cloud Pak for AIOps includes the following components and features for non-production use as a technology preview:
  - Incident (Story) prioritization from persistence analysis and golden signals extraction
  - Multi-zone high availability and disaster recovery (HADR)
  - New data collection functionality for Dynatrace integration

For more information about these feature previews, see Non-production features (Technology preview).

Infrastructure Automation

- **IBM Cloud Pak for AIOps integration improvements**: The integration between Infrastructure Automation and IBM Cloud Pak for AIOps is improved so that metric data can be sent to IBM Cloud Pak for AIOps in addition to the existing sending of event and inventory data. Metric data syndication is also available through the integration in addition to the existing event and inventory data syndication.
- **Upgrade capability:** You can now upgrade from Version 4.4.x to Version 4.8.0.
- When creating a Terraform Service Catalog item, you now have two options to create a Service Dialog. You can use an existing Service Dialog or create a new Service Dialog. For more information, see Running a Terraform Template from a Service Catalog

Security and compliance

- **Fixed security vulnerabilities:** Fixes and updates are included to address reported security-related vulnerabilities with IBM Cloud Pak for AIOps. For more information about the included fixes, see Security bulletins and fixes.

Documentation changes

In addition to the documentation for the preceding new and changed features, the following documentation is updated:

- **Enrich incidents by using IBM Tivoli Netcool/Impact policy**: If needed, you can enrich Cloud Pak for AIOps incidents with data from external systems. For more information, see Enriching an incident.
- **Maintaining and debugging automation policies:** Effectively maintain your IBM Cloud Pak for AIOps policies and debug issues that might arise. Determine what policies are firing for alerts, find policies that are related to incidents, and use the policy table to discover policy usage and issues. For more information, see Maintaining and debugging automation policies.

Previously introduced features and changes

For more information about new features and changes that were introduced in previous versions of IBM Cloud Pak for AIOps, see:

- What's new in Version 4.7.1
- What's new in Version 4.7.0
- What's new in Version 4.6.1

- What's new in Version 4.6.0
- What's new in Version 4.5.1
- What's new in Version 4.5.0
- What's new in Version 4.4.1
- What's new in Version 4.4.0
- What's new in Version 4.3.0
- What's new in Version 4.2.1
- What's new in Version 4.2.0
- What's new in Version 4.1.2
- What's new in Version 4.1.1
- What's new in Version 4.1.0

Known issues and limitations

Review the known issues for IBM Cloud Pak® for AIOps.

Also, review the troubleshooting documentation for more information on common issues. For more information, see troubleshooting.

- Install and upgrade
- Backup and restore
- Access control
- Identity Management
- Observers and integrations
- IBM Cloud Pak for AIOps and IBM Netcool Operations Insight
- Applications and topologies
- Infrastructure automation
- UI console
- AI model management and training
- ChatOps
- Incidents and alerts
- Policies
- Secure Tunnel
- Runbook Automation
- AIOps Insights
- Ticketing

Install and upgrade

- Unable to reach inventory service
- Limitation on number of instances
- Manual resource adjustments are not persisted
- Services fail to connect to Cassandra
- The `ibm-aiops-orchestrator` pod throws an `OOMKilled` error
- Automatic approval required for installation
- Elasticsearch health status yellow after restoring from a backup
- ChatOps Microsoft Teams integration does not work with a proxy server
- Kafka topics cannot be listed with oc get kafkatopics

Also, review the troubleshooting documentation for more information on common issues. For more information, see troubleshooting.

Unable to reach inventory service

If your system is installed in the same namespace as IBM Cloud Pak® for Network Automation, the connection to the inventory service breaks. This is caused by a clash with another service with the same name.

Workaround: Use the config.yaml file to enforce the correct values for INVENTORY_SERVICE_HOST and INVENTORY_SERVICE_PORT.

Example:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: noi-topology-sizing
  namespace: namespace
data:
  asm: |
    ui-api:
      containers:
        ui-api:
          env:
            - name: INVENTORY_SERVICE_HOST
              value: noi-topology-inventory.namespace.svc
            - name: INVENTORY_SERVICE_HOST
              value: "9178"
```

Limitation on number of instances

IBM Cloud Pak for AIOps and Infrastructure Automation can co-exist on the same cluster, but you cannot have multiple instances of IBM Cloud Pak for AIOps or Infrastructure Automation on the same cluster.

Manual adjustments are not persisted

Custom patches, labels, and manual adjustments to IBM Cloud Pak for AIOps resources (such as increased CPU and memory values) are lost when an event such as upgrade, pod restart, resource editing, or node restart triggers a reconciliation. Reconciliation causes any manually implemented adjustments to be reverted to their original default values. Depending on the parameters that you want to adjust, you might be able to use a custom profile to persist your changes. For more information about custom profiles, see Custom profiles.

Services fail to connect to Cassandra

After you install IBM Cloud Pak for AIOps for a production environment deployment, various services might not be available due to connection issues with Cassandra. To resolve this issue if it occurs, restart Cassandra and the schema creation pods.

The `ibm-aiops-orchestrator` pod throws an `OOMKilled` error

If your environment has many secrets and ConfigMaps, when the **`ibm-aiops-orchestrator`** (lead operator) attempts to build its cache, the operator can exceed its memory allocation and cause a Kubernetes out-of-memory error for the container. This error can prevent the IBM Cloud Pak for AIOps installation from reconciling, blocking the installation from completing.

If you encounter this issue, the operator requires more memory resources to build its cache. Override the subscription resource to increase the memory limits for the pod and avoid the out-of-memory issue.

Automatic approval required for installation

The use of manual approval strategies for InstallPlans in a project (namespace) can affect the IBM Cloud Pak for AIOps installation.

For instance, if you use manual approval for any of your InstallPlans to install operators in **`All Namespaces`** mode (**`cluster`** scope), the manual approval can affect your install. The installation of IBM Cloud Pak for AIOps requires automatic approval to be used.

Elasticsearch health status yellow after restoring from a backup

When you are restoring an Elasticsearch backup to a new single node Elasticsearch cluster, the Elasticsearch database might not work as expected. Instead, the Elasticsearch cluster health shows that a yellow status after the restore completes.

ChatOps Microsoft Teams integration does not work with a proxy server

If you have an offline (air-gapped) deployment of IBM Cloud Pak for AIOps or an environment that uses a proxy server, then you cannot use the ChatOps Microsoft Teams integration. The use of a proxy with the Chatops Microsoft team integration is not supported.

Kafka topics cannot be listed with oc get kafkatopics

Kafka topics are created by using the KafkaTopic custom resource or API. Only topics that are created by custom resource are shown when running **`oc get kafkatopics`**. To see a full list of all the Kafka topics use the following steps:

1. Install kcat.
2. Get the **`waiops-mustgather.sh`** script. For more information, see Installing the IBM Cloud Pak for AIOps MustGather tool.
3. Run **`waiops-mustgather.sh -V kafka-topics`**

Backup and restore

- Backup and restore with Fusion

Backup and restore of IBM Cloud Pak for AIOps with older versions of IBM Fusion does not work with Portworx

If you are using Portworx as your storage provider, then IBM Fusion must be at v2.9.0 or higher, or backup and restore will fail.

Access control

- Automation Analyst role unused in IBM Cloud Pak for AIOps
- Users from a user group remain after user group is deleted
- UI redirects to unexpected page when logging in after a session timeout
- Users in a user group are not listed under the Manage assignees pane of the Incidents and alerts page

Automation Analyst role unused in IBM Cloud Pak for AIOps

By default, an Automation Analyst role is displayed within the IBM Cloud Pak for AIOps console Access control page when you are assigning a role to a user. This default role is used within the IBM® Automation family of offerings, which includes IBM Cloud Pak for AIOps, however, this role is not used within IBM Cloud Pak for AIOps.

This role does not include or provide any permissions within IBM Cloud Pak for AIOps and should not be assigned to users within IBM Cloud Pak for AIOps.

Users from a user group remain after user group is deleted

When you delete a user group, the users that were included in the group remain in your list of users. Any role that is inherited through the deleted user group is removed from the users. If the users were assigned roles individually, they continue to have those roles and can continue to log in to the UI console and complete tasks. If the users that were in the deleted user group need to be removed completely, an administrator needs to manually remove the users. Users can be removed by clicking the *Delete* icon for the user's entry within the list of users on the *Access control Users* tab.

UI redirects to unexpected page when logging in after a session timeout

After a session timeout occurs and a user logs in to the UI console again, the user can be redirected to a different page than the page that they were on when the timeout occurred. For instance, a user that was working on the AI Model Management training page when their session timed out might be redirected to a graphql playground page after logging back in. This redirect occurs because the UI uses the last request URL that included the expired token to identify where to redirect the user when the user logs back in. If this redirect occurs, the user needs to manually return to the expected page in the UI to continue working.

Users in a user group are not listed under the Manage assignees pane of the Incidents and alerts page

When you have users within a user group and view the *Manage assignees* pane of the Incidents and alerts page, you might not see some users who are listed. This error can occur when the users from the LDAP user group are not individually onboarded. To verify whether a user is onboarded, go to the **Access control** > **Users** tab and check whether the user is listed. If the user is not listed, that user must first log in to the console, which validates their roles and permissions. After logging in, the user can display in the list of users and on the *Manage assignees* pane.

The *Manage assignees* pane is viewable from the list of all Incidents. Select an incident and then click *Manage assignees*. After you select an existing user group, you should see the included users who are listed.

Identity Management

The IBM Cloud Pak foundational services Identity Management (IM) service is used by IBM Cloud Pak for AIOps. This service includes the following known issues and limitations:

Note: Some descriptions of the listed known issues in Identity Management are shortened.

- Login failure in Platform UI console while upgrading foundational services version 3.22 or version 3.23 to foundational services version 4.x.x.
- LDAP user names are case-sensitive.
- The OpenShift group does not synchronize when a user is added or removed from an LDAP group.
- The OpenShift users are not removed when you remove them from the LDAP group.
- You cannot onboard OpenShift user group to Identity Management as the groups property of the `user.openshift.io` API is deprecated.

For more information about all the known issues and limitations that are related to Identity Management, see Known issues in foundational services.

Observers and integrations

- Kubernetes Observer job fails to restart after OOM
- ServiceNow Observer UI displays superfluous character
- 'Failed to read certificate' error
- Duplication of resources in the topology if certain observer job parameters are changed after a job has been run
- Incomplete historical data processing in the event of integration pods restarting
- File and Rest observer topology service location URL not accessible
- Integration console displays special characters incorrectly
- Turbonomic integration with IBM Cloud Pak for AIOps affects other integrations in Turbonomic
- No notification in IBM Cloud Pak for AIOps on Turbonomic actions closed without execution
- New Relic observer does not support dashboard tokens for new users
- All dates and time are in US-en format
- Appdynamic historical start date and time cannot be older than 4 hours
- Appdynamic live mode aggregation interval is 1 minute
- The observer-service pod is in crash back loop due to ghost vertex
- Alerts for Instana without associated topologies
- Alerts for Instana topology not mapping properly
- Instana metric collection API rate limit exceeded error
- IBM Cloud Pak for AIOps cannot close some alerts when an Instana integration exists
- Delay query time for integrations
- When creating a kubernetes observer job that is named 'weave_scope', 'load', 'kubeconfig', or 'local', the job fails to run
- Log Anomaly 8k limit on field mapping in details field of the alert schema
- Log integration does not start when multiple log integrations are active
- After a restore, data from integrations is not processed
- Historical data from ServiceNow instance gets collected only when the historical data flow is reenabled
- Dynatrace integration pod restarted and does not retrieve all historical data
- ServiceNow user account gets locked out after a few hours
- Scale resources when running log anomaly training on large data
- The integration status for Elk, Custom Logs, Mezmo, and Falcon LogScale sometimes show 'not running' even though the Flink job and gRPC pod are running correctly
- Log data integrations status is "Done" even though historical data is still loading
- IBM Tivoli Netcool/Impact integration stops event processing with exceptions
- Impact integration fails for Impact server with non-default cluster name
- Connector experienced a failure due to a Bad Request for connection when data flow was enabled
- GitHub connector issues with similar tickets and adding assignees to mappings
- ServiceNow ticket contains too much text
- ServiceNow user account locked out
- ServiceNow observer status given as `Unknown` for an extended period
- Integrations unable to pause and resume both inbound and outbound data flow
- Dynatrace topology does not support proxy target system
- Error messages in the agent log when the Dynatrace integration is disabled
- Dynatrace topology unable to create a second instance on the same cluster

- Output to Db2 via the connector is not keeping up
- When using the Db2 integration, data may not be in sync when using an update trigger in a policy
- Db2 integration shows a status of Running regardless of whether correct login details have been specified
- Integrations stuck in Initializing state
- New Relic observer job fails with an authorization error

Kubernetes Observer job fails to restart after OOM

Kubernetes Observer jobs with very large payloads can encounter an OOM (out-of-memory) error, after which they may fail to restart. The observer appears offline, but a health check fails to flag any errors.

Workaround: Restart the observer if it appears as offline in the UI.

ServiceNow Observer UI displays superfluous characters

If the Entity_mapping field is updated from the Observer UI, superfluous curly brackets and quotations are displayed in the Resource type-mapping field.

Workaround: This is a cosmetic issue and can be ignored.

'Failed to read certificate' error

This error can occur when an observer attempts to create an SSL certificate and the endpoint server does not respond.

In the example error message below, a vmvcenter.crt certificate error occurs because the endpoint server does not respond.

```
Failed to read certificate for field [certificate].
The file 'vmvcenter.crt' could not be found under /opt/ibm/netcool/asm/security/.
```

Workaround: Ensure that the endpoint server is running correctly.

Duplication of resources in the topology if certain observer job parameters are changed after a job has been run

Certain resource parameters are used to uniquely identify a resource. If one of these parameters is changed after the initial job run, then any subsequent job run will result in duplicate records. For example, if the parameter of 'hostname' is replaced with 'Ipaddress' after a topology has been created, a subsequent discovery will consider the resource as new, and create a duplicate record.

The following resource parameters uniquely identify a resource. Changing them after the initial job has been run will result in duplicate records.

Workaround: If you need to modify these values, do not modify the existing job. Instead, create a new job.

Table. Observer job parameters

Observer	Job parameter
ALM	n/a
AppDynamics	`account`
AWS	`region`, `dataTenant`
Ansible AWX	`host`, `user`
Azure	`data_center`
BigFix Inventory	`data_center`
Big Cloud Fabric	`proxy-hostname`, `proxy-username`, `bcf-controllers`
Ciena Blue Planet	`data_center`, `tenant`
Cisco ACI	`tenant_name`
DNS	`addressTypes`, `server`, `port`, `recurse`
Docker	`endPoint.port`
Dynatrace	`datatenant`, `hostname`
File	`provider`, `file`
GitLab	`datatenant`, `hostname`
GoogleCloud	`project_id`
HPNFVD	`datacenter`, `username`, `cnf_job`
IBM Cloud	`instance`, `username`, `region`
ITNM	`instance`
Jenkins	`jenkins_observation_namespace`
Juniper CSO	`cso_central_ms_url`, `user_domain_name`, `domain_project_tenant_name`
Juniper Contrail	`api_server_url`, `os_project_name`, `os_tenant_name`
Kubernetes	`data_center`, `namespace`
NewRelic	`accountName`, `accountId`
OpenStack	`data_center`, `os_project_name`
Rancher	`accessKey`, `clusterId`
REST	`provider`
SDC ONAP	`host`, `username`
ServiceNow	`instance_url`, `username`
SevOne	`datatenant`, `hostname`
TADDM	`api_url`, `username`
Viptela	`data_center`
VMware NSX	`data_center`
VMware vCenter	`data_center`

Observer	Job parameter
Zabbix	`data_center`

Incomplete historical data processing in the event of integration pods restarting

If you create an integration to collect historical data for Metric Anomaly AI Training, you might come across an issue where the integration pod restarts, but does not retrieve all historical data for training. As a result, you might suffer data loss.

An integration pod can restart due to outages, the target system crashing, or pod crashes in the environment. This issue can occur intermittently, depending on the number of metrics that are selected for the integration and the amount of data to be retrieved.

File and Rest observer topology service location URL not accessible

When creating an edge via either the File or Rest observers, the POST request returns a Topology service location URL that is not accessible. The URL cannot be used to manage the edge because the relevant API is not exposed. **Workaround:** None

Integration console displays special characters incorrectly

If you use special characters in the **Name** and **Description** fields while creating or editing an integration, the console *Integrations* page might display the special characters incorrectly. Nevertheless, the integration is saved.

Turbonomic integration affects other integrations in Turbonomic

The Turbonomic integration with IBM Cloud Pak for AIOps enables actions that are created or executed in Turbonomic to be notified in IBM Cloud Pak for AIOps through the enabled webhook workflow. However, Turbonomic allows only one webhook workflow per action. Therefore, other integrations that are enabled in Turbonomic, like ServiceNow, might not get any notification when actions are created or executed in Turbonomic.

No notification in IBM Cloud Pak for AIOps on Turbonomic actions closed without execution

IBM Cloud Pak for AIOps does not receive any notification from Turbonomic for actions that are closed without being executed. For example, an action related to an erroneous condition that is no longer occurring gets automatically closed in Turbonomic. But its corresponding IBM Cloud Pak for AIOps alert remains open indefinitely and must be cleared manually from the console.

New Relic observer does not support dashboard tokens for new users

For *new users* of the New Relic observer, the observer does not work as it no longer supports the New Relic One dashboard token. However, it will continue to work for *existing users* who are using the old token that was generated previously through the old dashboard.

All dates and time are in US-en format

When you are scheduling data collection for a integration, all dates and times are presented in the US-en formats:

- All dates are configured and presented in the `mm/dd/yyyy` format.
- All times are configured and presented in the `hh:mm AM/PM` 12-hour clock format.

You cannot switch the date or time format.

Appdynamic historical start date and time cannot be older then 4 hours

Historical start date and time is configurable, but if you set it to beyond the past 4 hours, then the integration will ignore it and only retrieve the past 4 hours of data.

Appdynamic live mode aggregation interval is 1 minute

In live mode, the new aggregation interval allowed is only 1 minute.

The observer-service pod is in a crash back loop due to a ghost vertex

If you notice that the topology observer-service pod is not functioning correctly and that restarting the pod does not correct the issue, a ghost vertex might need to be removed. To remove the vertex, you need to traverse an edge to the vertex, and then delete the vertex. To traverse to the vertex, use the type vertex and definesType edge.

1. Run the following command to find the ID for the type vertex.

   ```
   oc exec -it <topology pod> -- curl -X GET --header 'Accept: application/json' --header 'X-TenantID: 01abea99-8dff-7f71-bef3-09136b6a4ff0' 'https://localhost:8080/1.0/topology/types?_filter=keyIndexName=ASM::entityType::mgmtArtifact::ASM_OBSERVER_JOB' -u <username><password> --insecure
   ```

   Where

   - `<username>` - Your Topology IBM Cloud Pak for AIOps API username
   - `<password>` - Your Topology IBM Cloud Pak for AIOps API password
2. Run the following command to use the definesType edge to get the ID for the vertex that is causing the issue.

   ```
   oc exec -it <topology pod> -- curl -X GET --header 'Accept: application/json' --header 'X-TenantID: 01abea99-8dff-7f71-bef3-09136b6a4ff0'  'https://localhost:8080/1.0/topology/resources/<type vertex ID>/references/out/definesType' <username><password> --insecure
   ```

   Where

   - `<type vertex ID>` - The ID for the type vertex that you retrieved in step 1.
   - `<username>` - Your Topology IBM Cloud Pak for AIOps API username
   - `<password>` - Your Topology IBM Cloud Pak for AIOps API password
3. Run the following command to delete the vertex.

```
oc exec -it <topology pod> -- curl -X DELETE --header 'Accept: application/json' --header 'X-TenantID: 01abea99-8dff-7f71-bef3-09136b6a4ff0' 'https://localhost:8080/1.0/topology/resources/<type vertex ID>/references/out/definesType?_delete=nodes&_delete_self=false&_node_label=vertex' -u <username><password> --insecure
```

Where

- `<type vertex ID>` - The ID for the type vertex that you retrieved in step 1.
- `<username>` - Your Topology IBM Cloud Pak for AIOps API username
- `<password>` - Your Topology IBM Cloud Pak for AIOps API password

Delay query time for integrations

If you set an integration to retrieve *Live data for continuous AI training and anomaly detection* or *Live data for initial AI training*, you might need to configure a delay to offset the query time window to provide a time buffer for preventing the partial retrieval of real-time data. You cannot configure this delay within the UI console. You must use a command line to configure the delay. For more information about configuring this delay, see Delay configuration in data integrations.

Alerts for Instana without associated topologies

In some cases Instana alerts will not have associated topologies. In most cases this happens because the resource that originated the event is no longer available in Instana. For example, a pod that triggers an Instana event can be redeployed by the underlying kubernetes engine.

Alerts for Instana topology not mapping properly

In some cases alerts are not mapped correctly to a corresponding Instana topology node. For example, alerts generated from log anomaly detection or metric anomaly detection (or other sources) might not show as associated with a Instana topology node.

As a workaround, you need to define your own match rules to correlate with the source data. To define a match rule, click on **Resource Management**, then click **Settings**, **Topology Configuration**, and finally **Configure** on the *Rules* Tile. When you are configuring the match token values to use, the values depend on the data that you are sending to Instana.

Instana metric collection API rate limit exceeded error

The recommended rate limit will be double the number of resources. There might be situations where the limits need to be increased. When a more precise limit is required, use the following formula to determine the limit to use:

```
number-of-metric-API-calls-per-hour ~= (number-of-selected-technologies x 2) x (snapshots-for-selected-technologies / 30) x (60 / collection-interval)
number-of-topology-API-calls-per-hour ~= (number-of-application-perspectives x (60 / collection-interval)) +(number-of-services x (60 / collection-interval))
number-of-events-API-calls-per-hour = 60

total= number-of-metric-API-calls-per-hour + number-of-topology-API-calls-per-hour + number-of-events-API-calls-per-hour
```

Note: Each plugin can have a different number of metrics collected. The mean value across these is used, which is 2 collection cycles per plugin. If the environment is unbalanced, for instance you have mostly hosts that define most metrics, then the formula might underestimate the required limit.

To determine the number of resources (snapshots) for each infrastructure pluginAPI, use the following:

```
api/infrastructure-monitoring/snapshots?plugin=technology_name
```

Example:

```
api/infrastructure-monitoring/snapshots?plugin=host
```

For more information about Instana APIs, see Instana API.

The following example curl commands allow you to retrieve the number of:

- snapshots-for-selected-technologies (such as host)

  ```
  curl -k -s --request GET 'https://<instana server hostname>/api/infrastructure-monitoring/snapshots?plugin=host' --header 'Authorization: apiToken <api token>' | jq '.items|length'
  ```

- number-of-application-perspectives

  ```
  curl -k -s --request GET 'https://<instana server hostname>/api/application-monitoring/applications' --header 'Authorization: apiToken <api token>' | jq '.items|length'
  ```

- number-of-services

  ```
  curl -k -s --request GET 'https://<instana server hostname>/api/application-monitoring/services' --header 'Authorization: apiToken <api token>' | jq '.items|length'
  ```

IBM Cloud Pak for AIOps cannot close some alerts when an Instana integration exists

If you have an Instana integration created and have Instana 221 (Saas or Self-Hosted), you might encounter an issue where IBM Cloud Pak for AIOps might not be able to close some alerts. Instead, you might need to check the status for the associated event within the Instana dashboard and clear the alert manually. For more information, see Troubleshooting integrations: Instana Event integration.

When creating a Kubernetes observer job that is named 'weave_scope', 'load', 'kubeconfig', or 'local', the job fails to run

If you create a Kubernetes observer job with the name `weave_scope`, `load`, `kubeconfig`, or `local`, the job always fails to run. When this error occurs, you can view an error icon in the schedule column for the job. To avoid this issue, do not use these names for the observer job.

Log Anomaly 8k limit on field mapping in details field of the alert schema

The limitation is that the datalayer imposes an 8 kb size limit on the details field in the alert schema. The details field is populated by the log anomaly event, which provides the relevant information to display in slack when trying to view alerts in the chatops. Whenever the details field size exceeds 8 kb, the returned json object is truncated and therefore when the user clicks **view alerts** to retrieve the alerts related to an incident, expected results are not seen and an error is recorded.

The current fields under the details objects are:

```
end_timestamp: int
original_group_id: str
causality: dict
detected_at: float
source_application_id: str
log_anomaly_confidence: float
log_anomaly_model: List[str]
prediction_error: dict
error_templates: List[int]
count_vector: List[int]
text_dict: dict
application_group_id: str
application_id: str
model_version: str
severity_from_model: int
description: str
```

Log integration does not start when multiple log integrations are active

If you have many active log integrations, such multiple Kafka, ELK, Splunk, and Falcon LogScale integrations, and you create and enable another Falcon LogScale integration, you might notice that the integration status is stuck in an error or restarting state. This state can even occur after the integration is operating as expected.

This can occur if you exceed the limit for the number of jobs that can run on the underlying service, which results in insufficent resource available to start the integration. To resolve this issue, complete one or more of the following tasks:

- Increase the replica count of your task managers.
- Increase the task manager count per replica.
- Change the parallelism of your integrations.
- Cancel other integrations

After a restore, data from integrations are not processed

If you have an integration that you are restoring, the status for these integrations can be in error after the restore process completes. To resolve this status, you need to edit and save your integrations with the Integrations in the IBM Cloud Pak for AIOps IBM Cloud Pak for AIOps console. Editing the integration regenerates the associated Flink job for the integration, which updates the status.

Historical data from ServiceNow instance gets collected only when the historical data flow is reenabled

If you enable historical data flow for a ServiceNow integration, you might notice that the historical data is not collected from ServiceNow. For instance, when you check the **`grpc-snow`** pod, you can see ticket data available, but when you check the Flink job or in Elasticsearch, you can notice that no data was collected. If this issue occurs, turning off the historical data flow and turning it back on can cause the data to begin to be collected.

Dynatrace integration pod restarted and does not retrieve all historical data

If you have a Dynatrace integration created and pull historical data with multiple metrics for Metric Anomaly AI Training, you can encounter an issue where the Dynatrace pod restarts, but does not complete retrieving the expected historical data for training. This issue can occur intermittently, depending on the number of metrics that are selected for the integration and the amount of data to be retrieved.

If this potential out-of-memory or out-of-resources issue occurs, consider creating separate integrations to monitor different and smaller sets of metrics. By splitting the integrations, you can reduce the amount of data to be retrieved through the initial integration that can cause this issue.

ServiceNow user account gets locked out after a few hours

If there is an active ServiceNow integration with data collection enabled and the ServiceNow credentials change, the ServiceNow user account can get locked out. ServiceNow has an automatic login locking script called "SNC User Lockout Check", which locks users out after more than 5 failed attempts (including any failed API calls).

If you check the Incidents and alert page, you will see also an alert saying "ServiceNow instance authentication failed".

When this problem occurs, unlock the user in ServiceNow. Then change the password in the ServiceNow integration and save. When authentication fails in the ServiceNow integration, there is a 1-minute wait time before you can access it, to prevent a lockout from occuring quickly.

Scale resources when running log anomaly training on large data

In some cases it is observed that log anomaly training fails on large data due to being Out Of Memory (OOM) or if there is a problem with ES shards. The solution is to scale up the resources to handle large data training.

For more information about shard management, see About indices and shards. For more information about increasing ES Resources, see Log anomaly training pods CPU and Memory resource management.

The integration status for Elk, Custom Logs, Mezmo, and Falcon LogScale sometimes shows 'not running' even though the Flink job and gRPC pod are running correctly

On creating a integration, the Flink job retrieves data normally and the gRPC pod is running without error. However, the console shows that the integration status is 'not running'.

Log data integrations status is "Done" even though historical data is still loading

When a log data integration (Falcon Logscale, ELK, Mezmo, Custom, Splunk) is running in **Historical data for initial AI training** mode, and a custom regex is added in the `field_mapping` section, the data processing can take a long time. Although the **Data collection status** might be shown on the UI as **Done**, data could still be being processed and written to Elastic in the background.

To speed up this process, you can increase the **Base parallelism** number that is associated with that integration. For more information, see Increasing data streaming capacity.

IBM Tivoli Netcool/Impact integration stops event processing with exceptions

If you have an IBM Tivoli Netcool/Impact integration, you can encounter an issue where the integration temporarily stops processing during the sending of an event stream to IBM Cloud Pak for AIOps.

This issue can occur when you have an IBM Cloud Pak for AIOps policy that triggers an IBM Tivoli Netcool/Impact policy when certain types of events are received. If this issue occurs and stops the event processing, the Impact integration logs or Impact policylogger logs can include messages that are similar to the following example exceptions:

```
[6/14/23, 11:38:45:816 UTC] 0000005d ConnectorMana W failed to send status update
...
[6/14/23, 11:38:45:815 UTC] 000023ca StandardConne W configuration stream terminated with an error
...
[6/14/23, 11:38:45:816 UTC] 000023cc GRPCCloudEven W consume stream terminated with an error: channel=cp4waiops-cartridge.lifecycle.output.connector-requests
```

If you encounter this issue, you might need to restart the `impact-connector` pod to begin the processing of the event stream again.

IBM Tivoli Netcool/Impact integration fails for IBM Tivoli Netcool/Impact server with non-default cluster name

If the IBM Tivoli Netcool/Impact cluster uses a non-default cluster name ("NCICLUSTER"), the integration can fail to validate the integration. The IBM Tivoli Netcool/Impact server may report `DynamicBindingException` errors in the impactgui.log:

```
com.micromuse.common.nameserver.DynamicBindingException: DynamicBindingException: Service [NCICLUSTER] not in nameserver.
```

To resolve the issue, wait for the backend IBM Tivoli Netcool/Impact server to finish initializing before starting or restarting the Impact GUI server.

If IBM Tivoli Netcool/Impact is running fix pack 7.1.0.26 or later, you can also resolve the issue by setting the `nameserver.defaultcluster` property in the GUI server. Add the following line to *$IMPACT_HOME/etc/nameserver.props*:

```
impact.nameserver.defaultcluster=CLUSTERNAME
```

where *CLUSTERNAME* is the name of the IBM Tivoli Netcool/Impact cluster.

IBM Cloud Pak for AIOps and IBM Netcool Operations Insight

- IBM Cloud Pak for AIOps Strimzi Kafka topics created without replication
- IBM Cloud Pak for AIOps pods not starting after a cluster restart
- NOIHybrid incorrectly listed in provided APIs for IBM Netcool Operations Insight operator
- Rare issue: unable to deploy log anomaly detection model

IBM Cloud Pak for AIOps Strimzi Kafka topics created without replication

IBM Cloud Pak for AIOps supports multiple replications of Kafka topics for large production installations, such as for data redundancy. The IBM Cloud Pak for AIOps console can automatically create Kafka topics when integrations are created. When a topic is dynamically created by the IBM Cloud Pak for AIOps console, the replication is set to `1` in the controller. As such, Kafka topics the are created during installation can have multiple replicates, but those topics that are created dynamically do not.

If you are implementing a production (large) deployment of IBM Cloud Pak for AIOps, you might lose data if your Kafka pods fail or restart. If the data flow is enabled in your Kafka integration when the Kafka pods go down, you might experience a gap in the data that your integration generated during that down period. Upgrades or updates to workers can cause a Kafka broker restart.

You can manually modify the Kafka topic replication inside the Kafka container from a value of `1` to `3` to mitigate any potential data loss from this issue.

IBM Cloud Pak for AIOps pods not starting after a cluster restart

When the cluster is restarted, all nodes have a *STATUS* of *Ready*. Most pods return to a *STATUS* of *Running* except for some IBM Cloud Pak for AIOps pods.

One potential cause is that Elasticsearch must be up and running before the IBM Cloud Pak for AIOps pods can start.

Restart the Elasticsearch pod to get all pods back to a *STATUS* of *Running*.

NOIHybrid incorrectly listed in provided APIs for IBM Netcool Operations Insight operator

NOIHybrid is incorrectly included in the **Provided APIs** list for the IBM Netcool Operations Insight operator. This list is displayed in the Red Hat OpenShift Container Platform web console under **Installed Operators** > **Netcool Operations Insight** > **Operator Details**. Do not use *NOIHybrid* APIs.

Rare issue: unable to deploy log anomaly detection model

Very occasionally, following successful completion of log anomaly detection training, an error similar to the following is displayed in the AI management UI training page following an attempt to deploy the model.

```
Error
Model deployment failed
```

Within the error textbox, you will also see the text "**Forbidden**".

If you investigate the **aiops-ai-model-ui** pod logs, you will also see the following error.

```
ForbiddenError: invalid csrf token
```

If this occurs, first refresh the browser and try to deploy again.

If that does not remedy the situation, then log out and log back in, and then try to deploy the model again.

Connector experienced a failure due to a Bad Request for connection when data flow was enabled

When data flow is enabled for the Splunk connector, the connection fails with a `Bad Request for connection` error.

Workaround: Check that the models are deployed correctly. Then deploy the models in the AI hub UI.

GitHub connector issues with similar tickets and adding assignees to mappings

The following known issues have been obeserved with the GitHub connector:

- In the Incident **Overview** > **Add tickets to this incident** panel, GitHub issues are missing the *Updated by* information. Additionally, searching for GitHub similar past resolution tickets from the **Source** drop-down menu in this panel will not display any tickets.
- The GitHub connector might be missing from the list of integrations in training modules such as Similar tickets and Change risk.
- The default issue mappings in a GitHub integration does not have assignees. However, if assignees are added to the mappings issues are not created in GitHub.

ServiceNow ticket contains too much text

If the ServiceNow change request, incident, or problem contains a large amount of text, such as work notes with close to 150,000 characters, the ticket is dropped and a warning is logged in the pod log. Dropping the ticket affects change risk for that ticket, as it will not occur or that ticket will not be used for similar ticket detection.

ServiceNow user account locked out

If there is an active ServiceNow integration with data collection enabled and the ServiceNow credentials change, the ServiceNow user account can get locked out. ServiceNow has an automatic login locking script that is called "SNC User Lockout Check", which locks users out after more than five failed attempts (including any failed API calls).

If you check the *Incidents and alert* page, you see also an alert saying "ServiceNow instance authentication failed".

When this problem occurs, unlock the user in ServiceNow. Then, change the password in the ServiceNow integration and save. When authentication fails in the ServiceNow integration, there is a 1-minute wait time before you can access it, to prevent a lockout from occurring quickly.

ServiceNow observer status given as `Unknown` for an extended period

There is currently a known issue whereby the status of the ServiceNow observer in the UI may be shown as `Unknown` for an extended period (up to 15 minutes) following a successful initialization before finally changing to `Running`. This issue is intermittent. It does not happen every time the ServiceNow observer is started, and it does not affect data collection.

Integrations unable to pause and resume both inbound and outbound data flow

Integrations with bi-directional data flow does not completely pause the flow of data both inbound to AIOPs and outbound from AIOps when the data flow is disabled in the UI.

Currently, when data flow is disabled, only the inbound data flow from the event source to IBM Cloud Pak for AIOps is disabled. Outbound data (in the form of actions) are still being pushed from IBM Cloud Pak for AIOps to the event source. This could cause some alerts being out of sync between the two systems.

Workaround: As a workaround you can resynchronize the alerts from Netcool and AIOps using the following steps:

1. Disable the existing Netcool connector dataflow in the UI. This is to ensure that the connector releases any file locks before deletion.
2. Get the existing Netcool connection ID.
3. Delete the Netcool connection from the UI.
4. Clear the AIOpsAlertId and AIOpsState columns in Netcool alerts.status table.
5. Close AIOps Alerts using the connectionId as a filter.
6. Install a new Netcool connection.

Getting the existing Netcool connection ID

1. Get the connector name.

   ```
   oc get connectorconfiguration -l aiops.connector.type=netcool-connector
   ```

2. Set the `connectionname` variable with the connection name and `namespace` variable with the AIOps namespace.

   ```
   connectionname="netcool"
   namespace="aiops"

   oc project $namespace
   connconfig=$(oc get connectorconfiguration --no-headers | grep "$connectionname" | awk '{print $1}')
   connconfiguid=$(oc get connectorconfiguration $connconfig -o jsonpath='{.metadata.uid}')
   ```

3. Make a note of the connection ID value which will be used in the subsequent steps. Make sure the variable is not empty before proceeding to the next step.

   ```
   echo $connconfiguid
   ```

Clearing the `AIOpsAlertId` and `AIOpsState` columns in Netcool `alerts.status` table

1. Login to the ObjectServers using the NCO_SQL **($OMNIHOME/bin/nco_sql)** utility and execute the following command:

```
-- Clear AIOps columns
update alerts.status set AIOpsAlertId='',AIOpsState='';
go
```

2. Exit the NCO_SQL utility.

Closing AIOPs Alerts using the `connectionId` as a filter

1. Find one of the **ir-core-ncodl-std** pods.

```
$irCorePod=$(oc get pods --no-headers | grep 'ir-core-ncodl-std' | awk '{print $1}' | head -n 1)
```

2. Get into the pod terminal.

```
oc exec -it $irCorePod -- /bin/bash
```

3. Update the command and replace **<connectionId>** with the value from the previous command. This command will list all alerts matching the filter.

```
curl --insecure -X GET -H "Content-Type:application/json" -H "Accept:application/json" \
--user "${API_AUTHSCHEME_STATICKEY_USERNAME}:$(cat ${API_AUTHSCHEME_STATICKEY_PASSWORD_FILE})" \
"https://localhost:10011/irdatalayer.aiops.io/v1/cfd95b7e-3bc7-4006-a4a8-a73a79c71255/alerts?
filter=sender.connectionId%3D%27<connectionId>%27"
```

Example command with **a4e3c212-5f84-4be3-989b-d3f293f0183e** as the **sender.connectionId** filter.

```
curl --insecure -X GET -H "Content-Type:application/json" -H "Accept:application/json" \
--user "${API_AUTHSCHEME_STATICKEY_USERNAME}:$(cat ${API_AUTHSCHEME_STATICKEY_PASSWORD_FILE})" \
"https://localhost:10011/irdatalayer.aiops.io/v1/cfd95b7e-3bc7-4006-a4a8-a73a79c71255/alerts?
filter=sender.connectionId%3D%27a4e3c212-5f84-4be3-989b-d3f293f0183e%27"
```

4. Execute the following command to close alerts matching the **sender.connectionId** filter.

```
curl --insecure -X PATCH -H "Content-Type:application/json" -H "Accept:application/json" \
--user "${API_AUTHSCHEME_STATICKEY_USERNAME}:$(cat ${API_AUTHSCHEME_STATICKEY_PASSWORD_FILE})" \
"https://localhost:10011/irdatalayer.aiops.io/v1/cfd95b7e-3bc7-4006-a4a8-a73a79c71255/alerts?
filter=sender.connectionId%3D%27a4e3c212-5f84-4be3-989b-d3f293f0183e%27" -d '{"state": "closed"}'
```

5. Alerts from the old connection should now be closed.

Dynatrace topology does not support proxy target system

The Dynatrace topology feature in the Dynatrace metrics, events, and topology integration does not currently support a proxy target system.

Error messages in the agent log when the Dynatrace integration is disabled

There is currently a known issue whereby you may see the following error messages if you disable the Dynatrace integration:

```
java.lang.ArrayIndexOutOfBoundsException
Skipping concurrent rule based metrics collection
```

Dynatrace topology unable to create a second instance on the same cluster

Currently Dynatrace topology only allows you to create a single local deployment in a cluster. If you attempt to create a second Dynatrace topology instance using another name, the attempt will fail and no new pods will be created in the cluster.

Output to Db2 via the connector is not keeping up

There is currently a known issue with the IBM Db2 integration whereby even at a very low alert rate, the output to the Db2 instance using the connector is not able to keep up. If you are expecting an alert rate of around 700/s, you will see the data in your DB2 instance appear with a delay in seconds.

Workaround: Increase the resource management and HPA on both the **IntegrationRuntime** and **Db2** connector pods.

When using the Db2 integration, data may not be in sync when using an update trigger in a policy

There is currently a known issue with the IBM Db2 integration whereby the data in the INCIDENTS_REPORTER_STATUS table may not be in sync with AIOps updates if you are using an update trigger in the policy.

When there is just a create trigger in the policy, the data is valid. But if you are using an update trigger, the updates are happening asynchronously, so the latest update can be overridden with the previous update if they are happening at the same time.

There is no workaround currently available.

Db2 integration shows a status of Running regardless of whether correct login details have been specified

There is currently a known issue with the IBM Db2 integration whereby the **Data collection status** of the Db2 integration always displays a green tick to indicate that it is running even if incorrect login details have been specified when creating or updating the IBM Db2 integration.

There is no workaround currently available. If the Db2 connector does not return any table or the Db2 database appears not to be receiving incident or alert data, check the log files to see whether you have specified the Db2 login details correctly, and update the **Username** and **Password** fields in the IBM Db2 integration accordingly.

Integrations stuck in Initializing state

There is currently a known issue whereby integrations occasionally appear to be stuck in the Initializing state.

This issue will resolve itself after a delay.

New Relic observer job fails with an authorization error

You might notice that the New Relic observer job fails due to an authorization error. The issue occurs due to changes in the New Relic API.

The error can resemble the following example:

```
ERROR  [2025-02-06 16:02:51,209] [pool-12-thread-1] c.i.i.t.o.n.j.NewRelicLoadJob -  Failed to validate connection:
javax.ws.rs.NotAuthorizedException: HTTP 401 Unauthorized
```

There is no workaround currently available.

Applications and topologies

- Composite resources with differing geolocation markers are plotted separately in the Resource map
- Resources with a _compositeId value have 'Related Services' and 'Related resource groups' tabs disabled
- JVM heap out-of-memory (OOM) failures when loading large number of resources
- Critical error message displayed when attempting to render an application
- Different date and time in Cloud Pak for AIOps console and ChatOps between users
- Deleting a tag template can cause out-of-memory errors
- The Find Path tool ignores filters
- Fault localization and blast radius are not producing accurate results
- High volumes of data can cause Spark workers to run out of memory
- Probable cause is not producing accurate results
- Azure observer missing subnet relationship in topology
- Topologies not visible on Incident Topology page after resource merge
- Openstack observer missing edge-runsOn connectivity in topology
- Topology viewer user interface crashes after the update manager is displayed

Composite resources with differing geolocation markers are plotted separately in the Resource map

On rare occasions a composite resource may contain more than one geolocation marker. All of these will be plotted on the Resource map. If one of these locations falls outside the displayed map area, its status is not displayed.

Workaround: None. Be aware of this quirk when viewing composite resource on the Resource map.

Resources with a _compositeId value have 'Related Services' and 'Related resource groups' tabs disabled

Group and service information cannot be fetched for resources that are part of a composite.

This defect is only encountered when viewing the related service or related resource group details of a resource that is part of a composite. This resource will have the 'Related services' and 'Related resource groups' tabs disabled.

Workaround: none

JVM heap out-of-memory (OOM) failures when loading large number of resources

When running topology loads in quick succession, it is possible to experience some OOM errors and undesired topology pod restarts, even though the pods will continue the processing after restarting.

This error can occur when running resource loads of several millions in a large deployment, and could slow down the loading process. The following type of error message can be seen in the pod logs:

```
WARN [2022-10-25 15:43:31,906] [JanusGraph Session-io-4] c.d.o.d.i.c.c.CqlRequestHandler - Query '[4 values] SELECT
column1,value FROM janusgraph.graphindex WHERE key=:key AND column1>=:slicestart AND column1<:sliceend LIMIT :maxrows
[key=0x02168910cfd95b7e3bc74006a4a8a73a79c71255a0726573...<truncated>, slicestart=0x00, sliceend=0xff,
maxrows=2147483647]' generated server side warning(s): Read 5000 live rows and 1711 tombstone cells for query SELECT
value FROM janusgraph.graphindex WHERE key = 02168910cfd95b7e3bc74006a4a8a73a79c71255a07265736f757263e5 AND column1 >
0039247011800128715902900128715002900 AND column1 < ff LIMIT 5000; token 9157578746393928897 (see
tombstone_warn_threshold) JVMDUMP039I Processing dump event "systhrow", detail "java/lang/OutOfMemoryError" at 2022/10/25
15:43:32 - please wait. JVMDUMP032I JVM requested System dump using '/tmp/cassandra-
certs/core.20221025.154332.1.0001.dmp' in response to an event
```

Cause: Not enough headroom exists between JVM memory limit and the pod memory limit, usually because one was increased without also increasing the other.

Workaround: Ensure that any changes in heap size maintain enough headroom between these settings.

Example: In this example (for a topology size1) the pod limits are set to 3.6 GB while the maximum memory for the JVM (`-Xmx`) is set to 3 GB, thereby leaving 0.6 GB of headroom free for use by the OS.

```
size1:
   enableHPA: false
   replicas: 2
   jvmArgs: "-Dcom.ibm.jsse2.overrideDefaultTLS=true -Xms1G -Xmx3G"
   resources:
      requests:
         memory: "1200Mi"
         cpu: "2.0"
      limits:
         memory: "3600Mi"
         cpu: "3.0"
```

Critical error message displayed when attempting to render an application

This problem occurs when all of the groups, within the application you are attempting to render, have no members. When the application is selected in **Application management**, it does not render and a critical error message is displayed on the UI.

Avoid creating applications with no members. If an application with no members was created for test purposes only, then ignore this error.

Different date and time in Cloud Pak for AIOps console and ChatOps between users

The date and time format for an Incident in the IBM Cloud Pak for AIOps console *Application management* tool and the associated ChatOps notification can be different between users. The format and time zone that is used in the Cloud Pak for AIOps console and ChatOps notification is set to the user's locale. If different users are in different time zones, the displayed date and time are different in the Cloud Pak for AIOps console and ChatOps notification.

Deleting a tag template can cause out-of-memory errors

If a tag is applied to a large number (that is, thousands) of topology resources, then deleting the tag template can cause out-of-memory errors with the **`topology-merge`** pod.

Avoid creating tag templates that use tags that occur with such frequency. Later, do not tag thousands of resources with the same tag, and avoid them being used in a group.

The Find Path tool ignores filters

The topology path tool fails to launch with filters applied.

Launch the path tool without filters, then manually apply the filter settings on the path page.

Probable cause is not producing accurate results

The correlation algorithms for probable cause currently require the use of a Kubernetes model with service-to-service relationships, or the use of dependency relationships between non-Kubernetes resources.

Complete the following steps to create the required relationships for Kubernetes. This procedure configures Topology Manager to overlay relationships provided by the File observer onto the Kubernetes topology.

Note: The Kubernetes observer must be configured and loading data.

1. Log in to the IBM Cloud Pak for AIOps console.
2. From the main navigation, expand **Operate** and click **Topology viewer**.
3. From the topology navigation toolbar, expand **Settings**, click **Topology configuration**.
4. On the **Rules** tile, click **Configure** to navigate to the *Rules administration* page.
5. On the **Merge** tab, click **New** to create a **New merge rule**.

   In this scenario, data that is provided by the File observer will be used to add the relationships.
6. Specify the following information on the **New merge rule** page:
   1. Rule name: **`k8-file-service`**.
   2. Set the rule Status to **Enabled**.
   3. Add the **`uniqueId`** property to the set of Tokens.
   4. Expand the **Conditions** section and select **File** and **Kubernetes** from the set of available Observers and click **Add**.
   5. Specify **`service`** for **Resource types** and click **Add**.
   6. Click **Save** to save the new Merge rule.
7. Locate the services that you want to relate together and make a note of their source-specific uniqueId, such as **`05f337a1-5783-43bb-9323-dfba941455c7`** (shipping) and **`ae076382-3df9-46cb-97e9-a0342d219efb`** (web).
8. Create a file for the File Observer that contains the **`service-dependsOn-service`** relationships necessary for the correlation algorithms to work.

   The following example creates two services, web and shipping, and states that web **`dependsOn`** shipping. Repeat this as required to relate your services together.

   ```
   V:{"uniqueId": "05f337a1-5783-43bb-9323-dfba941455c7", "name": "shipping", "entityTypes": ["service"]}
   V:{"uniqueId": "ae076382-3df9-46cb-97e9-a0342d219efb", "name": "web", "entityTypes": ["service"]}
   E:{"_fromUniqueId":"ae076382-3df9-46cb-97e9-a0342d219efb", "_edgeType":"dependsOn", "_toUniqueId":"05f337a1-5783-43bb-9323-dfba941455c7”}
   ```
9. Load this file into Topology Manager to relate the services. For more information, see Configuring File Observer jobs.

   If your topology changes, then re-create and reload the file as required. A similar process can be followed for non-Kubernetes sources.

High volumes of data can cause Spark workers to run out of memory

If your environment handles high (10+ millions) workloads of alerts or event, your Spark workers can run out of storage (ephemeral storage). If you encounter this issue, restart the affected Spark workers. This issue can also occur if you are running multiple jobs, which can cause the file system to fill, such as with log or JAR files.

Azure observer missing subnet relationship in topology

For the Azure Observer, a subnet can be intermittently missing the relationship with an IP address in the topology for a resource. While the relationship can be intermittently missing, both the subnet and IP address verticies remain available in the topology.

Topologies not visible on Incident Topology page after resource merge

When resources from two observer sources have been merged using the topology merge functionality, the topology is no longer displayed in the Incident view. This known issue affects **only** the Incident view, and the topology is still present in all other views.

Openstack observer missing edge-runsOn connectivity in topology

After running an Openstack observer job, the **`edge-runsOn`** connectivity between **`ComputeHost`** and **`Hypervisor`** elements is not shown in **`Resource Managenent -> Resources`** when it should be.

Topology viewer user interface crashes after the update manager is displayed

The issue is that you cannot use the update manager feature in topology viewer. The solution is to change your topology viewer user preferences to auto render changes on refresh, which prevents the update manager from appearing.

Infrastructure Automation

- Kubernetes permissions are missing for user roles for using Managed services and the Service catalog
- Non-LDAP users cannot access Infrastructure Management
- Red Hat Advanced Cluster Management and IBM Cloud Pak for Multicloud Management core are not supported
- Users are redirected to the Administration panel when logging back into the UI
- Managed services secrets and certificates cannot be customized during installation
- Database fails to reset when error occurs during database creation for Infrastructure Management
- The **`cam-tenant-api`** pod is not in a ready state after installing the iaconfig CR
- Print or export as PDF entire tables does not work as expected
- Infrastructure Management log display in the UI is removed
- Infrastructure Automation Test deploy fails
- On Infrastructure Management appliances, an Ansible playbook deployment fails
- After restoring from a backup, the Managed services deployment fails
- Infrastructure Management fails to save container provider after changing to a new token
- Infrastructure Automation install fails on FIPS enabled Power cluster
- Embedded Terraform feature not supported with FIPS enabled OpenShift Container Platform cluster

Kubernetes permissions are missing for user roles for using Managed services and the Service catalog

If you install Infrastructure Automation, you, or an administrator, must add the required Kubernetes permissions to user roles before your users can begin to access and use Managed services or the Service catalog.

As an administrator, add the following permissions to your use roles:

Table. Required permissions

Role	Required permission for Infrastructure Automation
Automation Administrator	Administer Kubernetes resources
Automation Operator	Manage Kubernetes resources
Automation Developer	Edit Kubernetes resources
Automation Analyst	View kubernetes resources

For more information about how to add permissions to a role, see Managing roles for Infrastructure Automation.

Non-LDAP users cannot access Infrastructure Management

Non-LDAP authenticated users cannot be used with Single Sign-On for Infrastructure Management. If you attempt to use Infrastructure Management with a non-LDAP authenticated user, you can encounter the following error:

While logged in to the Infrastructure Automation UI console with a non-LDAP user, attempting to start Infrastructure Management fails with an error. This is a limitation.

The error states:

```
OpenID Connect Provider error: Error in handling response type.
```

Red Hat Advanced Cluster Management and IBM Cloud Pak for Multicloud Management core are not supported

Installation of Infrastructure Management in IBM Cloud Pak for AIOps does not support Red Hat Advanced Cluster Management and IBM Cloud Pak for Multicloud Management core. You can continue to use the Kubernetes cluster life-cycle templates and services to create a Kubernetes cluster and import the cluster to an existing installation of Red Hat Advanced Cluster Management, if an installation is available. Deploying hybrid applications are also not supported by Infrastructure Automation.

Users are redirected to the Administration panel when logging back into the UI

When you are working within Infrastructure Automation and log out and then log back in, you can be redirected to the Administration panel instead of the Infrastructure Automation home page or other page that you were previously using. If this occurs, you can use the Cloud Pak switcher in the upper right of the UI console to switch to the Infrastructure Automation home page and then return to the page that you were previously using.

Database fails to reset when error occurs during database creation for Infrastructure Management

If you are creating the database for the Infrastructure Management appliance and you encounter an error, such as the database creation failing to complete successfully, you might not be able to continue with your setup without redeploying. For instance, if the creation fails, resetting the database to clean up your database and deployment can also fail. To resolve this issue, you need to redeploy the Infrastructure Management appliance image before reattempting to create the database.

The `cam-tenant-api` pod is not in a ready state after installing the iaconfig CR

After you install Infrastructure Automation, you can encounter an error where the **`cam-tenant-api`** pod displays as running, but not in a ready state. When this error occurs, you can see the following message:

```
[ERROR] init-platform-security - >>>>>>>>>> Failed to configure Platform Security. Will retry in 60 seconds <<<<<<<<<<<<
OperationalError: [object Object]
```

If this error occurs, delete the **`cam-tenant-api`** pod to cause the pod to restart and attempt to enter a ready state.

Print or export as PDF entire tables does not work as expected

If you are using the Firefox browser, and you select **Print or export as PDF** on the **Compute** > **Containers** > **Projects** page to print or export the entire table of data, the print, or export might not work as expected. For instance, some data, such as table rows might be missing. If you encounter this issue, try a different browser for printing or exporting the data.

Infrastructure Management log display in the UI is removed

Log display support on the UI is removed for Infrastructure Management. As an alternative for viewing these logs, use Kubernetes standard methods such as **`oc log`** commands, viewing the output in Red Hat OpenShift Container Platform or Kubernetes, or setting up a log aggregator for your cluster.

You can still see the log tabs (**Collect Logs**, **IA:IM Log**, **Audit Log**, and **Production Log**) on the **Settings** > **Application Settings Diagnostic** page. However, instead of displaying the log information, the following message is displayed: **`Logs for this IA:IM Server are not available for viewing`**.

Infrastructure Automation Test deploy fails

Infrastructure Automation Test deploy from a **Service Overview** page fails to deploy.

On Infrastructure Management appliances, an Ansible playbook deployment fails

When you attempt to deploy an Ansible playbook on an Infrastructure Management appliance through an embedded Ansible deployment, the playbook deployment can fail with the following error:

```
<35.237.119.31> ESTABLISH SSH CONNECTION FOR USER: ubuntu
fatal: [35.237.119.31]: FAILED! => {
"msg": "Unable to create local directories(/home/manageiq/.ansible/cp): [Errno 13] Permission denied: b'/home/manageiq'"
}
```

If you encounter this error, log in to the appliance as the root user and then deploy the playbook again:

1. Run the command:

   ```
   mkdir -p /home/manageiq
   ```

2. Run the command:

   ```
   chown manageiq:manageiq /home/manageiq
   ```

3. Deploy the Ansible playbook again.

After restoring Managed services from a backup, the Managed services deployment fails

After you restore Managed services (**`cam`**) from a backup, the deployment instance fails with a **`socket hang up`** error.

If this error occurs, restart the **`cam-iaas`** pod by running the following command:

```
oc delete pod <cam-iaas-xxxx> -n <namespace>
```

Where **`<namespace>`** is the project (namespace) where Infrastructure Automation is installed, and **`<cam-iaas-xxxx>`** is the name of the **`cam-iaas`** pod to restart.

With this restart, the service deployment can complete successfully.

Infrastructure Management fails to save container provider after changing to a new token

Infrastructure Management fails to save changes to a container provider after updating the access token when the Metrics collection is enabled.

Workaround: After updating and validating the new token in the *Edit provider* dialog box, switch to the **Metrics** tab and validate the existing endpoint. The **Save** button is now enabled.

Infrastructure Automation install fails on FIPS enabled Power cluster

There is an intermittent issue with the installation of standalone Infrastructure Automation on a FIPS enabled Linux on Power (ppc64le) cluster. This occurs when AllNamespace or OwnNamespace mode is used. A problem with the events operator pod causes the installation to fail.

Embedded Terraform feature not supported with FIPS enabled OpenShift Container Platform cluster

The Embedded Terraform feature in Infrastructure Automation is not yet supported in a FIPS enabled OpenShift Container Platform cluster.

UI console

- Tour icon disappears when browsing to another console page while a guided tour is running
- 'Data cannot be displayed': error given for 'Defined Applications' and 'Favorite Applications' tiles on the Home page
- User credential timeout starts in the backend
- Unable to access Identity Providers link in console
- Slow loading pages
- Alert Viewer page shows 400 Error

Tour icon disappears when browsing to another console page while a guided tour is running

When you start a guided tour and navigate away from the page to the IBM Automation *Home* page, the *Tour* icon might not display on the toolbar. This behavior can occur when an IBM Cloud Pak for AIOps tour is still running. Only one guided tour can run at a time. To resolve this issue, return to an IBM Cloud Pak for AIOps page, click on the *Tour* icon and close a tour. When you return to the IBM Automation *Home* page, the *Tour* icon reappears.

'Data cannot be displayed': error given for 'Defined Applications' and 'Favorite Applications' tiles on the Home page

On opening the Console home page neither 'Defined Applications' nor 'Favourite Applications' is listed in their tiles. However, they do exist as they can be viewed under the 'Resource Management' section. The fix for this is to restart the aiops-base-ui pods.

User credential timeout starts in the backend

The first indications of a user credential timeout might be backend failures. For example, failure to load incident, alert, or policy lists. To resolve this issue if it occurs, log out and log back in again, or wait for the frontend logout to occur.

Unable to access Identity Providers link in console

You might notice that you are unable to access the **Identity Providers** link located in the UI console. You might see an error such as *HTTP ERROR 431*. If this issue occurs, configure the LDAP connection. For more information, see Identity Management (IM).

Slow loading pages

If you are experiencing slow loading of Cloud Pak for AIOps pages, it might be because the server TLS certificate is not trusted by your browser. Some browsers (for example, Microsoft Edge and Google Chrome) prevent caching of resources when the server's certificate is untrusted. This means all static resources associated with the page are fully reloaded on every refresh, significantly slowing down page loads.

To resolve the issue, a certificate signed by a certificate authority that is trusted by your client devices should be used. Using a custom certificate is described in the Using a custom certificate page. This may be a certificate signed by a well known certificate authority, or an internal certificate authority pre-configured on your client devices.

Alert Viewer page shows 400 Error

You might notice that you are unable to access the Alert Viewer page. You might see a **400** error. This error is caused when the cookies for the IBM Cloud Pak for AIOps domain in your browser get too large for the data layer service to consume.

To resolve this issue, clear the cookies in your browser and then reload the page.

AI Model management and training

- Log parsing assigns messages to catch-all template instead of generating expected template
- Elasticsearch record count does not match record count published to Kafka topic
- Log anomaly detection EXPIRY_SECONDS environment variable not retained after an upgrade
- Log anomalies are not detected by natural language log anomaly detection algorithm
- Metric anomaly detection training does not run on schedule
- In Change risk training, Precheck indicates "Good data" but models fail to create
- Alerts for the Log Anomaly - Golden Signals algorithm are not generated when inference log data contains name and value pairs
- Counts against template patterns are not updated in the training UI
- Similar tickets training in IBM Cloud Pak for AIOps on Linux
- Change risk is unable to load the models
- **`aiops-lad-flink-taskmanager-xxx`** in CrashLoopBackOff status

Log parsing assigns messages to catch-all template instead of generating expected template

If you use catch-all templates for mapping uncategorized messages during AI model training, you can encounter an issue where the log parsing assigns messages for an error to the catch-all templates instead of generating an expected template for that error. If this issue occurs, you might not see expected anomalies.

If you suspect this issue is occurring and you do not see expected anomalies, complete the following steps to manually verify your training templates, and remove any catch-all templates that incorrectly generated.

1. Retrieve the normalized logs from your logtrain indices.
2. Identify the logs that are error logs. Review those logs to determine the template mappings.
3. Retrieve the identified templates from Elasticsearch.
4. Use the error log contents and the template ID from the retrieved normalized logs to identify the template string within the retrieved templates.
5. If the template string is comprised entirely of parameters, or a single word and parameters, the template might be a catch-all template. For example, the following string is an example of a catch-all template:

   ```
   <>to <><><><><>
   <> <> <> <>-<>-<> <> <> <> <> <> <> <> <> <> <>
   ```

6. Manually delete any catch-all templates.

Elasticsearch record count does not match record count published to Kafka topic

When you push a large training file (for example 60 M records, such as logs or events) to Kafka through your configured integration, the number of records that are ingested and displayed on Elasticsearch might not match. Elasticsearch record count might be lower than Kafka count due to deduplication. If you encounter this issue, split large files into smaller batches and send them individually to Kafka (for example, 5 M records each). When you are pushing a batch, ensure that you wait for an ingest to complete and the associated records display on Elasticsearch before you push the next batch of records.

Log anomaly detection EXPIRY_SECONDS environment variable not retained after an upgrade

If you set a value for the *EXPIRY_SECONDS* environment variable and upgrade, the environment variable is not retained after the upgrade.

After the upgrade is completed, set the environment variable again. For more information about setting the variable, see Configuring expiry time for log anomaly detection alerts.

Log anomalies are not detected by natural language log anomaly detection algorithm

In some cases a model that has been trained successfully is unable to detect certain log anomalies. The quality of the model is independent of whether it trained successfully, and model quality tends to improve as more training data is available. If the model is not detecting anomalies in your logs, consider training the model again but using additional days of training data to improve the model quality.

Metric anomaly detection training does not run on schedule

If you have metric anomaly detection training scheduled to run, such as daily, you can encounter an issue where the training does not run as scheduled. If the training job does not run on schedule, log in to the IBM Cloud Pak for AIOps console and click the *Metric anomaly detection* algorithm tile and then *Train models*.

In Change risk training, Precheck indicates “Good data” but models fail to create

On rare occasions, a Change risk model fails to create, even though *Precheck data* indicates that the data is good. This failure is caused by an insufficient number of problematic change risk tickets being available to create a good model. This problem resolves itself when enough tickets become available for the model. (For more information, see Closed change ticket count requirements).

To confirm that insufficient problem tickets is causing the failure, view the Change risk logs on the training pods.

To retrieve the pod:

```
oc get pod | grep training-cr
```

View the logs for training Change risk models.

```
oc logs <pod-name> # Ex: training-cr-1b5ef57f-9053-4037-95ca-c1e8b8748fc5
```

Check whether the log contains the following

```
size of the problematic (aka labels) tickets is insufficient
```

If confirmed, ensure that enough problematic change tickets are available before training the model again.

Alerts for the Log Anomaly - Golden Signals algorithm are not generated when inference log data contains name and value pairs

In IBM Cloud Pak for AIOps 4.8.0, alerts might not be generated for the Log Anomaly - Golden Signals algorithm when inference log data contains name and value pairs. These pairs are tokens with the **`key=value`** pattern. They might prevent anomalies from being matched to their respective templates.

For example, training generates the following log template:

```
<> exe="/usr/bin/dbus-daemon" sauid=UNKNOWN_VAR hostname=? addr=? terminal=?'
```

Then, during inference, incoming log data is matched against the template from training. If the incoming log data contains tokens with the **`key=value`** pattern like in the following example, the logs are classified as unmatched.

```
[3557470.922719]  exe=\"/usr/bin/dbus-daemon\" sauid=103 hostname=? addr=? terminal=?'
[3557971.107893]  exe=\"/usr/bin/dbus-daemon\" sauid=103 hostname=? addr=? terminal=?'
```

Alerts from this set of logs are not displayed.

Counts against template patterns are not updated in the training UI

When the log anomaly detection - golden signals algorithm generates alerts in IBM Cloud Pak for AIOps 4.8.0, the counts against those template patterns are not updated in the training UI table. Enable historic alert storing in Elasticsearch to access alert counts.

Workaround: Enable the components by editing the installation. Use the following commands to access the installation through the command line. Replace **`<installation-name>`** with the name of the installation:

```
oc get installation
oc edit installation <installation-name>
```

Or access the installation with the Red Hat® OpenShift® console. Go to **Operators** > **Installed Operators** > **IBM Cloud Pak for AIOps** > **IBM Cloud Pak for AIOps** and edit the YAML file for **`aiops-installation`**.

After you access the installation, edit it to include the following values:

```
spec:
  automationFoundation: {}
  license:
    accept: true
  pakModules:
    - config:
```

```
    - name: ir-core-operator   # Find the config item with this name, or add this item if it does not exist
      spec:
        issueresolutioncore:
          customSizing:
            deployments:
            - name: datarouting
              replicas: 1   # Use 3 for large deployment
            - name: esarchiving
              replicas: 1
    enabled: true
    name: applicationManager  # Find the pakModules item with this name, or add this item if it does not exist
```

After the components are enabled, new alerts are stored to Elasticsearch indices, and the alert counts for subsequent alerts are updated correctly in the training UI table.

Similar tickets training in IBM Cloud Pak for AIOps on Linux

Similar tickets training is not available in IBM Cloud Pak for AIOps on Linux. You can manually add tickets from your ticketing integrations in the incident overview.

Change risk is unable to load the models

Change risk is unable to detect the usage of OpenSearch analytical engine. The algorithm relies on reading from a mounted file, but in this case, the file was not mounted correctly. As a result, change risk is unable to function properly and cannot write data to the database. Use the following command to add the missing **volume** and **volumeMounts** as a workaround:

```
CR_DEPLOY=$(oc get deployments | grep change-risk | awk '{print $1}')
# get es secret name
oc get AIOpsEdge aiopsedge -o jsonpath='{.spec.elasticsearchSecret}'
# copy that secret name, something like `aiops-installation-es-admin-user-connection-secret`,
# and run the following oc patch command by replacing the ES_SECRET_NAME
oc patch deployment $CR_DEPLOY --type=json -p '[
  {
    "op": "add",
    "path": "/spec/template/spec/volumes/-",
    "value": {
      "name": "elastic-volume",
      "secret": {
        "secretName": "ES_SECRET_NAME",
        "defaultMode": 420
      }
    }
  },
  {
    "op": "add",
    "path": "/spec/template/spec/containers/0/volumeMounts/-",
    "value": {
      "name": "elastic-volume",
      "mountPath": "/etc/elastic"
    }
  }
]'
```

`aiops-lad-flink-taskmanager-xxx` in CrashLoopBackOff status

You might notice that **aiops-lad-flink-taskmanager-xxx** pod is in **CrashLoopBackOff** status approximately 60 days after the pod deployment. You might notice the following errors in pod logs:

```
2025-02-10 15:34:12,183 INFO  org.apache.flink.runtime.taskexecutor.DefaultJobLeaderService [] - Start job leader
service.
2025-02-10 15:34:12,184 INFO  org.apache.flink.runtime.filecache.FileCache                  [] - User file cache uses
directory /tmp/flink-dist-cache-40ec62bb-f436-4ecf-ae5d-2b1a2e5a4d61
2025-02-10 15:34:12,188 INFO  org.apache.flink.runtime.taskexecutor.TaskExecutor           [] - Connecting to
ResourceManager pekko.ssl.tcp://flink@10.255.255.155:6123/user/rpc/resourcemanager_4(b243c492b5fcd94aecc216000b7946c5).
2025-02-10 15:34:12,346 INFO  org.apache.flink.runtime.taskexecutor.TaskExecutor           [] - Could not resolve
ResourceManager address pekko.ssl.tcp://flink@10.254.43.255:6123/user/rpc/resourcemanager_4, retrying in 10000 ms: Could
not connect to rpc endpoint under address pekko.ssl.tcp://flink@10.254.43.155:6123/user/rpc/resourcemanager_4.
```

If the issue is related to certificate rotation, a possible workaround might be manually rotating the certificates or restarting the pods.

ChatOps

- In Slack, a ChatOps communication to IBM Cloud Pak for AIOps times out without establishing a connection
- In a Microsoft Teams ChatOps, the attach template logs feature does not work
- Incidents cannot be reopened or restored in ChatOps
- No Recommended runbooks found in incident overview
- No incident content viewable in Microsoft Teams on mobile devices
- During a ChatOps secure tunnel creation an 'installation failed' message displays

In Slack, a ChatOps communication to IBM Cloud Pak for AIOps times out without establishing a connection

When sending a ChatOps communication from Slack to IBM Cloud Pak for AIOps, a known intermittent issue can occur. The communication between Slack and IBM Cloud Pak for AIOps can time out after 3 seconds of no response. A potential solution is to reconfigure your connection in the connection onboarding. Ensure that your Slack Bot can access your IBM Cloud Pak for AIOps instance in a prompt fashion. A more permanent and robust solution to this issue is being devised.

In a Microsoft Teams ChatOps, the attach template logs feature does not work

If you have a Microsoft Teams ChatOps, clicking the **Attach template logs** button does not work and the logs are not sent to your Microsoft Teams channel for review. As an alternative, use the **Preview logs** button to view the template logs.

Incidents cannot be reopened or restored in ChatOps

When an incident is closed it is archived and can no longer be modified. If a new alert occurs that is related to the archived incident, a new incident is created instead of reopening the archived incident.

No Recommended runbooks found in incident overview

If a runbook recommends to remediate an incident is deleted from the runbook Library, it does not remove the **Recommended runbooks** link in a ChatOps notification. This can result in the ChatOps runbook section linking out to an empty runbooks page in the incident overview.

No incident content viewable in Microsoft Teams on mobile devices

On mobile devices, when viewed in Microsoft Teams, incidents can appear with no viewable data. Where this happens, switch to using a computer to see the full incident data.

During a ChatOps secure tunnel creation an 'installation failed' message displays

When you create a ChatOps integration and it fails, wait for a few minutes to see if the installation retries, and if it does not simply create the integration again.

Incidents and alerts

- Active incident count is wrong on the Resource management page
- "An error occurred while fetching data from the server"
- Alerts tab shows "An unknown error occurred" error when all alerts are closed
- Closed incidents are missing details and displaying a critical error
- Metric anomaly chart unexpectedly changes from zoom view to normal view
- Unable to add metric anomaly in Related alerts to chart
- Limitation of preview text for default recommended action
- Metric search page chart lines are disjointed
- Some alerts not cleared even with a resolution event
- Alert views are unusable without ID and SUMMARY columns
- Filter on short ID in the incident table doesn't work

Active incident count is wrong on the Resource management page

The Resource management page displays a number of incidents in the Active incidents column instead of displaying one incident with a number of alerts. The Application viewer displays the correct information, however.

This error can occur when related groups or applications are erroneously linked to the incident count.

Workaround: Verify the correct number of incidents and alerts on the Application viewer.

"An error occurred while fetching data from the server"

When viewing the Incidents UI or when creating a policy to assign runbooks to alerts, you might see the message "An error occurred while fetching data from the server". Or in the Alert Viewer, you might see "An unknown error occurred". If you encounter these error messages, complete the following steps to delete the `aiops-ir-ui-api-graphql` pod. The pod is then automatically re-created, which should resolve the error.

1. Log in to your cluster by running the oc login command.

   ```
   oc login -u kubeadmin -p <password>
   ```

2. Delete the aiops-ir-ui-api-graphql pod.

   ```
   oc delete pod -l component=aiops-ir-ui-api-graphql -n <cp4aiops_namespace>
   ```

3. Wait for the pod to restart.

Alerts tab shows "An unknown error occurred" error when all alerts are closed

If you are viewing a closed incident that has all associated alerts resolved, you can encounter an error when you view the Alerts tab. This "An unknown error occurred" error displays when there are no associated alerts. You can ignore this error message as the incident and alerts are resolved and closed.

Same runbook status for multiple alerts in an incident

If more than one alert meets a runbook policy's conditions, the same runbook can be assigned to multiple alerts in an incident. From the incident overview page, you can select an alert and run an associated runbook. The runbook **Status** of the selected alert will be updated on the UI. However, the runbook status of other alerts in the incident might be updated with the same status. This is a known issue.

Closed incidents are missing details and displaying a critical error

Incidents with status of "Closed" are missing topology information on the incident **Overview** tab. The associated alerts of the closed incidents are also missing from **Alerts** tab. The following critical error is displayed on the **Topology** tab for closed incidents: "No resource exists with the specified identifier and time point".

Metric anomaly chart unexpectedly changes from zoom view to normal view

This can occur when a related alert is selected and added to a chart you are zoomed in on. The chart resets to normal view. To resolve, zoom in again after related alert is added to chart.

Unable to add metric anomaly in Related alerts to chart

In some cases, when you click the checkbox in the *Related alerts*, it does not add the related anomaly to the metric anomaly chart.

Limitation of preview text for default recommended action

When an alert is generated from any default log anomaly detection models, the preview of a recommended action might contain partial texts and does not reflect the full view of the recommended action. The first 4000 characters are extracted from the original resolution or action document webpage where possible, from which nonreadable texts such as URLs are excluded to form the content of the preview text.

Metric search page chart lines are disjointed

In the Metric search page chart, the normalised forecast line is disjointed from the baseline data line. This is because the forecast data is normalised independently from the baseline data. Although the lines might not match up, the values shown in the tooltips are correct.

Some alerts not cleared even with a resolution event

In scenarios where large amounts of historical event data are ingested into the system, it's possible that problems and resolutions can be processed out of order, sometimes resulting in alerts not clearing as expected. To avoid this issue, try ingesting smaller batches of event data into the system.

Alert views are unusable without ID and SUMMARY columns

When creating views in the Alert Viewer, you must include the ID and SUMMARY columns in the view. Otherwise, the view will be unusable and can only be deleted by using the API.

Filter on short ID in the incident table doesn't work

You cannot use the short **ID** from the incident table as a filter condition under **Other properties**. Instead, use the full incident `"id"` which can be found in the incident details side panel > raw data format.

Policies

- Condition **Value** field changes `String:alert` to `Value of:alert`
- Breadcrumb navigation missing in policy editor
- Condition **Matches** field for numeric **Operator** selections
- **Last run** time and **Matched** count is updated in policies other than the trigger policy
- Double scroll bars on browser window
- Policy processing failing due to long policy conditions
- No ServiceNow ticket created by incident creation policy
- Datarouting pods can fail and need to be restarted
- Using default values in automatically run runbooks not working
- Netcool alert not suppressed when X in Y suppression policy conditions are met
- Cloud Pak for AIOps Impact policy fails to run when 'No input' is selected
- Policy triggered based on 'incident-updated' runs more times than expected
- Parameter mapping issues in IBM Tivoli Netcool/Impact policies
- Can't use alert.details.name with "any of" in a policy condition
- Policy is triggered against alerts that don't match the condition
- WebSphere resolution action recommendation policy showing a failed status

Condition Values field changes "`String:`" to "`Value of:`"

For example, in a policy condition if the string "`alert.id`" is typed in the **Values** field, and then "`String:alert.id`" is selected, it is changed to "`Value of:alert.id`".

To prevent this, avoid a string that exactly matches the keyword. In this example, use the following condition instead:

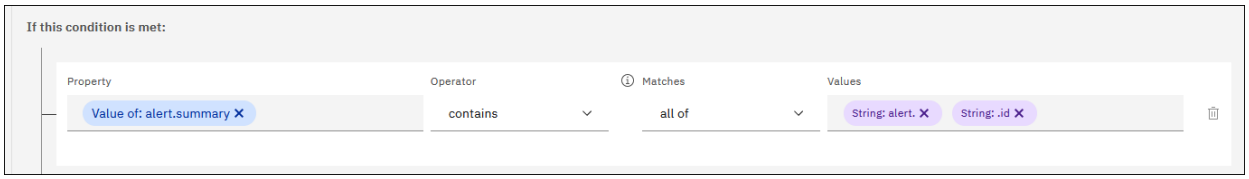

Figure. Policy condition

Note: This example is not an exact match of the string **alert.id**. This workaround finds all summaries containing **alert.** and **.id**.

Breadcrumb navigation missing in policy editor

In some cases where a policy name is long, the breadcrumb navigation in the top left of the policy edit session can be abbreviated. Clicking the breadcrumb still returns you to the Policy UI.

Condition "Matches" field for numeric "Operator" selections

When using a numeric **Operator** in a policy condition set (for example, **greater than**, **less than**, **greater or equal**) all options can be selected under **Matches**. However, always select **Only** for use with a numeric operator.

"Last run" time and "Matched" count updated in policies other than the trigger policy

In a case where an alert meets the incident-creation conditions of multiple policies, only one incident is created. However, all policies that proposed an incident, and the system incident creation policy has the same **Last run** times on the **Policies** hub. Each of these policies also increment their **Matched** counts by 1 in the **Details** tab of the side panel.

Double scroll bars on browser window

An extra scroll bar might appear on the right side of the browser window.

Policy processing failing due to long policy conditions

Policies that have conditions that are long (100,000+ characters) can cause policy processing to fail, resulting in no alerts or incidents being created. Failure can occur when temporal correlation training generates groups containing many alerts, and those alerts have long resource or type fields.

If this problem occurs, such policies should be disabled from the automation policy UI. Identify the policies by

1. Filtering for analytics policies.
2. Sorting by last run time (to identify those that have been processed recently and are likely triggering the problem).
3. Viewing the specification for each to see whether any have a long condition.

Any policies that show up by implementing these steps should be disabled.

No ServiceNow ticket created by incident creation policy

An alert meets the incident-creation conditions of a policy, but no ServiceNow ticket is associated to the incident.

To avoid this, complete the following steps under **actions** in the policy editor:

1. Click **Assign and notify**.
2. Select **In an existing channel**.

Datarouting pods can fail and need to be restarted

After installation, data for display in the UI, such as in the policy list, can be missing or stale.

If this issue occurs, restart the datarouting pods. You can identify these pods by using the following command:

```
oc get pods | grep datarouting.
```

Using default values in automatically run runbooks not working

This problem can occur by selecting a **Default parameter value** when creating a policy to assign runbooks to alerts. The `useDefault` value is not passed during automatic execution but is passed during manual execution.

You can execute the runbook manually from the **Runbooks** page.

Netcool alert not suppressed when X in Y suppression policy conditions are met

If you create an X in Y suppression policy that matches an alert originating from an IBM Tivoli Netcool/OMNIbus environment, the alert will not be suppressed.

Cloud Pak for AIOps Impact policy fails to run when 'No input' is selected

When enabling a Cloud Pak for AIOps Impact policy to Invoke an IBM Tivoli Netcool/Impact policy, the policy fails to run when **No input** is selected under the policy parameter mapping options. To avoid this, select one of the other mapping options. For example, select **Send the full alert**.

Policy triggered based on 'incident-updated' runs more times than expected

If you have a Cloud Pak for AIOps policy that is triggered based on incident-updated, in some cases, the policy might run more times than expected. This is because not all updates can always be processed atomically and the incident might then be updated multiple times. In turn, the incident-updated trigger will be activated more than once.

Parameter mapping issues in Netcool/Impact policies

The following known issues have been obeserved when creating policies to invoke IBM Tivoli Netcool/Impact:

- The policy cannot be created with a parameter mapping option of **No Input** selected. The policy is instead saved with a **Send the full alert** mapping.
- A Netcool/Impact policy cannot be edited to change the parameter mapping option. The change is not persisted. To workaround this problem, create a new Netcool/Impact policy with the new parameter mapping option and disable the current policy.
- When a Netcool/Impact policy is created with a trigger entity of **Incident** and a parameter mapping option of **Send the full incident**, the mapping changes to the **Customize** option if the policy is edited.

Can't use alert.details.name with "any of" in a policy condition

When alert.details is selected in the property field or the value field, the **Details name** field is an optional input where you can minimize the scope to a singular key within the alert's details. However, **Details name** cannot be used in a policy condition with the Matches option of "any of".

Policy is triggered against alerts that don't match the condition

This can occur when you try to compare a NULL value in the policy condition. The policy is triggered because you can have a condition of NULL = NULL matched when the parameters referenced in the policy are not present.

To avoid this problem, you can ensure that the alert property is not equal to NULL in the condition set. For example, see the following policy conditions for **alert.details.name**:

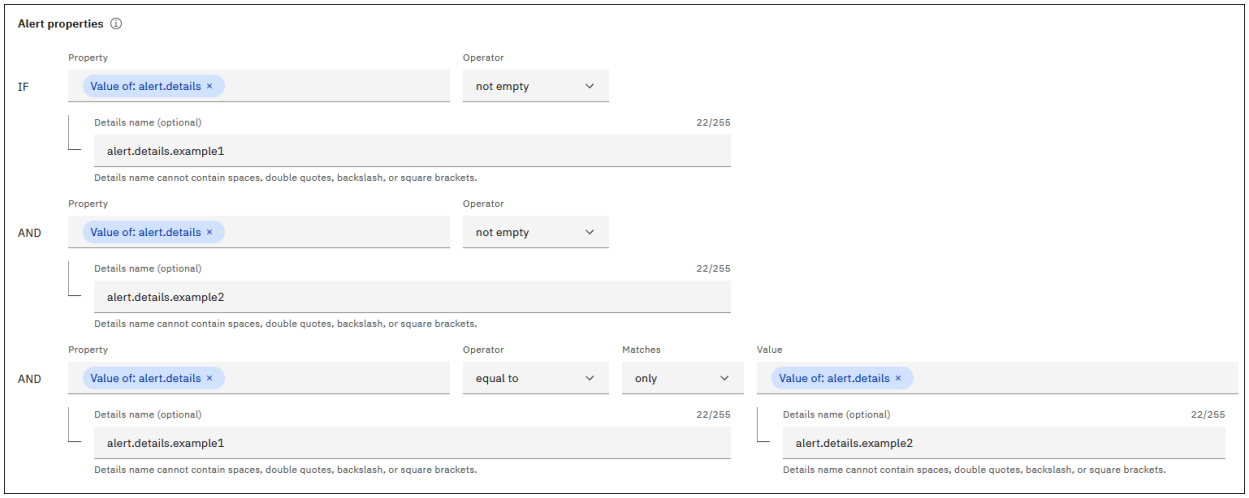

Figure. Policy conditions to avoid comparing a NULL value

WebSphere resolution action recommendation policy showing a failed status

The preset policy "WebSphere resolution action recommendation policy" might initially show a failed status in the policy table. If you encounter this, the policy status should self correct after a period of time.

Secure Tunnel

- Secure Tunnel connector is not running after restart with Podman

Secure Tunnel connector is not running after a restart with Podman

This issue can occur when you install the Secure Tunnel connector to a host machine on which Podman is installed. When the host machine is rebooted and the Secure Tunnel connector is checked by using the **`podman ps -a`** command, the Secure Tunnel connector container does not display **`running`** status.

If this issue occurs, the **`podman-restart`** service must be activated by using the **`systemctl`** command:

```
systemctl start podman-restart
systemctl enable podman-restart
```

After entering the command, check **`podman-restart`** worked by using the following command:

```
systemctl status podman-restart
```

If the Connector is still not running, try restarting the host machine.

Runbook Automation

- When **`alert.suppressed`** value is used, runbook does not automatically run

When `alert.suppressed` value is used, runbook does not automatically run

Normally, you can select a runbook and configure it to run automatically: when an alert is converted to an incident, the runbook is assigned and runs automatically. However, if the parameter value **`alert.suppressed`** is used, the runbook does not run automatically as it reads this as a Boolean value rather than a string value. Therefore, it is necessary to manually run the runbook.

AIOps Insights

- Number of Incidents reported in *Noise reduction* chart is inconsistent with number of Alerts and Events
- AIOps Insights dashboard fails to load even when data is available
- Events not showing up on *Noise reduction* chart

Number of Incidents reported in Noise reduction chart is inconsistent with number of Alerts and Events

In the **AIOps Insights** dashboard, the *Noise reduction* chart normally indicates the number of alerts, events, and incidents reported over a specific time period. However, the inclusion of historical data – containing longstanding, unresolved alerts – can result in a skewering of the data that is presented on the chart: the number of incidents that are presented can outnumber the number of alerts and events. Normally, this number is less than either – alerts reduce to a smaller number of events and events reduce to a smaller number of incidents.

The anomalous incident number happens because the reduction time frame covers alerts and events that are generated in the time period selected (for example, 7 Days). However, the incidents are generated from all outstanding alerts, including alerts that are not resolved, historically: alerts that occurred before the selected time period. So, in these circumstances, while the number of alerts and events is correct, the number of incidents is not.

AIOps Insights dashboard fails to load even when data is available

Large amounts of data can cause the dashboard to fail to load or time out with the message **`Error – Metrics unavailable`** displayed for each chart. The problem is a scaling issue. The **AIOps Insights** dashboard is not yet developed enough to handle huge amounts of data. A possible workaround is to increase resources for **`insights-api`** and **`elasticsearch`** pods. However, this approach might not be successful.

Events not showing up on *Noise reduction* chart

The charts in AIOps Insights cover a timeline no greater than 30 days. The dashboard reads the **`firstOccurenceTime`** value from only within that period. If an alert was created outside of that timeline, and deduplicated, it is not added to the **`eventCount`** in the AIOps Insights Noise reduction chart. In this scenario, the **`eventCount`** for the alert increments in IBM Cloud Pak for AIOps, but not in the *Events* segment of the Noise reduction chart.

Ticketing

- IBM Change Risk Assessment tab in ServiceNow not displaying change risk assessment details
- Select incident state transitions are not permitted in ServiceNow
- Data synchronization in ServiceNow is not working consistently

IBM Change Risk Assessment tab in ServiceNow not displaying change risk assessment details

In a proactive ChatOps channel, you can click the Change request ticket URL to view its details in a ServiceNow instance. However, in some cases in version 4.1.1 of the ServiceNow App, details might not be displayed in the **IBM Change Risk Assessment** tab.

To avoid this issue, update the ServiceNow App to version 4.2.1 or higher.

Select incident state transitions are not permitted in ServiceNow

Cloud Pak for AIOps enforces certain state transitions for its incidents. To synchronize incident data with ServiceNow, the following state transition restrictions must be enforced in ServiceNow as well:

- New -> On Hold
- On Hold -> New
- On Hold -> Resolved
- On Hold -> Closed
- On Hold -> Cancelled

An incident must be set to In Progress before it can go On Hold. An On Hold incident can only transition to In Progress.

Data synchronization in ServiceNow is not working consistently

If you have a ServiceNow integration, you can encounter an issue where updates to records in ServiceNow are not displaying for those incidents and alerts within Cloud Pak for AIOps.

To address this issue, run the following command from the namespace where Cloud Pak for AIOps is installed:

```
oc set env deployment/$(oc get deploy -l app.kubernetes.io/component=chatops-orchestrator -o
jsonpath='{.items[*].metadata.name }') GUNICORN_TOTAL_WORKERS=1
```

If this issue occurs, review the following tasks to ensure your integration and processes are set up correctly:

- Setting up the ServiceNow instance by configuring the ServiceNow App.
- Creating and configuring the ServiceNow integration.
- Configuring a policy to create ServiceNow tickets.

Deprecated and removed functions

Frequent updates to the product and changes in technology require that some function is deprecated or removed from support. See the following sections for definitions of stabilized, deprecated, and removed function and tables that identify items from these categories.

Deprecated functions

A *deprecated* item is supported, but no longer recommended for use and might become obsolete. Consider the alternative actions in the *Recommended action* and details that are provided in the following table:

Table. Deprecated function

Product or category	Affected item	Status	Version	Recommended action	More details and links
Microsoft System Center Virtual Machine Manager (SCVMM)	Infrastructure Automation - Infrastructure Management	Deprecated	3.6.0	No change in version 3.6.0	Microsoft System Center Virtual Machine Manager (SCVMM) might be removed as a supported platform for Infrastructure Management in a future release.
Advanced Content Runtime	Infrastructure Automation - Managed services	Deprecated	3.3.0	No change in version 3.6.0	Advanced Content Runtime might be removed in a future release. If removed from Infrastructure Management, you will need to import Advanced Content Runtime templates yourself.

Product or category	Affected item	Status	Version	Recommended action	More details and links
PostgreSQL 10 (Infrastructure Automation)	Infrastructure Automation - Infrastructure Management	Deprecated	3.6.0	Upgrade to PostgreSQL 13	• If you need to upgrade for appliances, see Migrating IBM Red Hat CloudForms and IBM Cloud Pak for Multicloud Management appliances to Infrastructure Automation • If need to upgrade for a podified installation, see Upgrading PostgreSQL for a podified Infrastructure Management installation.
GitOps	IBM Cloud Pak for AIOps	Deprecated	4.4.0	No change in version 4.4.0	Support for using the IBM GitOps repository method to install IBM Cloud Pak for AIOps is deprecated and will be removed in a future release.
Natural language log anomaly detection algorithm	IBM Cloud Pak for AIOps	Deprecated	4.4.0	Use log anomaly detection - golden signals	As a replacement, use log anomaly detection - golden signals.
Statistical baseline log anomaly detection algorithm	IBM Cloud Pak for AIOps	Deprecated	4.4.0	Use log anomaly detection - golden signals	As a replacement, use log anomaly detection - golden signals.

Removed functions

A *removed* item is typically function that was deprecated in previous releases and is no longer available in the product. You must use alternative features as a replacement for the removed function. Consider the alternative actions in the *Replacement* and details that are provided in the following table:

Table. Removed function

Product or category	Affected item	Version	Replacement	More details and links
GitOps	IBM Cloud Pak for AIOps	4.5.0	Use one of the other options in Installing.	Support for using the IBM GitOps repository method to install IBM Cloud Pak for AIOps is removed.
Kubernetes integration (connector) and documentation	IBM Cloud Pak for AIOps	4.1.0	Configure a Kubernetes observer job as a replacement.	
VMWare integration (connector) and documentation	IBM Cloud Pak for AIOps	4.1.0	Configure a VMware NSX observer job or VMware vCenter observer job as a replacement.	
Red Hat® OpenShift® Container Platform 4.8	IBM Cloud Pak for AIOps	3.7.1	Use Red Hat OpenShift Container Platform 4.10 or 4.12	Supported Red Hat OpenShift Container Platform versions
Red Hat OpenShift Container Platform 4.10	IBM Cloud Pak for AIOps	4.2.0	Use Red Hat OpenShift Container Platform 4.12	Supported Red Hat OpenShift Container Platform versions
Red Hat OpenShift Container Platform 4.11	IBM Cloud Pak for AIOps	4.4.1	Use Red Hat OpenShift Container Platform 4.12, 4.13, or 4.14	Supported Red Hat OpenShift Container Platform versions
Red Hat OpenShift Container Platform 4.12	IBM Cloud Pak for AIOps	4.7.1	Use Red Hat OpenShift Container Platform 4.14, 4.15, 4.16, or 4.17	Supported Red Hat OpenShift Container Platform versions
Red Hat OpenShift Container Platform 4.13	IBM Cloud Pak for AIOps	4.7.1	Use Red Hat OpenShift Container Platform 4.14, 4.15, 4.16, or 4.17	Supported Red Hat OpenShift Container Platform versions
GitHub integration (connector)	Integrations	3.6.0	--	--
IBM Cloud Pak CLI (`cloudctl`)	IBM Cloud Pak for AIOps, for offline install and upgrade	3.6.0	Use the `ibm-pak` plugin for the OpenShift `oc` CLI tool instead of `cloudctl` commands.	Install and upgrade instructions for offline deployments now use `oc ibm-pak` commands instead of `cloudctl` commands.
Event Manager Gateway	IBM Cloud Pak for AIOps and IBM Netcool Operations Insight deployment scenario	3.6.0	Use the Netcool integration (connector)	Installing IBM Cloud Pak for AIOps with IBM Netcool Operations Insight or on-premises Netcool Operations Insight in version 3.6.0
Log display support	Infrastructure Management	3.6.0	--	Log display support on the UI is removed
Terraform 0.11.15	Infrastructure Automation - Managed services	3.6.0	--	You might be able to still use Terraform 0.11.15, but you will need to upload the required engine, providers, or content yourself.
Terraform 0.12.31	Infrastructure Automation - Managed services	Deprecated	3.7.0	No change in version 3.7.0
Terraform 0.13.7	Infrastructure Automation - Managed services	Deprecated	3.7.0	No change in version 3.7.0

Product or category	Affected item	Version	Replacement	More details and links
Terraform 0.14.11	Infrastructure Automation - Managed services	Deprecated	3.7.0	No change in version 3.7.0
Terraform 1.1.9	Infrastructure Automation - Managed services	Deprecated	3.7.0	No change in version 3.7.0
New installs - certificates provided by IBM Automation foundation	IBM Cloud Pak for AIOps and Infrastructure Automation	4.1.0	Red Hat OpenShift Container Platform cluster certificates or user created custom certificates	What's new - install and upgrade in version 4.1.0
User interface using a different storage class	IBM Cloud Pak for AIOps	4.1.0		
Infrastructure Automation	Configure Network option from appliance_console tool	4.5.0	Use the command line to configure networking	To configure networking with the command line, **nmtui** is available for a text user interface or **nmcli** for scripting. Networking can also be configured through the *Cockpit Web interface* (https://:9090) as a root user.

frequently asked questions (FAQ)

Review the following frequently asked questions for IBM Cloud Pak for AIOps

About IBM Cloud Pak for AIOps

- What is IBM Cloud Pak for AIOps?
- What are the Capabilities of IBM Cloud Pak for AIOps?
- How can Cloud Pak for AIOps assist an Ops engineer?
- How can Cloud Pak for AIOps assist a Line of Business (LOB) engineer/CTO?
- How can Cloud Pak for AIOps assist a Site Reliability Engineer (SRE)?
- What are the benefits of using IBM Cloud Pak for AIOps?

What is IBM Cloud Pak for AIOps?

IBM Cloud Pak for AIOps is an AIOps platform developed by IBM to help organizations simplify complex IT operations and improve efficiency. The platform utilizes advanced, explainable AI to assess, diagnose, and resolve incidents across mission-critical workloads, easing the path to adopting AI for ITOps and decreasing operational costs. By automating routine tasks and providing advanced diagnostic capabilities, Cloud Pak for AIOps enables organizations to save time and resources, focusing on innovation and strategic initiatives. Its explainable AI approach ensures transparency and trust in the decision-making process, making it an ideal solution for high-stakes situations requiring rapid and accurate decision-making. To get a full overview of AIOps go to Overview.

What are the Capabilities of IBM Cloud Pak for AIOps?

Cloud Pak for AIOps capabilities include:

- Cross-domain data ingestion and integration
- Topology generation
- Event correlation and analytics
- Incident and pattern recognition
- Augmented remediation

How can Cloud Pak for AIOps assist an Ops engineer?

An Ops engineer can leverage the powerful AI and analytics capabilities of the Cloud Pak for rapid incident remediation, augmented with tailored context, and recommended actions. Use cases include incident remediation, and service assurance.

How can Cloud Pak for AIOps assist an Ops Manager?

Operations Managers can more effectively understand the types of incidents that most frequently occur and create policies and runbooks to improve their operations responsiveness and maximize uptime. Use cases include policy administration, and incident triage management.

How can Cloud Pak for AIOps assist a Line of Business (LOB) engineer/CTO?

Line of Business Managers and CTO's can take advantage of the AIOps Insights Dashboard to understand how their applications are performing over time and the benefits their AIOps Platform is providing to the business. A use case is application or service reporting.

How can Cloud Pak for AIOps assist a Site Reliability Engineer (SRE)?

A SRE can ensure that their applications are running smoothly, even when making changes or upgrades with Change Risk Assessment and the Topology timeline view. Use cases include incident resolution and change risk mitigation.

What are the benefits of using IBM Cloud Pak for AIOps?

The main benefit is the automation of every aspect of incident resolution, including:

- **Diagnose problems faster** and correlate a vast amount of unstructured and structured data in real time
- **Automate with confidence** and empower teams to automate tasks with transparent AI decision-making
- **Gain insights where you work** and keep teams focused, incorporating insights and recommendations into existing workflows to make informed decisions
- **Build and manages securely** – build policy at the microservice level and automate across application components

- **Integrate seamlessly** with monitoring tools and pretrained AI models to gain new insights

About the documentation

- Where can I learn about new or changed features for each release?
- Where can I access known issues for each release?
- Where can I find terms and definitions for IBM Cloud Pak for AIOps?
- Where can I find out about deprecated and removed functions?

Where can I learn about new or changed features for each release?

To learn about new features for the release, review the What's new.

Where can I access known issues for each release?

To review known issues and limitations, go to Known issues.

Where can I find terms and definitions for IBM Cloud Pak for AIOps?

Terms and definitions for IBM Cloud Pak for AIOps can be found in the Glossary.

Where can I find out about deprecated and removed functions?

To find out more about deprecated and removed functions, go to Deprecated and removed functions.

About installing the Cloud Pak

- Where can I find Cloud Pak for AIOps installation documentation?
- Where can I learn about the Hardware requirements for Cloud Pak for AIOps?

Where can I find Cloud Pak for AIOps installation documentation?

AIOps installation documentation can be found here.

Where can I learn about the Hardware requirements for Cloud Pak for AIOps?

Hardware requirements for Cloud Pak for AIOps can be found at Hardware requirements.

About administering and setting up the Cloud Pak

- Where can I learn about administering the Cloud Pak?

Where can I learn about administering the Cloud Pak?

To find out more about administration tasks such as adding users, backing up and restoring, and more, go to Cloud Pak administration.

About integrating with the Cloud Pak

Integrations in Cloud Pak for AIOps

There are over 160 industry standard integrations in Cloud Pak for AIOps, which ingest Events and Alerts, Metrics, Topology, and Logs from across your estate and tooling. You can create your own custom integrations using generic integrations and SDKs. You can also leverage your existing Netcool Probes. Cloud Pak for AIOps provides integration configuration and management.

Which types of data are collected by Cloud Pak for AIOps?

There are two types of data collected: structured and unstructured. Structured data includes logs, tickets, and CI/CD, while unstructured data includes events (alerts), metrics, and topology changes.

IBM Tivoli Network Manager deployment and integration

Where IBM Tivoli Network Manager is present, it should be deployed in a resilient manner and connected to a Netcool/OMNIbus ObjectServer. Any events it generates flows into AIOps through the Netcool Connector. An instance of DASH and Netcool/OMNIbus WebGUI with Topoviz installed is needed to access Structure Browser views. Its topology can be brought into the Cloud Pak for AIOps through the IBM Tivoli Network Manager Observer.

What are best practice guidelines when including Netcool components with the Cloud Pak?

The necessity to include Netcool components in an AIOps deployment depends on your requirements when planning. Where Netcool components are needed, their deployment should be governed by best practices. Some guidelines include:

- All Netcool components should be deployed with the latest fix pack applied
- All components should be deployed in a resilient manner
- All components should be configured to auto-start on machine boot

How do I initiate custom integrations, automations and workflows with IBM Netcool/Impact

Any custom integrations, automations, or workflows that are done by using Netcool/Impact can either be automatically initiated from the Netcool/OMNIbus Aggregation ObjectServer pair through an Event Reader, or from AIOps directly with the Netcool/Impact Connector.

How does Infrastructure Automation (IA) work with AIOps?

You can manage your environment with infrastructure automation and take incident-resolving actions directly from Cloud Pak for AIOps. Infrastructure Automation that are used along with Cloud Pak for AIOps allows for:

- Discovery of existing VMs
- Inventory and lifecycle management of infrastructure
- Compliance and policy Management of VMs
- Chargeback and reporting
- Day 2 provisioning of VMs
- Running of playbooks to automate VM and middleware configuration
- Configuration actions to remediate policy violations with Ansible

About the features of Cloud Pak for AIOps

How does Cloud Pak for AIOps calculate change risk?

Cloud Pak for AIOps discovers the relationship between changes and incidents for risk prediction. It uses state-of-the-art deep learning models for change request prediction risk, and provides explainability by presenting prior, related changes that were problematic, and uses state-of-the-art deep learning models for change request.

How are incidents handled in Cloud Pak for AIOps?

Cloud Pak for AIOps provides a complete overview/integration of your existing operational data: Events, Metrics, Logs, Topology across your silos. No change is needed in instrumentation.

It provides event processing, compression, and correlation to identify service-impacting events, and early detection of anomalies across events, metrics, and logs to enable proactive issue awareness and increased context for an incident.

It also gives probable cause localization and blast-radius to know what caused the problem and what is affected.

How does Cloud Pak for AIOps help you resolves issues?

It applies recommended actions to remediate the issue right away, and allows you choose the level of automation right for the task, from manual step-by-step guidance to semi-automated with guidance and automated commands to full auto-triggered automation. It also allows you collaborate and align across teams by using automatically generated enriched Ops information, analysis and guidance.

How does Cloud Pak for AIOps help you understand your managed environment?

Cloud Pak for AIOps help you visualize and understand your heterogeneous environment, including key metrics from a single screen. It offers a comprehensive application representation, even when “truth” spans multiple sources of insight. It gives a full view of changes to your environment using an historic timeline.

What are the different types of event correlation in Cloud Pak for AIOps?

Cloud Pak for AIOps uses **three different event correlation methods** that work together to correlate events.

- **Temporal**

  Event analytics groups events that have always suspiciously occurred together in the past.

- **Scope-based**

  Operations can define their own groupings based on local knowledge.

- **Topology-based**

  Defines templates for groups of related resources. Cloud Pak for AIOps automatically finds all examples that match the recipe.

What is log anomaly detection?

It is the detection of anomalies from log messages and includes:

- Anomalous time period prediction
- Entity mentions in error logs
- Explanation and pointer to log messages from anomalous time periods

What is metric anomaly detection?

It is the detection of anomalies from time series metrics including:

- Deviation from normal operating range
- Change from variable to flat
- High and low range changes
- Exceed previous range
- Exceed normal range variance

What is probable cause?

You can derive probable fault components using vertex-weighted topology graph traversal and a reasoning engine to understand the meaning of the topology relationships. It allows for localization to the most likely source of an issue within the application topology.

What is incident similarity?

For a given problem description, it helps find top 'k' ranked similar incidents from the past. It helps you understand the current issue and previous successful resolved actions. it consumes tickets and any data from the ticket progression to closure, including human-written investigation and resolution actions. It uses entity-action extraction and action sequence mining to understand tickets and summarize what was done.

What is fault localization and blast radius?

You can derive the full scope of components by using vertex-weighted topology graph traversal and a reasoning engine to understand the meaning of the topology relationships. It allows for blast-radius through directional dependency analysis of the related components that interact with the localized source of the issue.

What is event seasonality?

With event seasonality you can automatically discover events that occur with a regular pattern, which helps you identify chronic issues that can go undetected, provides valuable insights into problem-solving, and also continuous learning over days, weeks, months, and years.

What is change risk prediction?

It allows you assess the risk for each proposed change based on issues that are caused by historical changes. You can harvest and analyze the change ticket history to identify changes that implicitly failed when applied. You can also identify changes that resulted in subsequent issues if they rolled out.

What is event grouping with entity linking?

It groups events, alerts, anomalies to reduce tickets. These can be:

- Topological - which are group events that are related or connected (or both)
- Temporal - which is how you automatically discover events that tend to co-occur
- Scope - which automatically groups events based on scope
- Supergroup - which is a group of groups

What are the characteristics of Cloud Pak for AIOps algorithms?

- **Preprocessing**

  Each algorithm has its own preprocessing chain, which performs a chained set of transforms on the data, and Cloud Pak for AIOps validates the data fits the algorithm and will result in successful training.

- **Unsupervised**

  Algorithms built by IBM using tested data to validate the algorithms. The algorithm builds models without labels. Cloud Pak for AIOps algorithms create models of “normal” based on your data.

- **Validation**

  Understand if the model is not overfitting or underfitting the data. The algorithms self-adjust the model over time.

What are the advantages of AI-powered over traditional incident management?

IT teams rely on incident management to find and fix any number of unplanned events, from the mundane to the profound. The question to ask is as your systems have evolved, has your approach to incident management kept pace? An AI-powered solution can help you stay competitive and keep your business operations running smoothly. The advantages include:

- **Reaction time**

  AI-powered incident management offers teams proactivity and efficiency. It automatically analyzes information from the environment to discover, predict, and prevent incidents before they can impact business processes, which can result in faster time to identify incident causes, and helps maximize uptime and enhance customer satisfaction.

- **Data management**

  IT ingests and correlates data from various sources to provide a comprehensive view of the entire IT landscape. It helps IT operation teams quickly identify the underlying causes of incidents. It promotes collaboration between teams, subject matter experts, and stakeholders. It expedites incident resolution, reduces Mean Time To Repair (MTTR) and improves overall operational efficiency.

- **Scalability**

  AI and automation enable scalability. AI can analyze vast amounts of data in real time to handle increases in the volume and variety of incidents. Teams can more effectively manage incidents, regardless of the size and sophistication of their IT environment.

- **Predictability**

  AI anticipates issues and prevents them proactively. It can detect thresholds automatically and identify patterns, trends, and potential risks that can lead to incidents. It enhances operational efficiency by empowering preventive actions, such as proactive maintenance and capacity adjustments, that reduce the likelihood of incidents occurring.

What is Similar ticket analysis?

Similar tickets is an unsupervised learning algorithm that aggregates information about similar messages, anomalies, and events for a component or a service. It can also extract the steps used to fix previous incidents, if documented. It does this by connecting to your ServiceNow instance and analyzes the existing tickets therein. After training has completed, AIOps will automatically alert users working on an incident to any tickets raised in the past that are similar.

Overview of IBM Cloud Pak for AIOps

IBM Cloud Pak® for AIOps is an AIOps platform that deploys advanced, explainable AI using the IT Operations (ITOps) toolchain data so that you can confidently assess, diagnose, and resolve incidents across mission-critical workloads.

IBM Cloud Pak for AIOps eases the path to adopting advanced AI for ITOps to decrease your operational costs. With this Cloud Pak, you can increase your customer satisfaction by proactively avoiding incidents and accelerating your time to resolution.

The scale of IT systems and their complexity is continually increasing over the last few years because of digital transformation, containerization, and hybrid cloud adoption. IT teams are being inundated with routine maintenance activities and expanding cloud services, leaving them little or no time to contribute toward innovation. To accelerate business automation, reduce complexity, save costs, and automate regular tasks, companies must use the power of AI.

IBM Cloud Pak for AIOps powers automation by using diverse data sets from an entire range of hybrid environments from cloud to on-premises, and bringing the information together across ITOps. With this Cloud Pak, you can tap into shared automation services to get insight into how your processes run. You can also visualize hotspots and bottlenecks, and pinpoint what to fix with event detection to prioritize which issues to address first.

IBM Cloud Pak for AIOps helps you uncover hidden insights from multiple sources of data, such as logs, metrics, and events. The Cloud Pak delivers those insights directly into the tools that your teams already use, such as Slack or Microsoft Teams, in near real-time. Included AI management tools provides you with unprecedented visibility into your organization's infrastructure so that you can predict failures and facilitate problem resolution.

For information about the IBM Cloud Pak for AIOps architecture, see Architecture.

Concepts

IBM Cloud Pak for AIOps represents the state of managed entities by using the following three concepts:

- Events, which are a record containing structured data that summarizes key attributes of an occurrence on a managed entity. Events indicate a change in the state of a service or a system. Events are a category that includes the raw data, alerts, and incidents.
- Alerts, which represent an ongoing anomalous condition against a single managed entity. An alert might evolve over time as the condition changes, and extra context, and insights can be associated with it. An alert presents a single symptom, typically composed of one of more signals, which are immutable, and point-in-time statements about the entity in question.

  For example, an alert which indicates that a given resource is using 100% of its available storage is made up of multiple incoming signals of the disk usage at different times. The alert represents the ongoing time span that the resource in question is in this state.
- Incidents, which represent the context around an issue currently impacting operations. An incident is a collection of insights that come from different data sources, such as events, topology, and logs. Incidents bring together key elements to provide a holistic view of the problem. These elements include alerts, information about how the affected resources are related, guidance on possible resolutions, and automations to remediate the issue. A key difference from an alert is that while an alert has context and insights on a single entity, and a single symptom (alert type), an incident brings together all the symptoms for a more comprehensive understanding. The creation and evolution of incidents are informed by alerts.

  For example, an incident might bring together alerts on a full disk, alerts on increased request failures, and alerts on application failures. These lists of alerts can be paired with guidance on how to address each separate problem and automations, which can perform the solutions.

Features and benefits

With IBM Cloud Pak for AIOps, you can accelerate your journey toward AI powered operations. You can use the Cloud Pak to set up an integrated, AI-driven set of tools to pull, and analyze data from multiple IT platforms to help with ITOps management. IBM Cloud Pak for AIOps combines a set of capabilities to provide a single solution that facilitates predicting, communicating, and resolving events before they become serious problems. Issues are inevitable in any IT landscape, it's how and when you respond that can make a world of difference to your organization.

IBM Cloud Pak for AIOps includes the following key features:

- Guided tours
- Integrations and data ingestion
- Integrations and data ingestion
- AI modeling and training
- Resource management
- Topology
- Log anomaly detection
- Metric anomaly
- Event grouping
- Similar ticket comparison
- Incidents and alerts
- ChatOps
- Automations
- Change risk
- Additional capabilities
  - Infrastructure automation

These capabilities are supported by a network of integrations and capabilities that manage all facets of the AIOps lifecycle from model training to execution.

IBM Cloud Pak for AIOps collects information from all of your IT assets, such as applications, the infrastructure that they run on, and the networking systems that support them. It then uses that data to uncover hidden insights and identify root causes of events. Using this data to train your models lead to better event discovery and a more accurate understanding of your topology. With this advanced understanding of your topology, you can pinpoint where events occur and how far-reaching their impact is. When IBM Cloud Pak for AIOps detects potential incidents, it creates an incident about the incident. Then, it uses a ChatOps environment, such as Slack or Microsoft Teams, to notify, update, and provide your team with near real-time potential remedies, which empowers your teams to automate tasks with clear and open AI decision-making.

The user experience is simplified around AI lifecycle management. The modern experience breaks the complex task of AI model training into a simpler milestone-based experience. This makes it easier for any user to select, filter data, train the models, and view the progress and its output. Through this new experience, you can train the built-in AI models of change risk, event grouping, log anomaly detection, and similar tickets with your data with just a few clicks.

Guided tours

First-time users are presented with a guided tour upon login. This tour is customized for IBM Cloud Pak for AIOps to introduce users to the various home page components, shows how to access tools and capabilities, and where to complete key tasks across the platform.

The home page content is customized based on the user's role-based access. The initial tour shows the user the following components:

- Insights-related summary cards that provide a high-level glance at important metrics in the environment. These insights are related to only the components that the user has access to view or manage.
- The *Quick navigation* and *Support* links for easily accessing commonly used tools, product documentation, IBM Support, and more.
- The main navigation menu for the IBM Cloud Pak for AIOps console, which lists the tools and pages that are accessible by the user.
- The *Tours* menu for accessing more tours and guidance on how to use the Cloud Pak for AIOps console and completing essential tasks. The tour menu includes links for the welcome tour, and for tours to help get started with integrations and AI modeling.
- The getting started links for setting up integrations, learning more about IBM Cloud Pak, and managing user access control.

More tours can be accessed at any time by the user to get a better understanding of how to get started with different tasks and components. Users can select a tour by clicking the **Tours** icon in the Cloud Pak for AIOps console toolbar, and clicking their preferred tour. The following overview tours are available for IBM Cloud Pak 4.8.0:

- **Welcome to IBM Cloud Pak for AIOps**

  A repeat of the initial *Welcome* guided tour.

- **Discover AIOps insights**

  Overview of the AIOps Insights dashboard, which summarizes how IBM Cloud Pak for AIOps helps organizations anticipate, troubleshoot, and resolve IT incidents. The tour loads sample data to walk the user through available toolbars and charts, including Mean time to restore, Noise reduction, Incident activity, and Runbook usage.

- **Start with integrations**

  Available from the Integrations and the home page. This tour guides users through the Integrations to show how to add integrations between IBM Cloud Pak for AIOps and other tools.

- **Introduction to resource management**

  Available from the *Resource management* tool. This tour identifies the resource management capabilities, which you can use to gain an overview of applications, resource groups, and resources and select them to view their details and topology. The tour introduces you to resource groups, which you can use to build application definitions. These resource groups are created automatically when you connect tools, however, you can add groups by using the template page.

- **Understand applications and resource groups**

  Available from the *Resource management* tool when a user selects an application or a resource group to view details. This tour shows a user how to view incident details, view affected resources, view and navigate the timeline, and how to get insights from changes to a resource over the time.

- **Learn about the timeline**

  Available from the *Resource management* tool. This tour is available when a user selects to view details for an application that has an associated incident. This tour walks the user through the details of the timeline widget, showing how to interact with the data and see changes that have occurred for alerts.

- **Explore AI modeling**

  Available from the AI Model Management and the home page. This tour helps you to understand the two types of AI algorithms that are available to enable AI modeling. This tour uses the *Change risk model* summary card to show you how to set up and monitor the training of model-generating algorithms.

- **Introduction to automations**

  Available from the *Automations* tool, which the user can use to proactively set up actions and policies to detect and remediate events, both current and future. With this tour, a user learns how to create policies, view policy details, create and view runbooks, and more.

- **Create a new policy**

  This step-by-step tutorial is available from the *Automations* tool to guide users in the creation of a new policy. This step-by-step tutorial uses the *Promote alerts to an incident* policy template to help you understand the basics of setting up a new automation policy.

- **Introduction to incidents and alerts**

  Available from the *Incidents and alerts* tool. This tour provides an overview of how incidents bring insights together to present the holistic view of an incident. The tour guides you through the different tabs, options, and views of the *Incidents and alerts* tool to show you how to view your existing incidents and alerts, including how to filter the incident list, drill down to view alert details, clear alerts, and more.

- **Investigate an incident**

  Available from the *Incidents and alerts* tool when a user views an incident in detail. This tour guides a user through the process to investigate an incident. A user is introduced to how to view probable causes and top alerts, review associated automations, change incident settings, investigate incident alerts, and how to visualize an incident. The tour also introduces details on incidents, trigger alerts, and the legend and timeline for visualizing an incident.

Integration and data ingestion

Data is the life blood of AI but configuring data feeds can be complex. You can use the Cloud Pak for AIOps console tools to set up integrations to a wide variety of systems for data ingestion. IBM Cloud Pak for AIOps supports integrations to large system solutions including log management, event management, and service management tools within an IT environment, such as Splunk, Falcon LogScale, Mezmo, PagerDuty, and ServiceNow. You can also use the Netcool probes to ingest events into IBM Cloud Pak for AIOps.

A gRPC framework is used for some integrations to support local or remote deployment of a bidirectional data flow. These integrations, such as the Instana and Slack integrations, can be deployed locally in the same project (namespace) as IBM Cloud Pak for AIOps, or deployed remotely.

IBM Cloud Pak for AIOps provides many connectors, probes, and observers by default for setting up integrations with common IBM and third-party systems and services. In addition, if a default integration is not available for connecting to a system or service that you want to use with IBM Cloud Pak for AIOps, you can set up a custom integration to connect to that system or service.

For more information about setting up integrations, see the following sections:

- Defining integrations
- Available integrations

Netcool integrations

Integrations are available for connecting IBM Tivoli Netcool/OMNIbus and IBM Tivoli Netcool/Impact.

A *Netcool* integration is used to define an integration to IBM Tivoli Netcool/OMNIbus. An IBM Tivoli Netcool/Impact integration is used to define an integration to IBM Tivoli Netcool/Impact. For more information about these integrations and integrating with Netcool, see Netcool integrations.

Instana integrations

An Instana integration is available for connecting with Instana to enable connectivity to Instana events, metrics, and topology. Instana assets can now be combined with IBM Cloud Pak for AIOps AI, such as runbooks, metric anomaly detection, and log anomaly detection to help you gain insights. For more information about setting up this integration, see Creating Instana integrations.

Ansible integrations

IBM Cloud Pak for AIOps also includes Ansible integration for connecting to Ansible and an SSH integration to connect with another system where scripts and commands can run.

The Ansible integration provides you with the ability to set up a integration to an Ansible automation platform controller server to gain benefits from the configuration and orchestration capabilities of Ansible. For more information about setting up the integration, see Ansible automation provider.

The SSH integration is agentless and connects directly to the target machine. It authenticates by using SSH public key authentication. You can only create one SSH integration. For more information, Creating SSH integrations.

AI modeling

You can train AI models to hone its ability to derive insights from your incoming data integrations. To get the most out of your AI models, you can manually map your log data to the JSON training format and train your models with it. For more information about training specific types of models, including suggested mappings for events and logs, see the following training topics:

- About AI algorithms
- Configuring AI models

For more information about what you can do to gain further insight into your IT infrastructure, see the following topics:

- Navigating the ChatOps interface
- Managing incident

For guidance on how to plan data integrations and AI model training, see the following topic: Planning data loading and training.

Resource management

IBM Cloud Pak for AIOps brings together the capability to group resources from different data types into applications (services). You can flexibly define an application (service) to meet your business needs. With applications (services), you can obtain an integrated view of your resources to understand inter-dependencies.

IBM Cloud Pak for AIOps focuses on the user experience and health of your applications (services). This application-centric approach uses a built-in application template model to dynamically aggregate and group tagged resources to enable rapid visualization of different application components.

Topology

An integrated service and topology management and topology viewer provides complete up-to-date visibility of your applications and resources, and provides you with control over dynamic infrastructure and services. You can configure your topology visualizations to also show real-time or historical data.

In addition, to help you pinpoint incidents within applications and resource topologies, IBM Cloud Pak for AIOps tools work together to correlate events.

Log anomaly detection

IBM Cloud Pak for AIOps includes a pair of AI algorithms to gather log data from one or multiple components in the application architecture to identify a baseline of expected log message types. IBM Cloud Pak for AIOps uses this baseline to discover abnormal behavior in your live log data. These AI algorithms can run independently of the other. If both algorithms are enabled, then any log anomalies discovered by both are reconciled, so that only one alert is generated. In this case, the severity of the combined alert is equal to the highest severity of the two alerts. Each algorithm is used to gather data differently:

- Natural language log anomaly detection uses natural language techniques on a subset of your log data to discover abnormal behavior. This log anomaly detection takes large amounts of log data and trains on it to learn what is normal behavior for a particular component. This model goes beyond just looking

at error states or frequency of metadata around log messages. Instead, it determines when something becomes an anomaly compared to what patterns it typically exhibits.

- Statistical baseline log anomaly detection uses a statistical moving average on all of your log data to discover abnormal behavior. This algorithm automatically detects unusual patterns in logs and notifies you when they occur. Data that is used for analysis is updated every 30 minutes so this algorithm provides value quickly.

Note: This feature is only available for extended deployments. For more information about deployment types, see Incremental adoption.

For more information, see Log anomaly training definition.

Metric anomaly

Metric anomaly detection provides the ability to analyze any time series metric automatically using AI without the need for configuration or tuning. This AI leverages the Instana Integration, automations, and policies. You can group metric anomalies with log anomalies and other Alerts.

Metric anomaly detection can help you measure key performance indicators, like memory availability or latency, to identify trends and deviations in these areas early.

For more information, see About metric anomaly detection.

Event grouping

AI algorithms are provided with IBM Cloud Pak for AIOps to group events together and present the events within a single incident.

- Temporal grouping is used to group events that are discovered to co-occur over time. When a problem arises, typically multiple parts of a system or environment are impacted. When events in different areas co-occur, it makes sense to look at them together and treat them as one problem to try to determine what might have occurred. Grouping co-occurring events together reduces the number of tickets and incidents that are opened and the number of people looking at the same problem, thereby significantly reducing noise in your monitoring systems. It helps you to understand the context of an issue so you can prioritize, triage, and resolve it more quickly.
- Topological grouping is used to group events based on the resource groups in which events occur. For example, if you have a resource group that is made up of all the resources within a given Kubernetes namespace, then any events on pods, microservices, or other resources in that namespace are grouped together in a single topological group. Topological grouping helps you understand when events are connected based on their topology, providing valuable context for why related events might occur together.
- Scope-based grouping automatically groups events relating to an incident if they have the same defined scope and occur during the same period. A scope can be used to identify where events originate based on a common attribute, for example, the location of a server room. By understanding when events are related based on both time and location, you can more quickly diagnose incidents.

For more information, see Event grouping training definition.

Similar ticket comparison

The similar ticket AI algorithm in IBM Cloud Pak for AIOps can be used to define an AI model so that when incidents occur, the model can review details for similar tickets from the past to help determine a resolution to current problems. This model aggregates information from past similar tickets. It can also extract the steps that are used to fix previous incidents, if documented. This AI algorithm discovers details about similar messages, anomalies, and events within your tickets that occurred in the past and are impacting the current application. For more information, see Setting up training for similar tickets.

Note: This feature is only available for extended deployments. For more information about deployment types, see Incremental adoption.

Incidents and alerts

IBM Cloud Pak for AIOps enables you to identify health issues across your application, services, and network infrastructure on a single management console. It provides a Incidents and alerts tool that brings together incidents, alert details, alert severity, and alert filtering. This capability helps you to analyze the context of incidents across the full enterprise estate. This viewer acts as a single pane of glass incident dashboard, which displays key details like the probable cause, topology, and associated automations to resolve the incident.

Some alerts in the console are presented in alert groups, based on analytics. By using the alert list, you can explore why these alerts were grouped together, and this understanding can further help with alert resolution.

Alerts are displayed in the Alert Viewer. From a ChatOps integration (Slack or Microsoft Teams), you can launch into an Alert Viewer that shows the alerts that are associated to a specific incident.

For more information, see Managing incidents and alerts.

ChatOps

IBM Cloud Pak for AIOps ChatOps support includes integrations with existing social collaboration tools, Slack, and Microsoft Teams. These integrations help to deliver AI-powered automation for ITOps and management within their preferred collaboration tool of choice.

From a ChatOps integration you can launch into the Cloud Pak for AIOps console Incidents and alerts tool to view more information about an alert that is being viewed in ChatOps.

IBM Cloud Pak for AIOps uses ChatOps to provide a message-based interface for reporting incidents with the ITOps that you are monitoring. This ChatOps interface displays the following types of operations information:

Table 1. Operations information available from the ChatOps interface

Operation	Description
Anomaly Detection	Provides details about detected anomalies in your real-time or offline data, such as the time when the incident was detected, the incident description, status, and more.
Relevant events	Groups-related events to aid incident diagnosis. Events can include alerts, PagerDuty alerts, or log anomalies.

Operation	Description
Probable cause	Derives root fault component, and derives the full scope of components that are affected by an incident.
Ticket Similarity	For a particular ticket, finds the highest "n"-ranked similar tickets from the past.
Next Best Action	For a particular incident, suggests the highest "n" actions from similar tickets from the past.

Automations

with IBM Cloud Pak for AIOps an engine and UI for automation is included that you can use to create automation policies, runbooks, and actions to help you resolve incidents quickly by setting up and enabling an automatic response as situations arise. Starting up additional capacity or restarting a failed service can happen before your team knows there is an issue.

For setting up automated procedures, you can proactively set up policies, runbooks, and actions to detect and remediate events, both current and future.

- Policies are rules that contain multiple condition and action sets. They can be triggered to automatically promote events to alerts, reduce noise by grouping alerts into an incident, and assign runbooks to remediate alerts. For more information, see Policies.
- Runbooks automate procedures that do not require human interaction, thereby increasing the efficiency of IT operations processes. With runbooks, your operators can spend more time innovating and are freed from performing time-consuming manual tasks. For more information, see Runbook Automation.
- Actions in runbooks are the collection of manual steps grouped into a single automated entity. An action improves runbook efficiency by automatically performing procedures and operations. For more information, see Actions

Change risk

IBM Cloud Pak for AIOps includes an AI algorithm for providing change risk assessment and includes the capability of surfacing change risk assessments through ChatOps.

The change risk AI algorithm provides an assessment of the risk of implementing a proposed change; for example, a code change or a new software version. Hundreds of changes can affect an application during its lifecycle. Change risk correlates historical change data with historical incident data and determines how likely it is that a specific code change would cause a problem. Using the assessment percentage provided, you can determine how safe it is to proceed with the change. Training this AI model can help you ensure that risky changes for an application are assessed before deployment. For more information, see Change risk training definition.

The change risk assessment in ChatOps provides you with a model confidence percentage that represents the confidence in the AI's prediction of the impact of a change. This percentage is relative to the risk associated with a new or updated ServiceNow change request ticket. The model confidence percentage is calculated based on the change risk AI model that is based on the change risk AI algorithm and the data that you feed into it. Change risk can be evaluated based on any type of change, whether it is changes to code, or to configurations, or to data. If you have historical change request tickets for that type of change, IBM Cloud Pak for AIOps can provide a model confidence percentage for it. For more information, see Change risk in ChatOps.

Note: This feature is only available for extended deployments. For more information about deployment types, see Incremental adoption.

Infrastructure automation

Infrastructure automation is included as an optional feature with IBM Cloud Pak for AIOps. This Infrastructure automation component consists of the following components, which were available with IBM Cloud Pak for Multicloud Management:

- Infrastructure management, previously called IBM Red Hat CloudForms.
- Managed services, previously called Terraform & Service Automation or IBM Cloud Automation Manager.

Infrastructure management delivers the insight, control, and automation enterprises need to address the challenges of managing virtual environments, which are far more complex than physical ones. This technology enables enterprises with existing virtual infrastructures to improve visibility and control, and those just starting virtualization deployments to build and operate a well-managed virtual infrastructure.

Managed services provide you with the capability to automate provisioning of infrastructure and virtual machine applications across multiple cloud environments with optional workflow orchestration.

Infrastructure automation enables IT Operations and Site Reliability Engineer (SRE) teams to use infrastructure as code practices to drive IT velocity and shift to the left of operations.

Infrastructure automation is installed within a separate cluster from IBM Cloud Pak for AIOps. For more information, see Infrastructure automation.

Bringing the features together

By combining AI-driven insights with a modern user experience, you can achieve reduced Mean Time to Resolution (MTTR) when an incident occurs and avoid incidents in the first place through a change risk advisor. The user experience brings in different types of data together and builds out an application perspective, delivering unique insights from the AI models.

Application impact avoidance

The trained AI models establish a baseline and automatically detect anomalies across structured and unstructured data. The models reduce noise and bring related entities across different data sets together into a complete “incident” ahead of a potential incident or application impact. A much smaller set of high-impact “incidents” versus a flood of events and incidents, provides deep insights with explainability.

These incidents help you to visually understand the probable cause to help prevent future downstream impact. The Next Best Action recommendation from past incidents, and the built-in Runbook Automation capabilities accelerate the time to remediation of an incident. The probable cause capability allows users to isolate and find the root cause of the problem faster.

Incident diagnosis

- Derive root fault component and probable cause of affected components to isolate problems faster.
- Detect anomalies by using automatic parsing to detect anomalies in logs and alerts earlier than rule-based alerts.

Insight delivery

- Integrate with pre-trained AI models to gain new insights from existing tools. Keep teams focused, surfacing insights and recommendations into existing workflows.
- Avoid application impact through correlating data across all relevant data sources. Detect hidden anomalies, anticipate issues, and resolve faster. Correlate a vast amount of unstructured and structured data in real time with AIOps tools.
- Proactively avoid risks and automate runbooks for more efficient workflows.
- Proactively avoid incidents with explainable AI that advises based on inputs across ITOps.
- Create a visual representation of the data that is flowing through your business and pinpoint bottlenecks in your operations.
- Draw on advanced AI and analytics to create a baseline that you'll use to track key performance indicators (KPIs) over time.

Architecture

IBM Cloud Pak® for AIOps combines a set of capabilities to provide a single solution that facilitates predicting, communicating, and resolving events before they become serious problems.

IBM Cloud Pak for AIOps integrates infrastructure and operations management into a single coherent structure across business applications, virtualized servers, network devices and protocols, and security and storage devices. IBM Cloud Pak for AIOps enables CIOs, site reliability engineers (SREs) and IT Operators by uncovering hidden insights from multiple sources of data (like logs, metrics, and events). It delivers those insights directly in to the tools that teams work with (like Slack, Microsoft Teams, and ServiceNow) in near real-time, and also presents them in a web-based user interface.

The core functions of IBM Cloud Pak for AIOps can be categorized into five capabilities: event management, incident detection and resolution, entity extraction, and insight delivery. These capabilities are supported by a network of integrations that gather data. It also offers all facets of the AIOps lifecycle from model training to execution. These capabilities are bolstered by IBM Cloud Pak foundational services.

A deployment of IBM Cloud Pak for AIOps can be a base deployment or an extended deployment that has log anomaly detection and ticket analysis (similar incidents and change risk) capabilities enabled. For more information about base deployments and extended deployments, see Incremental deployment.

For more information about the possible deployment configurations, see the following topics:

- Deploying IBM Cloud Pak for AIOps on OpenShift
- Deploying IBM Cloud Pak for AIOps on Linux

For more information about how these capabilities come together in IBM Cloud Pak for AIOps, see:

- IBM Cloud Pak for AIOps
- Infrastructure Automation
- IBM Cloud Pak for AIOps with Infrastructure Automation

IBM Cloud Pak for AIOps architecture

IBM Cloud Pak® for AIOps combines a set of capabilities to provide a single solution that facilitates predicting, communicating, and resolving events before they become serious problems.

The following sections illustrate how these capabilities come together in IBM Cloud Pak for AIOps:

- Features and Capabilities
- Deployment architecture
- Data flow architecture
- Extensibility architecture

Features and Capabilities

IBM Cloud Pak for AIOps is installed on Red Hat® OpenShift® Container Platform or Linux®. For more information about the supported platform versions, see the following topics:

- Supported Red Hat OpenShift Container Platform versions
- Planning an installation of IBM Cloud Pak for AIOps on Linux®

When installed, IBM Cloud Pak for AIOps includes access to the IBM Cloud Pak for AIOps console. This UI is a web-based application for accessing features and capabilities for IBM Cloud Paks, such as IBM Cloud Pak for AIOps. If you have multiple IBM Cloud Paks that are installed in the same environment, you can switch between working with each IBM Cloud Pak from this single UI.

Installing IBM Cloud Pak for AIOps gives you access to the following features and capabilities:

- AI modeling
- Applications
- Change risk
- Data ingestion
- Event grouping
- Log anomaly detection

- Metric anomaly detection
- Resolution automation (Runbooks, Policies, Actions)
- Similar incident comparison
- Incident management
- Topology

For more information about these features and capabilities, see features and capabilities.

Deployment architecture

The IBM Cloud Pak for AIOps deployment model requires a deployment on a Red Hat OpenShift Container Platform or Linux cluster. Data sources are configured with it for events, topology, metrics, and logs.

An IBM Cloud Pak for AIOps deployment can resemble the following diagrams. This diagram shows optional IBM Tivoli Network Manager and IBM Tivoli Netcool/Impact integrations.

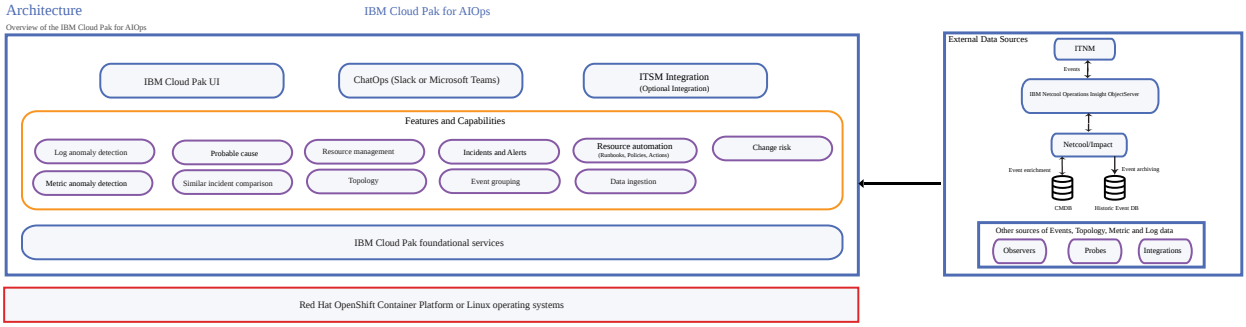

Figure. Architecture with Netcool components

This diagram shows the architecture without Netcool components.

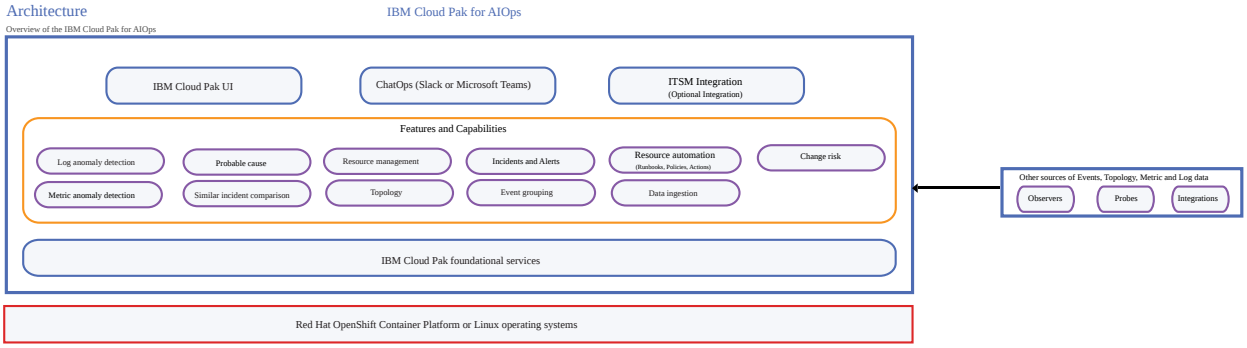

Figure. Architecture with no Netcool components

From these base deployments, there are typically two deployment patterns:

- You have Netcool components and want to reuse them with IBM Cloud Pak for AIOps.
- You have no Netcool components to reuse.

In the case where existing Netcool components exist, you can connect to them similar to how you can connect to other data sources through an integration. In this case, you would use the Netcool integration. This integration allows IBM Cloud Pak for AIOps to receive all the events in the IBM Tivoli Netcool/OMNIbus components (typically deployed on VMs).

Notes:

- A separate Netcool integration must be set up for each Aggregation ObjectServer pair that is present. The IBM Cloud Pak for AIOps schema must be normalized by using the mapping in the Netcool integration.
- Events flowing through integrations to IBM Cloud Pak for AIOps, aside from events that are sent through the Netcool integration, do not flow back to IBM Tivoli Netcool/OMNIbus. To handle custom enrichments or logic, use a IBM Tivoli Netcool/Impact integration with IBM Cloud Pak for AIOps.
- Event archiving to the REPORTER database can be done either directly from IBM Tivoli Netcool/OMNIbus, or by using IBM Cloud Pak for AIOps to feed events to IBM Tivoli Netcool/Impact. This process inserts the events into the event archive directly.
- Where IBM Tivoli Network Manager is present, it must be deployed in a resilient manner and connected to a IBM Tivoli Netcool/OMNIbus ObjectServer. This requirement is because IBM Tivoli Network Manager connects to IBM Tivoli Netcool/OMNIbus in two ways:
  - The IBM Tivoli Network Manager Gateway reads events from IBM Tivoli Netcool/OMNIbus and does root cause analysis and enriches them with topology metadata.
  - The IBM Tivoli Network Manager Probe sends events to the ObjectServer.

  It is more efficient to continue to connect IBM Tivoli Network Manager through a IBM Tivoli Netcool/OMNIbus integration as any events it generates flows into IBM Cloud Pak for AIOps.
- Any custom integrations, automations, or workflows that are done by using IBM Tivoli Netcool/Impact can either be automatically initiated from the IBM Tivoli Netcool/OMNIbus Aggregation ObjectServer pair by using an Event Reader, or from IBM Cloud Pak for AIOps directly by using the IBM Tivoli

Netcool/Impact integration.

Data flow architecture

IBM Cloud Pak for AIOps consists of many interconnected components. The following diagram shows an example of these interconnected components:

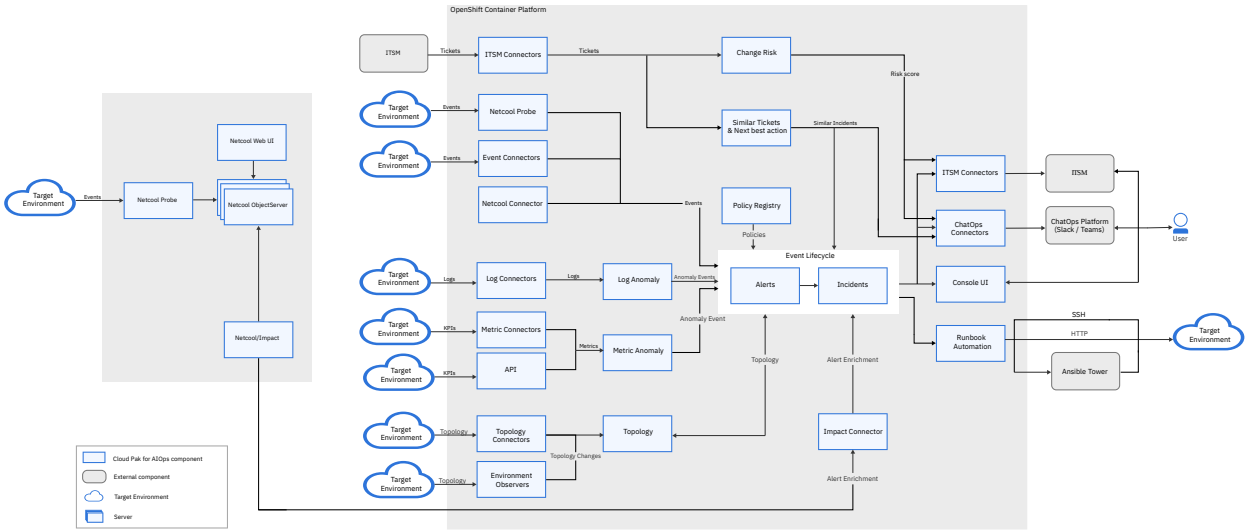

Figure. Data flow

The main workflow is the ingestion of events. Events are ingested from various sources, such as through integrations and Netcool probes. These events proceed through the event lifecycle, where de-duplication, suppression, correlation, incident creation, and many more insights and contexts are added. The resulting alerts and incidents are available to IT Operators through the IBM Cloud Pak for AIOps console, ChatOps, ITSM (ServiceNow) and APIs. In addition, the lifecycle incorporates automation through Runbooks to augment the alert or incident with additional diagnosis or attempts to automatically remediate the incident.

The next workflow brings in topology from the different observers of the estate. Topology merges these topology resources into a holistic view. It augments the topology with the observed events, as well as contributes to the context of alerts and incident and to insights. For example, underpinning the topological correlation and probable cause algorithms.

Both logs and metrics are brought in to provide more insights. They are analyzed for anomalies, which are then correlated into the incidents hence contributing to the full picture.

Finally, tickets are optionally created for the incidents to serve as a record of the incident. Resolved tickets are then ingested to provide context of similar occurrences in the past through similar tickets, and to convey the risk of a change request.

Extensibility architecture

IBM Cloud Pak for AIOps is highly extensible and customizable. IBM Cloud Pak for AIOps can include integrations for many of the popular data sources, events, metrics, logs, topology, and tickets. In addition to these default integrations, support is included for integrating with custom data sources, topology observers, and Netcool probes.

IBM Cloud Pak for AIOps supports a rich set of APIs allowing widespread integration. These APIs include retrieving and updating alerts, incidents, metrics, runbooks. For more information about API section, see APIs.

- For custom integrations without coding, IBM Cloud Pak for AIOps supports the use of webhook APIs for logs and events, the use of Kafka for logs and events, and the use of file-based integrations for topology. Custom metrics can be provided by using the metrics REST API.
- For building custom integrations with coding, IBM Cloud Pak for AIOps provides an SDK. This SDK supports custom user experience so that your custom integrations appear within the Cloud Pak for AIOps console integrations catalog. This SDK supports creating integrations for custom events, topology, logs, and tickets. In addition to ingesting tickets from custom ITSMs, the IBM Cloud Pak for AIOps SDK also supports ticket creation.

IBM Cloud Pak for AIOps also supports customizing the lifecycle of an event by using policies, which govern de-duplication, suppression, correlation, and incident creation. The policies can also be used to integrate with custom logic and enrichments by using IBM Tivoli Netcool/Impact. IBM Tivoli Netcool/Impact allows custom logic to be applied to a set of alerts or incidents. This logic can update the alert or incident itself, or run any logic based on the alert or incident. Runbooks can be associated with a defined set of alerts or incidents. These runbooks support custom logic run over SSH, REST or Ansible, and can be either manually or automatically run.

The detailed extensibility architecture resembles the following diagram:

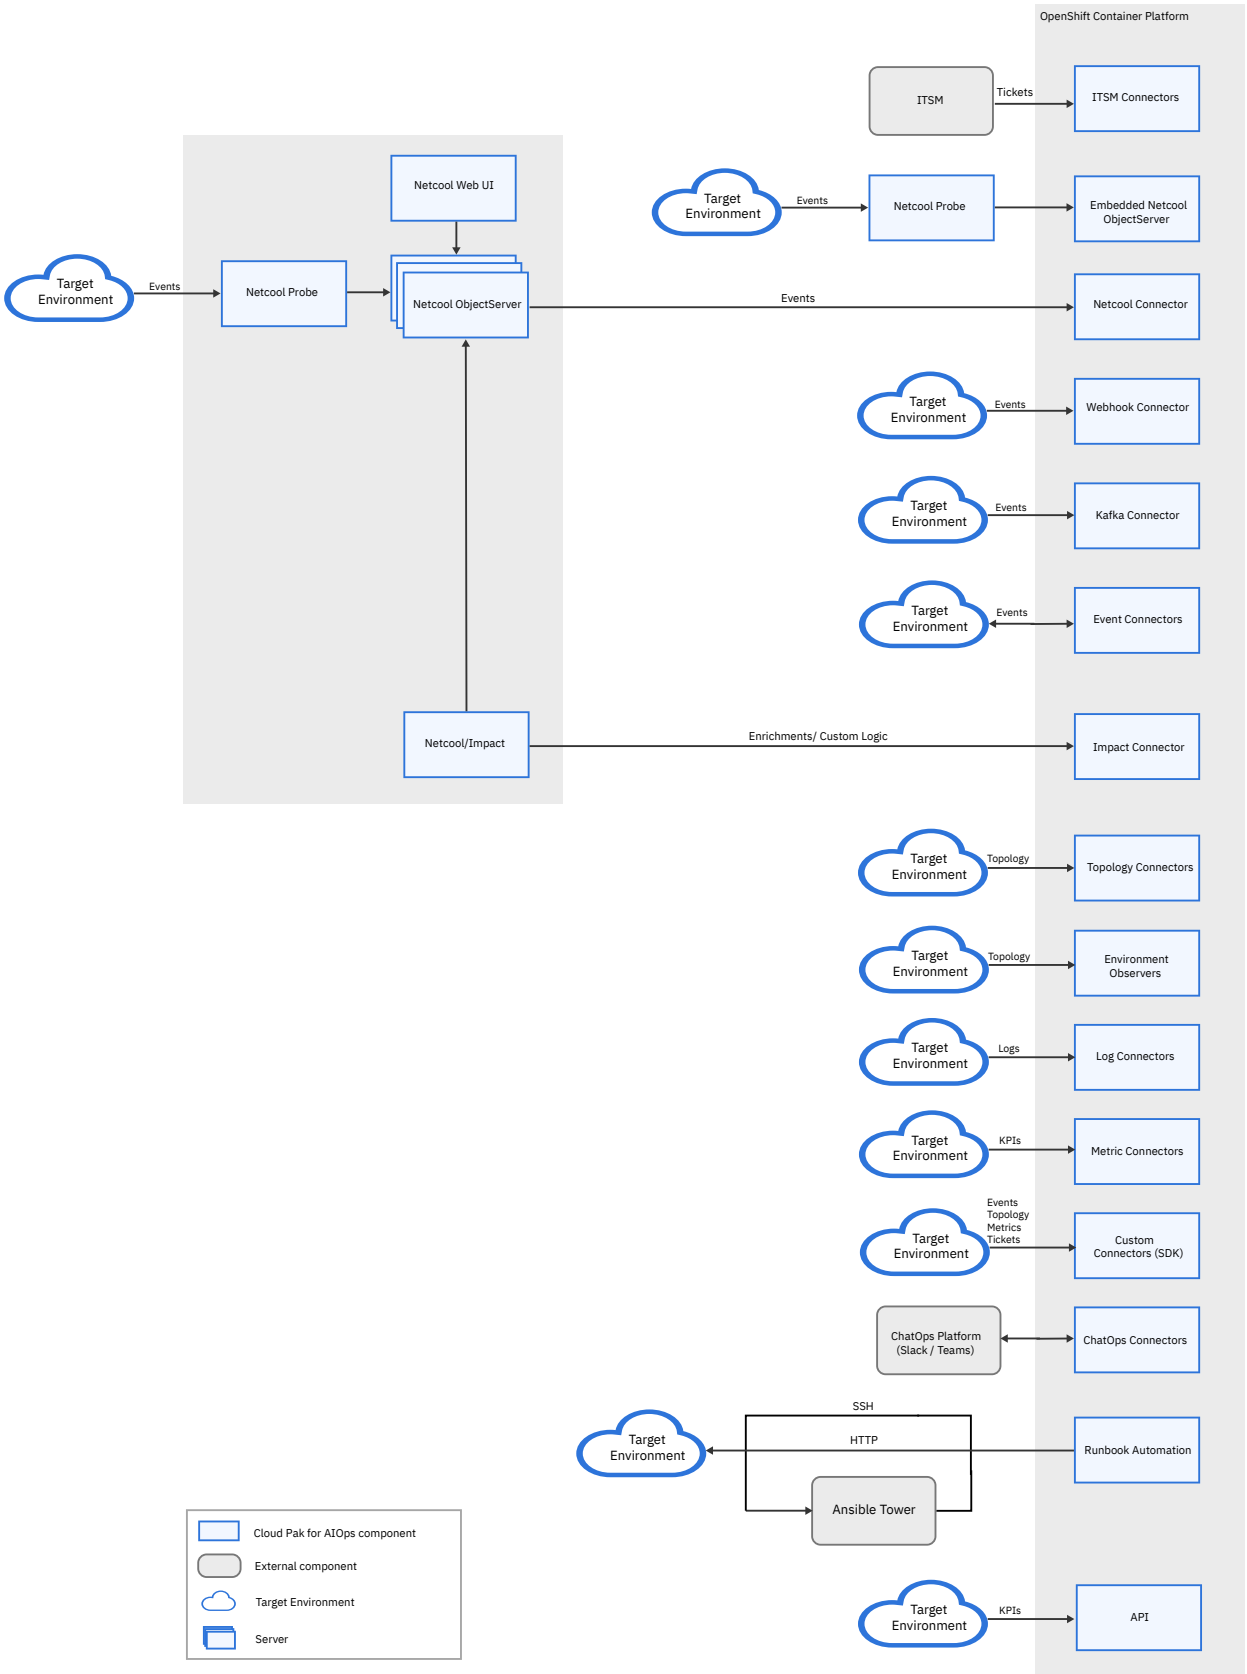

Figure. Extensibility

Infrastructure Automation architecture

Infrastructure Automation is a stand-alone module included within IBM Cloud Pak for AIOps. Infrastructure Automation brings together Infrastructure management and Managed services for an integrated, Infrastructure Automation capability for IT Operators.

The following sections illustrate how these capabilities come together in IBM Cloud Pak for AIOps:

- Deployment Architecture for Infrastructure Automation
- Deployment Architecture for IBM Cloud Pak for AIOps with Infrastructure Automation

Stand-alone Infrastructure Automation deployment architecture

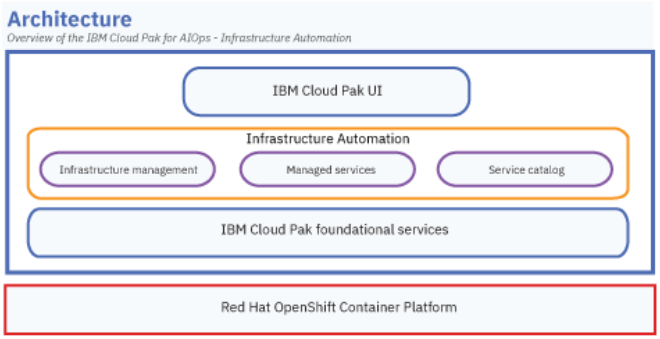

Figure. Infrastructure Automation architecture

Infrastructure automation is a stand-alone module within IBM Cloud Pak for AIOps. When you have a license for IBM Cloud Pak for AIOps, you are entitled to install and use Infrastructure Automation.

Infrastructure Automation consists of these components (formerly part of IBM Cloud Pak for Multicloud Management):

- Managed services and service catalog, previously called Terraform & Service Automation or IBM Cloud Automation Manager
- Infrastructure management, previously called IBM Red Hat CloudForms.

Managed services provide the capability to automate provisioning of infrastructure and virtual machine applications by using Terraform and Ansible. It includes supported versions of Terraform that works across multiple cloud environments with comprehensive IT workflow orchestration. Using out-of-box integration with Ansible, workflows can interconnect Terraform provisioning templates with Ansible playbooks for configuration management, fully supporting infrastructure-as-code (IaC) and GitOps best practices.The service catalog allows authors administrators to publish services and users to self-service provision infrastructure and applications.

Infrastructure Management delivers the insight, control, compliance, and automation enterprises need to address the challenges of managing hybrid cloud environments, which are far more complex than physical ones. This technology enables enterprises with existing virtual, baremetal, and cloud infrastructures to improve visibility, control and compliance, and those just starting hybrid cloud deployments to build and operate a well-managed hybrid cloud infrastructure.

Infrastructure Automation enables IT Operations and Site Reliability Engineer (SRE) teams to use infrastructure as code practices to drive IT velocity and shift to the left of operations. With this modernized infrastructure management, you can perform the following tasks:

- Shorten the time to provision infrastructure (VMs, Cloud Services, Kubernetes) across on-premises, private, and public clouds
- Create repeatable templates for common infrastructure requests
- Enable self-service catalogs to avoid manual responses to tickets
- Scale infrastructure automatically based on demand
- Support day-2 operations, which include automated compliance
- You can provision, run, and manage workloads on the infrastructure of your choice.

IBM Cloud Pak for AIOps Infrastructure Automation is installed on Red Hat® OpenShift® Container Platform. For more information about the supported versions of Red Hat OpenShift Container Platform, see Supported Red Hat OpenShift Container Platform versions.

Infrastructure Automation with IBM Cloud Pak for AIOps deployment architecture

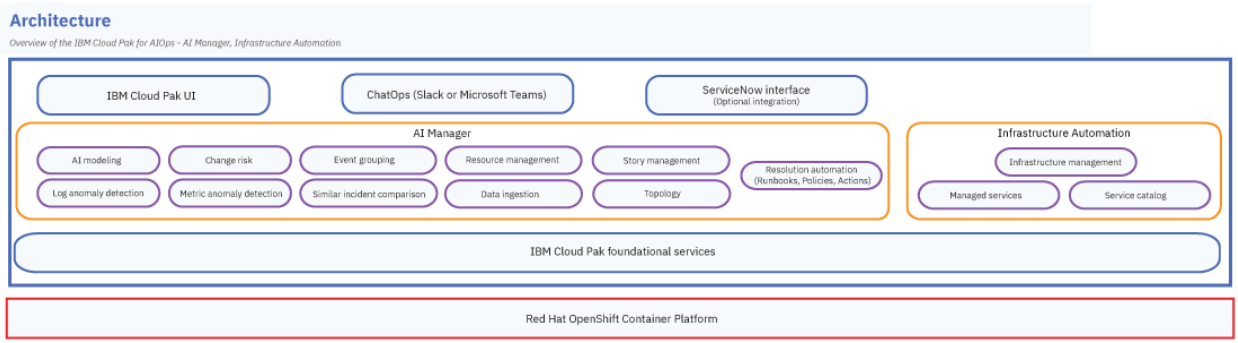

Figure. IBM Cloud Pak for AIOps with Infrastructure Automation architecture

Infrastructure automation can be used together with IBM Cloud Pak for AIOps to support use cases that require Terraform automation and service orchestration as part of the incident resolution process. Day 2 operations like changing the size of VMs, power management, or applying a patch are supported by Infrastructure Automation and can easily be accessed through a common console. They can also be automated through runbook actions by invoking Infrastructure Automation APIs. Both Infrastructure Automation and IBM Cloud Pak for AIOps integrate with ServiceNow and can be used together to calculate the risk score of infrastructure change requests.

Compliance

IBM Cloud Pak® for AIOps complies with the following security and privacy assessments, which can apply to all add-on services on IBM Cloud Pak for AIOps.

Customers are responsible for ensuring their own readiness for the laws and regulations that apply to them.

Customers are responsible for identifying and interpreting any relevant laws and regulations that might affect their users. Customers are also responsible for any actions their users might need to take to comply with these laws and regulations.

Customers must track whether personal information is present in their data. IBM Cloud Pak for AIOps is not aware of the presence of personal information in data imported from the client, such as log files. For more information about types of personal data that is processed by IBM Cloud Pak for AIOps, see Data Collection.

FIPS compliance

Federal Information Processing Standards (FIPS) are standards and guidelines that are issued by the National Institute of Standards and Technology (NIST) for federal government computer systems.

For more information, see Federal Information Processing Standards (FIPS).

FISMA compliance

For Federal Information Security Management Act (FISMA) level deployments, you need to follow the **FIPS compliance** and **Audit logging** sections.

For more information about FIPS compliance, see FIPS compliance.

For more information about Audit logging, see Audit logging.

For more questions around FISMA ready, contact your IBM Sales representative (or Business Partner).

GDPR

Customers are responsible for ensuring their own readiness for the laws and regulations, including the European Union General Data Protection Regulation.

For more information, see the following topics:

- Security and Privacy by Design (SPbD)
- Platform considerations for GDPR readiness

Federal Information Processing Standards (FIPS)

Federal Information Processing Standards (FIPS) are standards and guidelines that are issued by the National Institute of Standards and Technology (NIST) for federal government computer systems.

The standards are developed when compelling federal government requirements for standards, such as for security and interoperability, exist, but acceptable industry standards or solutions do not exist. Government agencies and financial institutions use these standards to ensure that products conform to specified security requirements.

Important: FIPs mode is not supported for deployments of IBM Cloud Pak for AIOps on Linux®.

Encryption with FIPS support enabled

When FIPS support is enabled, IBM Cloud Pak for AIOps uses cryptographic modules that are compliant with Level 1 of the Federal Information Processing Standard FIPS-140-2. Certificates that are used internally are encrypted by using FIPS-approved cryptography algorithms. FIPS-approved modules can optionally be used for the transmission of data. Traffic inside the IBM Cloud Pak for AIOps boundary is still secure, as traffic between nodes is automatically encrypted at the Red Hat® OpenShift® Container Platform level when TLS protection is enabled, while traffic inside a given node happens in-memory and does not leave the node.

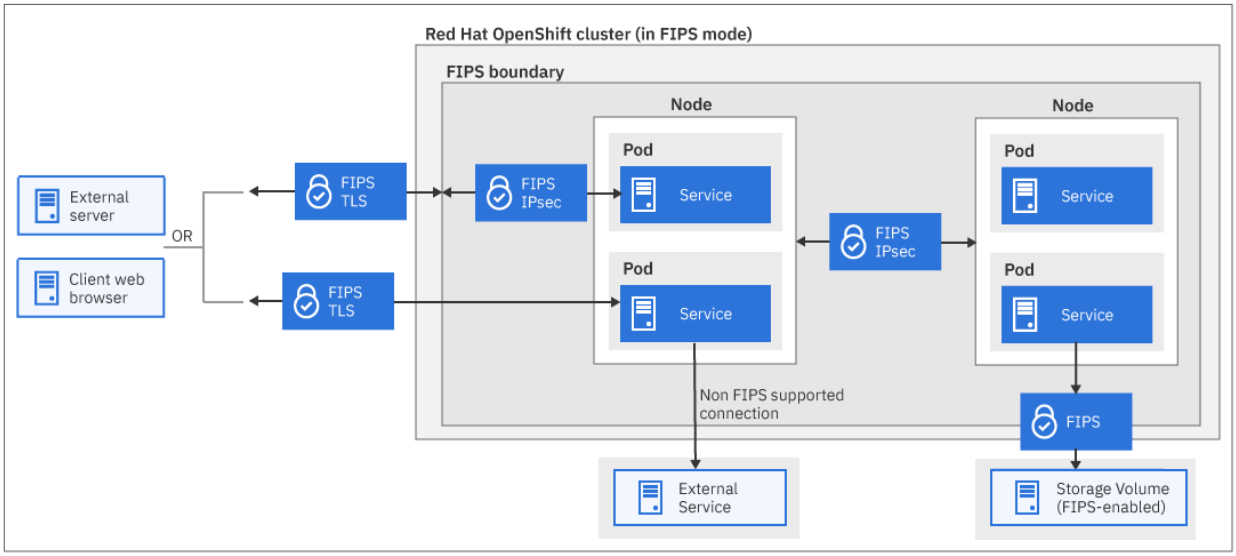

Figure. FIPs overview

FIPS (Federal Information Processing Standards) compliant encryption is validated for IBM Cloud Pak for AIOps services and components, including the IBM Cloud Pak foundational services that are used by IBM Cloud Pak for AIOps.

With FIPS enabled Data is FIPS encrypted at rest and inbound communications are FIPS encrypted. Outbound communications can support both FIPS enabled and non-enabled integrations. For FIPS enabled integrations, outbound integrations rely on the server to ensure FIPS ciphers are chosen. To ensure that integrations, including Observers, are FIPS enabled, an external service to mandate the use of FIPS compliant ciphers when negotiating encryption is required. Note that some restrictions to SSH actions accessing external endpoints apply when FIPS is enabled. For more information, see SSH algorithms.

Enabling FIPS support

To enable FIPS support, you must enable this support when you are installing Red Hat OpenShift Container Platform and IBM Cloud Pak for AIOps. For more information, see:

- IBM Cloud Pak for AIOps: Enabling Federal Information Processing Standards (FIPS) support
- Infrastructure Automation: Enabling Federal Information Processing Standards (FIPS) support

Enabling Federal Information Processing Standards (FIPS) support for IBM Cloud Pak for AIOps

Learn how to enable FIPS and run IBM Cloud Pak for AIOps on a FIPS-compliant system.

To enable support you need to install IBM Cloud Pak for AIOps on a Red Hat OpenShift Container Platform cluster that is running in a FIPS enabled mode. You also need to complete some tasks before you begin installing IBM Cloud Pak for AIOps on your cluster and complete other tasks while you are installing IBM Cloud Pak for AIOps. Depending on whether you plan to enable or set up some optional integrations, you might need to further complete tasks after your finish installing to ensure your integrations support FIPS.

Important:

- FIPs mode is not supported for deployments of IBM Cloud Pak for AIOps on Linux®.
- You can only enable FIPS support when you are installing. You cannot upgrade a non-FIPS enabled environment to a FIPS enabled environment. You also cannot backup an IBM Cloud Pak for AIOps from a non-FIPS enabled environment and restore it into a FIPS enabled environment. The remote kafka integration feature is not available on FIPS-compliant environments.

To enable FIPS support, complete the following tasks during your overall cluster and IBM Cloud Pak for AIOps installation:

1. Installing Red Hat OpenShift Container Platform and storage tasks required for compliance.

   These tasks must be completed when you are installing your Red Hat OpenShift Container Platform cluster and configuring your storage before you begin to install IBM Cloud Pak for AIOps on your OpenShift cluster.

2. Installing IBM Cloud Pak for AIOps tasks required for compliance

   While installing IBM Cloud Pak for AIOps you do need to complete some other required tasks to ensure you enable your environment to support FIPS.

3. Optional. Conditional tasks required for compliance

   Depending on the integrations that you plan to create for your IBM Cloud Pak for AIOps environment, you need to complete other tasks to enable FIPS support. For instance if you are integrating IBM Cloud Pak for AIOps with IBM Tivoli Netcool/OMNIbus, you need to configure the integration to support FIPS.

Installing Red Hat OpenShift Container Platform and storage tasks required for compliance

1. Enable FIPS support for your Red Hat OpenShift Container Platform cluster
2. Enable FIPS support for your storage

1. Enable FIPS support for your Red Hat OpenShift Container Platform cluster

You must enable FIPS support on your Red Hat OpenShift Container Platform cluster before you proceed with installing IBM Cloud Pak for AIOps. When you are installing IBM Cloud Pak for AIOps, the installation process automatically detects whether FIPS support is enabled on your Red Hat OpenShift Container Platform cluster. If FIPS is enabled on Red Hat OpenShift Container Platform, FIPS support is automatically enabled for IBM Cloud Pak for AIOps.

To enable FIPS for IBM Cloud Pak for AIOps, you must first enable FIPS support on your Red Hat OpenShift Container Platform cluster by completing the following tasks as part of installing Red Hat OpenShift Container Platform:

1. Enable FIPS mode on all of your nodes. For more information, see the Red Hat OpenShift Container Platform documentation about Support for FIPS cryptography
2. Install Red Hat OpenShift Container Platform in FIPS mode. For more information, see the Red Hat OpenShift Container Platform documentation about Installing a cluster in FIPS mode.

   Restriction: FIPS is supported only on x86_64 hardware.
3. Configure TLS protection for your node-to-node communication. Node-to-node communication must be TLS protected at all times.

   Recommended: Configure IPSec tunnels for communication between nodes in your cluster. IPSec is the validated and recommended method for implementing security across nodes for IBM Cloud Pak for AIOps. If you require a different method to secure your nodes, you can use your preferred method.

   With IPsec enabled, all network traffic between nodes on the OVN-Kubernetes Container Network Interface (CNI) cluster network travels through an encrypted tunnel. IPsec is disabled by default when you install OpenShift 4.x clusters. IPsec encryption can be enabled only during cluster installation and cannot be disabled after it is enabled.

   For more information about configuring IPsec encryption on Red Hat OpenShift Container Platform, see the Red Hat OpenShift Container Platform documentation about Configuring IPsec encryption.

2. Enable FIPS support for your storage

If your deployment's storage must be FIPS compliant, enable any FIPS settings and support for your chosen storage. Refer to your storage provider's documentation to ensure that your storage meets this requirement.

Red Hat® OpenShift® Data Foundation and FIPS

Red Hat® OpenShift® Data Foundation uses FIPS 140-2 certified cryptographic modules. You must use cluster wide encryption, and not encrypt persistent volumes individually. This is because Red Hat OpenShift Data Foundation persistent volume encryption is only available for block storage, and one of IBM Cloud Pak for AIOps's components, Zen, requires file storage. For more information, see the topic *Cluster-wide encryption* in the Red Hat OpenShift Data Foundation documentation.

Portworx and FIPS

Portworx uses FIPS 140-2 certified cryptographic modules. Portworx can encrypt each of the persistent volumes individually, or can encrypt the whole storage cluster. For more information, see the topic *Create encrypted PVCs* in the Portworx documentation.

Installing IBM Cloud Pak for AIOps tasks required for compliance

With your storage configured, continue your installation of IBM Cloud Pak for AIOps on your cluster.

Ensure that you complete the required installation tasks for compliance while you are installing IBM Cloud Pak for AIOps. These tasks must be completed while you are initially installing IBM Cloud Pak for AIOps.

For more information about, and instructions, for installing IBM Cloud Pak for AIOps, see:

- For more information about installing on specific cloud platforms, see Supported cloud environments for installing IBM Cloud Pak for AIOps.
- For more information about installing IBM Cloud Pak for AIOps overall, see Production installation. If you are installing a starter installation, see Starter installation.

Important: You must ensure that you have run the *Verify the installation* step for your chosen installation method, and that your deployment is healthy before you proceed.

Enable two-factor authentication (2FA)

To secure your environment with multi-factor authentication, you can configure single sign-on (SSO) between IBM Cloud Pak for AIOps and an identity provider that supports 2FA, such as IBM Security Verify. The identity provider's 2FA mechanism can then be used to authenticate IBM Cloud Pak for AIOps user login. Consult your chosen identity provider's documentation to setup 2FA.

For more information about IBM Security Verify, see IBM Security Verify.

Blog: A blog that provides an example of setting up single sign-on between a IBM Cloud Pak and IBM Security Verify is here: Tutorial: IBM Cloud Pak single sign-on (SSO) integration with IBM Security Verify.

Conditional tasks required for compliance

The following tasks are required depending on the integrations you plan to create for your IBM Cloud Pak for AIOps environment:

- IBM Cloud Pak for AIOps and Netcool integration compliance requirement: Enabling FIPS support

IBM Cloud Pak for AIOps and Netcool integration compliance requirement: Enabling FIPS support

If you plan to integrate IBM Cloud Pak for AIOps with IBM Tivoli Netcool/OMNIbus, you need to configure your integration to enable FIPS support. For more information, see Enabling Federal Information Processing Standards (FIPS) support for a Netcool integration.

Enabling Federal Information Processing Standards (FIPS) support for Infrastructure Automation

Learn how to enable FIPS and run Infrastructure Automation on a FIPS-compliant system.

To enable support you need to install Infrastructure Automation on a Red Hat OpenShift Container Platform cluster that is running in a FIPS enabled mode. You also need to complete some tasks before you begin installing Infrastructure Automation on your cluster and complete other tasks while you are installing Infrastructure Automation. Depending on whether you plan to enable or set up some optional integrations, you might need to further complete tasks after your finish installing to ensure your integrations support FIPS.

Important: You can only enable FIPS support when you are installing. You cannot upgrade a non-FIPS enabled environment to a FIPS enabled environment. You also cannot backup an Infrastructure Automation from a non-FIPS enabled environment and restore it into a FIPS enabled environment.

To enable FIPS support, complete the following tasks during your overall cluster and Infrastructure Automation installation:

1. Installing Red Hat OpenShift Container Platform and storage tasks required for compliance.

   These tasks must be completed when you are installing your Red Hat OpenShift Container Platform cluster and configuring your storage before you begin to install Infrastructure Automation on your OpenShift cluster.

2. Installing Infrastructure Automation tasks required for compliance

   While installing Infrastructure Automation you do need to complete some other required tasks to ensure you enable your environment to support FIPS:

3. Optional. Conditional tasks required for compliance

   Depending on the components that you plan to install in, or integrate with, your Infrastructure Automation environment, you need to complete other tasks to enable FIPS support. For instance if you plan to enable Managed services, you need to configure the deployment to support FIPS.

Installing Red Hat OpenShift Container Platform and storage tasks required for compliance

1. Enable FIPS support for your Red Hat OpenShift Container Platform cluster
2. Enable FIPS support for your storage

1. Enable FIPS support for your Red Hat OpenShift Container Platform cluster

You must enable FIPS support on your Red Hat OpenShift Container Platform cluster before you proceed with installing Infrastructure Automation. When you are installing Infrastructure Automation, the installation process automatically detects whether FIPS support is enabled on your Red Hat OpenShift Container Platform cluster. If FIPS is enabled on Red Hat OpenShift Container Platform, FIPS support is automatically enabled for Infrastructure Automation.

To enable FIPS for Infrastructure Automation, you must first enable FIPS support on your Red Hat OpenShift Container Platform cluster by completing the following tasks as part of installing Red Hat OpenShift Container Platform:

1. Enable FIPS mode on all of your nodes. For more information, see the Red Hat OpenShift Container Platform documentation about Support for FIPS cryptography

2. Install Red Hat OpenShift Container Platform in FIPS mode. For more information, see the Red Hat OpenShift Container Platform documentation about Installing a cluster in FIPS mode.

   Restriction: FIPS is supported only on x86_64 hardware.

3. Configure TLS protection for your node-to-node communication. Node-to-node communication must be TLS protected at all times.

   Recommended: Configure IPSec tunnels for communication between nodes in your cluster. IPSec is the validated and recommended method for implementing security across nodes for IBM Cloud Pak for AIOps. If you require a different method to secure your nodes, you can use your preferred method.

   With IPsec enabled, all network traffic between nodes on the OVN-Kubernetes Container Network Interface (CNI) cluster network travels through an encrypted tunnel. IPsec is disabled by default when you install OpenShift 4.x clusters. IPsec encryption can be enabled only during cluster installation and cannot be disabled after it is enabled.

   For more information about configuring IPsec encryption on Red Hat OpenShift Container Platform, see the Red Hat OpenShift Container Platform documentation about Configuring IPsec encryption.

2. Enable FIPS support for your storage

If your deployment's storage must be FIPS compliant, enable any FIPS settings and support for your chosen storage. Refer to your storage provider's documentation to ensure that your storage meets this requirement.

Red Hat® OpenShift® Data Foundation and FIPS

Red Hat® OpenShift® Data Foundation uses FIPS 140-2 certified cryptographic modules. You must use cluster wide encryption, and not encrypt persistent volumes individually. This is because Red Hat OpenShift Data Foundation persistent volume encryption is only available for block storage, and one of IBM Cloud Pak for AIOps's components, Zen, requires file storage. For more information, see the topic *Cluster-wide encryption* in the Red Hat OpenShift Data Foundation documentation.

Portworx and FIPS

Portworx uses FIPS 140-2 certified cryptographic modules. Portworx can encrypt each of the persistent volumes individually, or can encrypt the whole storage cluster. For more information, see the topic *Create encrypted PVCs* in the Portworx documentation.

Installing Infrastructure Automation tasks required for compliance

With your storage configured, continue your installation of Infrastructure Automation on your cluster.

Ensure that you complete the required installation tasks for compliance while you are installing Infrastructure Automation. These tasks must be completed while you are initially installing Infrastructure Automation.

For more information about, and instructions, for installing Infrastructure Automation overall, see Installating Infrastructure Automation.

Enable two-factor authentication (2FA)

To secure your environment with multi-factor authentication, you can configure single sign-on (SSO) between Infrastructure Automation and an identity provider that supports 2FA, such as IBM Security Verify. The identity provider's 2FA mechanism can then be used to authenticate Infrastructure Automation user login. Consult your chosen identity provider's documentation to setup 2FA.

For more information about IBM Security Verify, see IBM Security Verify.

Blog: A blog that provides an example of setting up single sign-on between a IBM Cloud Pak and IBM Security Verify is here: Tutorial: IBM Cloud Pak single sign-on (SSO) integration with IBM Security Verify.

Conditional tasks required for compliance

The following tasks are required depending on the components that you plan to enable for your Infrastructure Automation environment:

- Deploy Infrastructure Automation - Managed services in FIPS mode

Deploy Infrastructure Automation - Managed services in FIPS mode

If you need to deploy Managed services in your FIPS enabled environment, you can deploy the component after you complete your install by editing the **`IAConfig`** settings. This task can be completed after you complete your initial installation, but needs to be completed when you are initially deploying Managed services.

1. Use the OpenShift (**`oc`**) CLI to log in to your OpenShift cluster and switch to the project (namespace) where Infrastructure Automation is installed.
2. Run the following command to open the **`IAConfig`** configuration for editing:

   ```
   oc -n <namespace> edit IAConfig
   ```

   Where **`<namespace`** is the project (namespace) where Infrastructure Automation is installed.
3. Search for the **`spec`** section and edit the configuration to include the settings to deploy Managed services (**`ibm-management-cam-install`**) in FIPS mode (**`enableFIPS: true`**). Your updated configuration for deploying managed services can resemble the following example spec:

   ```
   spec:
       imagePullSecret: ibm-entitlement-key
       infraAutoComposableComponents:
       - enabled: true
         name: ibm-management-im-install
         spec: {}
       - enabled: true
         name: ibm-management-cam-install
         spec:
           manageservice:
             global:
               enableFIPS: true
             license:
               accept: true
       license:
         accept: true
   ```

Enabling Federal Information Processing Standards (FIPS) support for an IBM Tivoli Netcool/OMNIbus integration

If you plan to integrate IBM Cloud Pak for AIOps with IBM Tivoli Netcool/OMNIbus, you can configure your integration to enable support for Federal Information Processing Standards (FIPS).

Prerequisites

- You must have an existing FIPS-compliant installation of IBM Cloud Pak for AIOps. You cannot enable FIPS support for the integration on a noncompliant system.

  For more information about installing IBM Cloud Pak for AIOps to be FIPS-compliant, see Enabling support for Federal Information Processing Standards (FIPS).

- You must have an existing FIPS-compliant installation of IBM Tivoli Netcool/OMNIbus.

Procedure

To enable FIPS mode in IBM Tivoli Netcool/OMNIbus, complete the following steps on the host where IBM Tivoli Netcool/OMNIbus (on premises ObjectServer) is running:

1. Stop the ObjectServer pair and the IBM Tivoli Netcool/OMNIbus bidirectional gateway.

   - To stop the ObjectServer, complete the following steps:

     - Open the ObjectServer SQL prompt:

       ```
       $OMNIHOME/bin/nco_sql -server <OS_NAME> -user root -password <plain-text-pwd>
       ```

     - On the SQL prompt, run the following command:

       ```
       > alter system shutdown;
       > go
       ```

     Note: After you enter **go**, the SQL prompt disconnects as the ObjectServer is exiting.

   - To stop the bidirectional gateway, run the following command:

     ```
     kill -15 <pid>
     ```

     where **pid** is Process ID.

     Note: Use the **ps -ef | grep nco_g_objserv_bi** command to get the gateway's pid.

2. Enter the following information in the properties file of both the ObjectServers:

   ```
   PasswordEncryption   : 'AES'
   ConfigKeyFile        : '<key_file>'
   ```

   Note: To generate the key file, run the following command on the host:

   ```
   $OMNIHOME/bin/nco_keygen -o <key_file> -l 256
   ```

3. Start the ObjectServer pair and update the same FIPS-compliant password for the root user in each ObjectServer.

   1. To start the ObjectServer, run the following command:

      ```
      $OMNIHOME/bin/nco_objserv -name <OS_NAME> -propsfile <objectserver-properties-file> &
      ```

   2. To open the ObjectServer SQL prompt, run the following command:

      ```
      $OMNIHOME/bin/nco_sql -server <OS_NAME> -user root -password <plain-text-pwd>
      ```

   3. To alter root password, run the following SQL command:

      ```
      > alter user 'root' set password '<plain_text_pwd>';
      > go
      ```

   4. To verify that the Passwd column contains AES-encrypted passwords with 24 characters, run the following SQL command:

      ```
      > select UserName,Passwd from security.users;
      > go
      ```

4. Generate the encrypted IBM Tivoli Netcool/OMNIbus root password by using the ConfigKeyFile.

   - To create the encrypted password, run the following command:

     ```
     $OMNIHOME/bin/nco_aes_crypt -c AES_FIPS -k string -o <encrypted_file> -k <key_file> <root_plain_text_pwd>
     ```

     Note: For more information about generating a key in a key file, see Generating a key in a key file.

5. Apply the configurations in the properties file of the bidirectional gateway:

   ```
   Gate.ObjectServerA.Password  : '<encrypted_root_pwd>'
   Gate.ObjectServerB.Password  : '<encrypted_root_pwd>'
   ConfigKeyFile                : '<key_file>'
   ```

6. Place the following files in the **$NCHOME/etc/security** directory to enable FIPS mode in IBM Tivoli Netcool/OMNIbus:

   - **fips.conf**:

```
SP800_131MODE=TRUE
TLS12_ONLY=TRUE
```

- `sslciphers.conf`:

```
sslv3_remove=_
tls10_remove=_
tls11_remove=_
tls12_remove="TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_128_CBC_SHA,TLS_RSA_WITH_AES_256_CBC_SHA,TLS_RSA_WI
TH_AES_128_GCM_SHA256,TLS_RSA_WITH_AES_256_GCM_SHA384,TLS_RSA_WITH_AES_128_CBC_SHA256,TLS_RSA_WITH_AES_256_CBC_
SHA256"
```

7. Start the ObjectServer pair and the bidirectional gateway.

   - To start the ObjectServer, run the following command on the host:

     ```
     $OMNIHOME/bin/nco_objserv -name <OS_NAME> -propsfile <objectserver-properties-file> &
     ```

     For example,

     ```
     $OMNIHOME/bin/nco_objserv -name AGG_P -propsfile $OMNIHOME/etc/AGG_P.props &
     ```

   - To start the bidirectional gateway, run the following command on the host:

     ```
     $OMNIHOME/bin/nco_g_objserv_bi -propsfile <gateway-properties-file> &
     ```

     For example,

     ```
     $OMNIHOME/bin/nco_g_objserv_bi -propsfile $OMNIHOME/etc/AGG_GATE.props &
     ```

Audit logging

The audit logging capabilities within IBM Cloud Pak for AIOps provide you with the capability to track changes that were made to your system, when the changes were made, and by whom. The recorded audit logs include the record of actions that were completed or attempted by users or services of your IBM Cloud Pak for AIOps system. This auditing helps you with ensuring accountability, trackability, and regulatory compliance for data access, modification, and security within your IBM Cloud Pak for AIOps environment.

If you require that your environment supports the Federal Regulatory Compliance Standard (FISMA), you need to ensure that your environment has audit logging.

What is audited in IBM Cloud Pak for AIOps?

IBM Cloud Pak for AIOps capabilities audit the following types of actions, which can return, manage, manipulate, or access sensitive data:

- Successful and unsuccessful login attempts
- Authentication checks
- Authorization checks
- Account management events
- Object access
- Policy changes
- Privileged functions
- Data access
- Data changes
- Process tracking
- System events
- Administrator activities
- Permission changes

For more information and details about what is logged for IBM Cloud Pak for AIOps, see Logged actions and data for auditing.

How do you configure audit logging?

Application logging

For IBM Cloud Pak for AIOps capabilities, audit logging is configured and enabled by default.

For Infrastructure Automation, you need to enable audit logging during installation. For the list of audit-related installation parameters, see Installation parameters.

IBM Cloud Pak for AIOps uses the IBM Cloud Pak foundational services Identity Management (IM) and Integrated UI (Platform UI **Zen**) services. For more information about auditing logging for these services, see Auditing IM service.

Platform logging

If you have a deployment of IBM Cloud Pak for AIOps or Infrastructure Automation on Red Hat OpenShift, then you must configure audit logging for platform level calls. For Red Hat OpenShift Container Platform audit logging, see the Red Hat OpenShift Container Platform documentation Viewing audit logs.

If you have a deployment of IBM Cloud Pak for AIOps on Linux®, then platform logging is enabled by default. Logs are stored in the **aiopsctl** directory on each control plane node. Logs are retained for up to 30 days, with a maximum total log size of 1GB.

How do you view a record of audit logs?

- For IBM Cloud Pak for AIOps capabilities, the audit logs for all recorded actions are written to standard output **stdout** in JSON format.

  Viewing audit logs for a deployment on Red Hat OpenShift

  You can view an audit log for a pod by using the **oc logs** command.

  If you want to, or need to, view multiple audit logs, you can ingest and view the logs with a log aggregator, such as the logging subsystem for Red Hat OpenShift. With this logging subsystem, you can aggregate all the logs from your OpenShift Container Platform cluster, including IBM Cloud Pak for AIOps audit logs. You can then view the logs with the Kibana web console. For more information about the logging subsystem for Red Hat OpenShift, see the Red Hat OpenShift documentation Installing the logging subsystem for Red Hat OpenShift.

  You can also use other services for log aggregation, such as Falcon Logscale or an Elasticsearch, Logstash, and Kibana (ELK) stack.

  Run the following command to view the API audit logs, which are stored in the **ibm-nginx** pod logs:

  ```
  oc logs -l component=ibm-nginx -c ibm-nginx-container | grep eventTime
  ```

  Viewing audit logs for a deployment on Linux

  To review the audit logs, run the following command on a control plane node:

  ```
  ls ~/.aiopsctl/logs/
  ```

  Example output:

  ```
  aiopsctl.log  audit-2024-09-18T15-17-26.791.log  audit-2024-09-18T16-11-15.367.log  audit.log
  ```

- For Infrastructure Automation, Infrastructure management appliances use the systemd logger, journalctl for audit logging. Appliances that run UI workers log the UI requests. Appliances that run the web services role log the API requests.

  Logging for podified deployments use the standard output **stdout** logger. You can view these logs through an **oc logs** command. To view a log, you need to specify the correct UI or web service pod.

What is included in an audit log

The audit log messages for a recorded action or event in IBM Cloud Pak for AIOps include information to identify the action or event that occurred, when the action or event occurred, the action or event source and outcome, and the identity of the associated user or service.

For the more information about what is included in audit log messages, including example messages, see Audit log messages.

Logged actions and data for auditing

For audit logging, IBM Cloud Pak for AIOps capabilities log information about numerous user interactions, system processes, and events, which can each return, manage, manipulate, or access sensitive data. The following lists, detail the actions and data that is recorded in audit logs.

- IBM Cloud Pak for AIOps
- Infrastructure Automation

IBM Cloud Pak for AIOps

IBM Cloud Pak for AIOps capabilities audit the following types of actions, which can return, manage, manipulate, or access sensitive data:

- Successful and unsuccessful login attempts
- Authentication checks These checks run when a user attempts to log in to the UI. The record for these checks includes whether the attempt was successful. These checks do not include checks for internal system service-to-service authentication actions, such as when a secret is used to authenticate to a database.
- Authorization checks These checks run to determine whether a user has the required role and permission for completing an action.
- Account management events These events include actions for adding, changing, removing users, and managing credentials and role-based access control.
- Object access This access includes the access of data objects through the IBM Cloud Pak for AIOps UI or APIs.
- Policy changes The auditing of these changes includes policy changes for the management of user access controls, such as access policies. This auditing does not include event suppression policies.
- Privileged functions This auditing records changes for administrator access controls, such as access policies and their ability to run administrator-level tasks.
- Data access This auditing records the read-access any of data, such as viewing data on a UI page. The viewing of the following data through the UI or API is audited:
  - Integrations
    - Viewing the set of configured integrations
    - Viewing the status of an integration
    - Viewing the configuration of an integration

    - AIOps Insights
        - Viewing aggregate usage information, such as information about the number of resources, events, incidents, runbooks
    - AI Models
        - Viewing the set of configured AI model definitions
        - Viewing a AI model definition's status
        - Viewing a AI model definition's configuration
        - Viewing the status and details of an AI model version
    - Resources
        - Viewing the list of resources, resources groups, or applications
        - Searching resources, resource groups, or applications
        - Viewing the configuration of a resource, resource group, or application
        - Viewing the topology of an application
    - Incidents and alerts
        - Viewing the list of incidents or alerts
        - Viewing incident or alert details
    - Automations
        - Viewing the list of policies
        - Viewing a specific policy
        - Viewing the list of runbooks
        - Viewing a specific runbook
        - Viewing the list of automation actions
        - Viewing a specific automation action
- Data changes This auditing records actions for creating or changing data. Changes to the following types of data are recorded:
    - Integrations
        - Creating or editing an integrations
    - AI Models
        - Creating or editing an AI model definition
        - Creating an AI model version through AI training
        - Editing the state of an AI model version
    - Resources
        - Creating or editing a resource, resource group, or application
    - Alerts & Incident
        - Changing the state of an alert, including by policies
        - Editing an alert journal
        - Changing the incident details, such as the incident owner or state
    - Automations
        - Creating or editing a policy, runbook, or action
- Data deletions This auditing records the deletion of the following types of data:
    - Integrations
        - Deleting an integrations
    - AI models
        - Deleting an AI model definition or AI model version
    - Resources
        - Deleting a resource, resource group, or application
    - Automations
        - Deleting a policy, runbook, or action
- Process tracking This auditing records the action that caused a policy to run. A policy action is not caused by a user interaction. Instead, the action is caused by the policy service, with the data object for which the policy is applied being the target. Audit logs record an entry (policy ID, ID of the entity the policy ran on) whenever a policy runs due to one of the following actions occurring:
    - aiops.ibm.com/trigger/event-received
    - aiops.ibm.com/trigger/alert-pre-create
    - aiops.ibm.com/trigger/alert-created
    - aiops.ibm.com/trigger/alert-pre-update
    - aiops.ibm.com/trigger/alert-pre-delete
    - aiops.ibm.com/trigger/incident-pre-create
    - aiops.ibm.com/trigger/incident-created
    - aiops.ibm.com/trigger/incident-pre-update
    - aiops.ibm.com/trigger/incident-pre-delete

  One or more of these actions can occur when one of the following processes run:
    - Alert suppression through a policy
    - Alert creation through a policy
    - Correlating an alert to another alert through a policy
    - Creating an incident through a policy
    - Assigning or running an action through the UI, API, or policy
    - Assigning or running a runbook through the UI, API, or policy
    - Running an Ansible, HTTP or SSH automation action on an external system
    - Creating or updating an incident ticket through a policy
    - Creating or updating a ChatOps message through a policy
    - Determining a change risk score through a policy
    - Updating a change ticket with a change risk score through a policy
    - Providing model feedback
- System events This auditing records system and maintenance tasks that are not included within the preceding categories, such as the following actions:
    - Back up and restore

- Administrator activities This auditing records activities that require a user with an administrator role, including the following activities:
    - Integrations
        - Viewing the set of configured integrations
        - Viewing the status of an integrations
        - Viewing the configuration of an integrations
        - Creating, editing, or deleting an integrations
    - AI models
        - Viewing the set of configured AI model definitions
        - Viewing a AI model definition's status
        - Viewing a AI model definition's configuration
        - Viewing the status and details of an AI model version
        - Creating, editing, or deleting an AI model definition
        - Creating, editing, or deleting an AI model version
    - Resources
        - Viewing the configuration of a resource, resource group, or application
        - Creating, editing, or deleting a resource, resources group, or application
    - Automations
        - Viewing a specific runbook
        - Viewing the list of automation actions
        - Viewing a specific automation action
        - Creating, editing, or deleting a policy, runbook, or action
- Permission changes Records of the changes and management of user permissions.

Infrastructure Automation

Infrastructure Automation capabilities audit the following types of actions and data:

- Infrastructure management
- Managed services

Infrastructure management

Infrastructure management audits UI and API interactions. This logging includes UI privilege checks, invalid session requests through a session timeout or reloading a page after a user logs out.

Managed services

Managed services logging includes records for the following actions:

- Logging in or out of the UI
- Creating, editing, or deleting a cloud connection
- Creating, editing or deleting a DataTypes in shared parameters
- Creating, editing or deleting a DataObjects in shared parameters
- Adding or editing namespace for a DataObjects in shared parameters
- Creating, editing or deleting dynamic parameters
- Deploying a stack
- Modifying an existing stack (plan and apply)
- Modifying an existing stack record attributes
- Destroying or deleting a stack
- Creating, deleting an IAAS resource task
- Creating, editing, or deleting an IAAS resource settings
- Creating, editing, or deleting a template
- Creating, editing, or deleting a template version
- Creating, update or deleting provider engine
- Creating, update or deleting providers plugins
- Creating, editing, duplicating, retiring or deleting a service
- Adding or editing namespaces for a service
- Creating or deleting a service plan
- Creating, editing, or deleting a service category
- Adding or editing a service version
- Publishing, retiring, unretiring, duplicating, or deleting a service version
- Pushing to, or Pulling from, a Git service version
- Deploying a service-instance
- Resuming or Retrying a service-instance
- Terminating or deleting a service-instance
- Invoking or terminating a bind action for a service-instance
- Invoking a custom action for a service-instance
- Generating update plan for a service-instance
- Updating a service-instance
- Getting Upgrade or Downgrade service versions for a service-instance
- Generating service version change plan for a service-instance
- Running service version change for a service-instance
- Creating, editing, or deleting an independent custom action category
- Creating, editing, deleting, or invoking independent custom action
- Set or Unset namespace for independent custom action
- Lock or Unlock an independent custom action

- Creating, editing, or deleting an SMTP connection
- Adding or Deleting subscription store configuration

Audit log messages

For IBM Cloud Pak for AIOps capabilities, the log message entries for a recorded action or event include information to identify the action or event that occurred, when the action or event occurred, the action or event source and outcome, and the identity of the associated user or service.

Note: Some audit-specific fields, such as the username, are part of a generic message field and are not broken out into a dedicated field.

For Infrastructure Automation Infratructure management, the audit log messages include the HTTP method, username, role, request ID, session ID, requested URL path, and details for any specific privilege checks.

For example, a request to load the dashboard at `/dashboard/show` logs the `show` action and the privilege check (`dashboard_view`) for that page. Some pages can have multiple privilege checks as the UI determines what data a user can view or act upon.

Log messages

Log messages can include the following details:

Table. Log message details

Field Name	Required (IBM Cloud Pak for AIOps)	Required (UI)	Required (API)	Description	Example	Jsonpath in logging (API)
logType	Yes	Yes	Yes	An indicator of the fact that this is an audit message. This is used for allowing easy identifying audit versus other log messages. This is always set to `audit`	`audit`	
id	No	No	No	The unique ID for the request	`271bfd04-a625-48ec-b33c-c7e9958f646c`	
initiator.id	Yes	Yes	Yes	ID of the identity or user that initiated the action.	User IAM ID API key	`.request.headers.audit-initiator-id`
initiator.name	Yes	Yes	Yes	Name of the identity or user that initiated the action.	username for users `system` `policy-service` for policy actions.	`.request.headers.audit-initiator-name`
initiator.typeURI	Yes	Yes	Yes	CADF URI description of the initiator type. For UI audit logs, this URI is most likely the user.	`security/account/user` for cookie or user initiated actions `security/account/service` or `security/account/admin` for apikey or service or system initiated actions.	`.request.headers.audit-initiator-typeuri`

initiator.credential.type	Yes	Yes	Yes	Type of authentication provided by the initiator. For UI audit logs, the value is often `cookie`.	`token`
					`user`
					`apikey`
					`cookie`
					`unknown`
						`.request.headers.audit-initiator-credential-type`

initiator.credential.identity_status	No	No	No	Status of the identity authentication for the initiator or user.	`Confirmed`
					`Denied`
					`Unknown`
						`request.headers.audit-initiator-credential-identity_status`

initiator.host.address	No	No	No	Source IP from where the request originated.	IP address of the Red Hat OpenShift Load Balancer.	`.client_ip`
initiator.host.agent	N/A	N/A	Yes	The client type of API request	`curl/7.61.1` `HTTPie/2.4.0`	`.request.headers.user-agent`
target.name	Yes	Yes	Yes	The name of the service that is accepting the request. For UI audit logs, this is populated as an environment variable in the deployed UI server (`AUDIT_SERVICE_NAME`)	`service; resource` `api.acme.com`	`.service.host`
target.id	Yes	No	Yes	CRN of the service accepting this request. For UI audit logs, this value is populated as an environment variable in the deployed UI server (`AUDIT_SERVICE_CRN`)	`b7dd7db9-45f2-4c05-abb5-01466c2abcdf`	`.service.host`
target.typeURI	Yes	No	Yes	This is a constant value that is stored in `AUDIT_RESOURCE_CADF_URI`.	`service` for HTTP/Ansible `system` for Script	`service`

Field Name	Required (IBM Cloud Pak for AIOps)	Required (UI)	Required (API)	Description	Example	Jsonpath in logging (API)
requestData.path	Yes	Yes	Yes	The request path, such as the API, which indicates the specific request being made of the service.	`api/v2/inventories/d220b490-7c75-11ed-b6f3-23388646a3b9`	`.request.uri`

requestData.type	No	Yes	No	The request method, which indicates whether this is a view, create, update, or delete.	`GET`
					`PUT`
					`DELETE`
					`POST`
						`.request.method`

requestData.actionId	No	No	No	Automation/Action ID.	`c6ccc725-3e54-493d-a114-de5130e7c64b`	

action	Yes	No	Yes	The action that triggers an event. This is superceded by `requestData.method`.	`create`
					`update`
					`delete`
					`deploy`
					`authenticate`
						`view`
						`create`

outcome	Yes	Yes	Yes	Was the action succesful?	`success`
					`pending`
					`failure`
					`unknown`
						`success`

reason.reasonCode	Yes	Yes	Yes	The HTTP response code of the result.	`200` for success.	`.response.status`
reason.reasonSize	Yes	Yes	Yes	The HTTP response size of the result.	`116`	`.response.size`
reason.message	Yes	No	Yes	The HTTP response message explaining the result. For API, Follow Format 'action [custom data] [outcome]'	`OK` for success.	`view success`
eventTime	Yes	Yes	Yes	The time, date, and time zone of the event in Coordinated Universal Time (UTC)	`2022-11-14T11:28:54.753Z`	`.started_at`
attachments.content.correlation_id	No	No	No	An optional ID that can be used to correlate multi-part audit logs.	`cccccc-eeee-dddd-aaaa-bbbbbbbbbbbb`	

Examples

Example: Policy action audit log

The following message is an example audit log message for policy actions:

```
{
  "eventTime": "2024-05-21T15:22:23+00:00",
  "initiator": {
    "credential.type": "token",
    "id": "1000331001",
    "name": "cpadmin",
    "typeURI": "security/account/user"
  },
  "logType": "audit",
  "reason": {
    "reasonCode": "200"
  },
  "requestData": {
    "path": "/aiops/api/issue-resolution/v1/alerts",
    "type": "GET"
  },
  "target": {
    "name": "cpd-cp4waiops.example.com",
    "typeURI": "service"
  }
}
```

Example: UI audit log

The following JSON is an example of audit log message for UI pod:

```
{
  "logType": "audit",
  "initiator": {
    "id": "1000331001",
    "name": "cpadmin",
    "typeURI": "security/account/user",
    "credential": {
      "type": "cookie",
      "identity_status": "Confirmed"
    },
  },
  "requestData": {
    "path": "/aiops/homepage/api/application",
    "type": "GET"
  },
  "target": {
```

```
    "name": "--"
  },
  "outcome": "success",
  "reason": {
    "reasonCode": 200,
    "message": "OK"
  },
  "eventTime": "2024-11-01T03:13:06.747Z"
}
```

Example: Automation audit log

The following JSON is an example of automation audit log message:

```
{
"logType": "audit",
"attachments": {
  "content": {
  "correlation_id": "c8084070-9aca-11ef-a826-21984ee4e499",
  "context": "runbook:302457ed-cd0d-4634-b5df-ae332562fcd4,runbookinstance:c8cb3d062ab8d7b0783cbf47e45761d5"
},
"type": "application/json"
},
"initiator": {
  "id": "ld",
  "name": "user123@mymail.com",
  "typeURI": "security/account/user"
},
"level": 30,
"target": {
  "name": "mytarget@example.com",
  "typeURI": "service"
},
"requestData": {
  "path": "/json",
  "type": "GET",
  "actionId": "95735585-61fa-4544-a865-57652188dd00",
  "action": "http.execute"
},
"eventTime": "2024-11-04T16:35:20.326Z",
"reason": {
  "reasonCode": 200,
  "message": "OK"
},
"outcome": "success",
"msg": "Security Audit Log Record",
"time": "2024-11-04T16:35:20.883Z",
"v": 0
}
```

Example: API audit log

The following JSON is an example of API audit log message:

```
{
    "outcome": "success",
    "eventTime": "2023-02-03T06:13:17Z",
    "reason": {
        "reasonSize": 438,
        "message": "view success",
        "reasonCode": 200
    },
    "initiator": {
        "name": "admin",
        "host": {
            "agent": "curl/7.61.1",
            "address": "10.9.5.41"
        },
        "id": "1000330999",
        "typeURI": "security/account/user",
        "credential": {
            "idenity_status": "Confirmed",
            "type": "token"
        }
    },
    "requestData": {
        "type": "GET",
        "path": "/aiops/api/application-manager/topology-rest-observer/v1/healthcheck"
    },
    "target": {
        "id": "aiops-topology-rest-observer.katamari.9104.svc",
        "typeURI": "service",
        "name": "aiops-topology-rest-observer.katamari.9104.svc"
    },
    "action": "view"
}
```

Example: Infrastructure Management audit log

The following example log shows an audit log that includes log entries for successful requests, logon failures, requests that failed due to missing product features, and an invalid (stale) session.

```

Enable Auditing for Infrastructure Automation Managed services

You can enable auditing for Infrastructure Automation Managed services.

1. Enable auditing during installation or post-installation by updating the **iaconfig** configuration. You can update the configuration by using the following command.

   ```
   oc -n cp4aiops edit iaconfig
   ```

   - Find the **spec** and add **manageservice** to its **spec** section. For example:

     ```
     spec:
       infraAutoComposableComponents:
        name: ibm-management-cam-install
        spec:
          manageservice:
          global:
           audit: true
           license:
             accept: true
     license:
       accept: true
     ```

2. To configure the IBM Cloud Pak foundational services for receiving audit logs, see Architecture for Audit logging version 4.6.

Security and Privacy by Design (SPbD)

Security and Privacy by Design (SPbD) at IBM® is an agile set of focused security and privacy practices, including threat models, privacy assessments, security testing, and vulnerability management.

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of IBM Cloud Pak® for AIOps that you can configure, and aspects of the product's use, to consider for GDPR readiness. This information is not an exhaustive list, due to the many ways that customers can choose and configure features, and the product can be used in itself and with third-party applications and systems.

IBM developed a set of SPbD processes and tools that are used by all of its business units. For more information about the IBM Secure Engineering Framework (SEF) and SPbD, see the IBM Redbooks Security in Development - The IBM Secure Engineering Framework (available in PDF format).

IBM also provides information about the features of IBM® Netcool® Operations Insight® that you can configure, how to use the product securely, and what to consider to help your organization with GDPR readiness. For more information, see Platform considerations for GDPR readiness.

As part of being secure by default, all intra-product communication is encrypted with TLS on deployments of IBM Cloud Pak for AIOps on Linux® and Red Hat® OpenShift® Container Platform. In addition, both deployment options adhere to best practices such as running containers as non-root. Deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift Container Platform also take advantage of additional security that is provided by Red Hat OpenShift Container Platform. For more information about container security, see the Red Hat® documentation: Security and compliance.

As an additional layer of security, all communications between Red Hat OpenShift Container Platform nodes can be transparently encrypted (in additional to the TLS encryption at the application layer). To ensure that encryption in motion is enabled between each service or node within your Red Hat OpenShift Container Platform cluster, you must enable IPsec on Red Hat OpenShift Container Platform. When you install Red Hat OpenShift Container Platform, specify an empty object for the **ipsecConfig** parameter to enable IPsec encryption, as in the following example:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    type: OVNKubernetes
    ovnKubernetesConfig:
      ipsecConfig: {}
```

Note: IPsec enablement status cannot be changed after cluster installation.

For more information, see IPsec encryption configuration and Specifying advanced network configuration in the Red Hat OpenShift Container Platform documentation.

Platform considerations for GDPR readiness

Notice

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of IBM Cloud Pak® for AIOps that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations.

The products, services, and other capabilities described are not suitable for all client situations and may have restricted availability. IBM® does not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.

Table of Contents

- GDPR
- Product Configuration for GDPR
- Data Life Cycle
- Data Collection
- Data Storage
- Data Access
- Data Processing
- Data Deletion
- Data Monitoring
- Capability for Restricting Use of Personal Data

GDPR

General Data Protection Regulation (GDPR) has been adopted by the European Union ("EU") and applies from May 25, 2018.

Why is GDPR important?

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for non-compliance
- Compulsory data breach notification

Read more about GDPR

Product Configuration - considerations for GDPR Readiness

The following sections describe aspects of data management within IBM Cloud Pak for AIOps and provide information on capabilities to help customers with GDPR requirements.

Data Life Cycle

IBM Cloud Pak for AIOps is an AIOps platform that deploys advanced, explainable AI across the ITOps toolchain so you can confidently assess, diagnose, and resolve incidents across mission-critical workloads.

IBM Cloud Pak for AIOps deals primarily with technical data, some of which might be subject to GDPR. IBM Cloud Pak for AIOps also deals with information about users who manage the deployment. This data is described throughout this document for the awareness of customers responsible for meeting GDPR requirements. This data is persisted on local or remote file systems as configuration files or in databases. Applications that integrate with IBM Cloud Pak for AIOps might deal with other forms of personal data subject to GDPR. The mechanisms that are used to protect and manage data are also available to applications that integrate with IBM Cloud Pak for AIOps. Extra mechanisms might be required to manage and protect personal data that is collected by these applications.

To best understand IBM Cloud Pak for AIOps and its data flows, you must understand how Kubernetes and Docker work. These open source components are fundamental to IBM Cloud Pak for AIOps.

IBM Cloud Pak for AIOps includes a catalog of containerized software and services from IBM® in the default IBM Cloud Pak for AIOps repository list. To view a list of all the IBM Cloud Pak for AIOps charts, see IBM/charts. For considerations about GDPR for the products in the catalog, consult the documentation for those products. Some of the applications available in the catalog are open source software. It is the customer's responsibility to determine and implement any appropriate GDPR controls for open source software. Information on these packages is included in the catalog entry.

What types of data flow through IBM Cloud Pak for AIOps platform

IBM Cloud Pak for AIOps deals with several categories of technical data that might be considered as personal data. Categories include administrator user IDs and passwords, service user IDs and passwords, IP addresses, and Kubernetes node names. IBM Cloud Pak for AIOps also deals with information about users who manage the deployment. Integrated applications might introduce other categories of personal data unknown to IBM Cloud Pak for AIOps.

Information on how this technical data is collected or created, stored, accessed, secured, logged, and deleted is described in later sections of this document.

Personal data used for online contact with IBM

Customers can submit online comments/feedback/requests to contact IBM about IBM Cloud Pak for AIOps subjects in various ways, primarily:

- The public IBM Cloud Pak for AIOps Slack Community
- Public comments area on pages of IBM Cloud Pak for AIOps product documentation in the IBM Documentation

Typically, only the customer name and email address are used to enable personal replies for the subject of the contact. The use of personal data conforms to the IBM Online Privacy Statement.

Data Collection

IBM Cloud Pak for AIOps does not collect any special categories of personal data. It does create and manage technical data, such as an administrator user ID and password, service user IDs and passwords, IP addresses, and Kubernetes node names, which might be considered personal data. IBM Cloud Pak for AIOps also deals with information about users who manage the offering. All such information is only accessible by the administrator.

Applications that run on IBM Cloud Pak for AIOps might collect personal data.

To assess the use of IBM Cloud Pak for AIOps running containerized applications and your need to meet the requirements of GDPR, you must consider the types of personal data that the application collects and aspects of how that data is managed, such as:

- How is the data protected as it flows to and from the application? Is the data encrypted in transit?
- How is the data stored by the application? Is the data encrypted at rest?
- How are credentials, which are used to access the application, collected and stored?
- How are credentials, which are used by the application to access data sources, collected and stored?
- How is data collected by the application removed as needed?

This list is not a definitive list of the types of data collected by IBM Cloud Pak for AIOps. It is provided as an example for consideration. If you have any questions about the types of data, contact IBM.

Types of personal data

- Basic Personal Information (such as name, address, phone number, email)

- Technically Identifiable Personal Information (such as device IDs, usage-based identifiers, static IP addresses - when linked to an individual).

Special categories of personal data

- IBM Cloud Pak for AIOps was not designed to process any special categories of personal data.

Data storage

IBM Cloud Pak for AIOps persists technical data in stateful stores on local or remote file systems as configuration files or in databases. Consideration must be given to securing all data at rest. IBM Cloud Pak for AIOps supports encryption of data at rest in stateful stores. For more information, see Security considerations

Data access

IBM Cloud Pak for AIOps provides a number of groups and roles for controlling data access. The groups and roles enable differentiation between normal users and those with extra privileges. For more information, see Roles and permissions.

Data Processing

In general, data that is used for authentication must be in a directory service or LDAP. Databases are provisioned during installation. Make sure to maintain them throughout product lifecycles.

Basic recommendations

- Regularly back up data, according to your business needs and to the risk level.
- Encrypt data backups.
- When data is no longer used, delete the databases or archive them for future use.
- As a data controller, provide means to satisfy data access requests for personal information or other compliance requests.

Further considerations

- Make sure that control of access to databases is in place and effective.
- Use strong credentials.
- Protect the REST administration APIs with proper credentials.
- Use HTTPS or equivalent secure communication protocols for all integrations.
- Remove or change all default passwords.

Data Deletion

Article 17 of the GDPR states that data subjects have the right to request that their personal data is removed from the systems of controllers and processors, without undue delay. Implement appropriate controls and tools to satisfy this right.

IBM Cloud Pak for AIOps does not require any special method for data deletion.

Data that reflects personally identifiable information (PII) can be in all stages of the data processing pipeline. Data deletion must include all these stages. Administrators can use IBM Cloud Pak for AIOps features to remove user data.

Data monitoring

Regularly test, assess, and evaluate the effectiveness of your technical and organizational measures to comply with GDPR. These measures should include ongoing privacy assessments, threat modeling, centralized security logging, and monitoring, among others.

Capability for Restricting Use of Personal Data

Using the facilities summarized in this document, IBM Cloud Pak for AIOps enables a user to restrict usage of any technical data that is considered personal data.

Under GDPR, users have rights to access, modify, and restrict processing. Refer to other sections of this document to manage the following controls:

- Right to access
  - Administrators can use IBM Cloud Pak for AIOps features to provide individuals access to their data.
  - Administrators can use IBM Cloud Pak for AIOps features to provide individuals information about what data IBM Cloud Pak for AIOps platform holds about the individual.
- Right to modify
  - Administrators can use IBM Cloud Pak for AIOps features to allow an individual to modify or correct their data.
  - Administrators can use IBM Cloud Pak for AIOps features to correct an individual's data for them.
- Right to restrict processing
  - Administrators can use IBM Cloud Pak for AIOps features to stop processing an individual's data.

When configuring logs from their environments to be stored or processed in IBM Cloud Pak for AIOps, users are responsible for filtering out personal information or other sensitive information. For more information about filtering logs, see the following topics:

- Creating ELK integrations
- Creating Falcon LogScale integrations
- Creating Mezmo integrations

- Creating Splunk integrations

Data retention

IBM Cloud Pak for AIOps does retain data for processing, analysis, and historical purposes. Review the following default retention periods to learn the duration that data is retained.

Default data retention periods

Default retention periods for data

Data type	Default retention period
Logs	- Retention period: 3 days - Normalized logs are retained for 3 days.
Metrics	- Retention period: 15 days - Metric time series data is retained for 15 days.
Events	- Retention period: N/A - Events are not retained after processing.
Alerts	- Retention period: 90 days - Open alerts are kept indefinitely. - Closed alerts are archived and retained for 90 days.
Incidents	- Retention period: N/A - Open incidents are kept indefinitely. - Closed incidents are purged when closed.
Tickets	- Retention period: Indefinite - Closed tickets from a historical time frame are retrieved from the ticketing system based on a user defined date range. Each subsequent retrieval adds to the total data set. Retention controls are not provided.
Topology	- Retention period: 30 days - Valid resources are kept indefinitely. - Deleted or changed resources are deleted after 30 days. - Event correlation and associated analytics use the current topology.

Configuring the retention period for topology resources

You can configure the retention period for topology resources if required. For instance, you can increase the retention period to a maximum of 90 days.

The retention period for historical resource data is configured through the **`HISTORY_TTL`** time to live (TTL) configuration property. You can increase the retention period by increasing this property value. When a resource is deleted, the resource no longer appears in the UI. Historic representations of the resource, however, are retained and can be accessed in the UI history timeline until the history TTL limit is reached, after which the data is deleted.

Caution: Performance and scalability are affected by the number of resources that are managed, the amount of history present for each resource, and the ingestion rate. If you increase the retention period for historical resource data from the default of 30 days (up to a maximum of 90 days), your system performance (when rendering views) might deteriorate, if as a result of this increase resources have in excess of 25,000 historical entries.

To configure the **`HISTORY_TTL`** time to live (TTL) property, complete the following steps on your cluster:

1. Log in to your cluster.
2. Open the **`$ASM_HOME/.env`** file for editing in your preferred editor.
3. Edit the **`HISTORY_TTL`** setting to set your preferred retention period (in hours). You can change the default setting of **`720`** hours (30 days) to a maximum of **`2160`** hours (90 days).
4. Restart the topology service:

   ```
   $ASM_HOME/bin/asm_start.sh
   ```

Configuring the retention period for log resources

You can configure the retention period for log resources if required.

1. Log in to your OpenShift Container Platform cluster.
2. Go to **Deployments**.
3. In Deployments, search for **golden-signal** under the Name field.
4. Click **aimanager-aio-log-anomaly-golden-signals** resource.
5. Click **Environment**.
6. Edit the value for **LAGS_RETENTION_DAYS**. The default value is set to 3 days.

Getting started

Now that you want to get started with IBM Cloud Pak® for AIOps, it's time to learn about all of the capabilities afforded to you by IBM Cloud Pak, and how to take advantage of these capabilities.

Before installing IBM Cloud Pak for AIOps, take the time to understand your needs. IBM Cloud Pak for AIOps includes many features by default. If you have a clear understanding of what you're looking to do with IBM Cloud Pak for AIOps, your installation might be more straightforward.

Choosing the deployment platform

IBM Cloud Pak for AIOps can be installed on Red Hat® OpenShift® Container Platform or on Linux®.

Red Hat OpenShift is supported on most major cloud providers, and is a robust platform for large-scale Kubernetes deployments like IBM Cloud Pak for AIOps. It also provides a console interface for administering and managing your deployment. Linux is offered as an alternative platform to provide an easier getting started experience for users who are not familiar with Red Hat OpenShift.

Deployments on both platforms offer similar capabilities and scaling, but you must consider the following key differences when you are deciding which platform to install IBM Cloud Pak for AIOps on:

- **Hardware requirements**: IBM Cloud Pak for AIOps has the same hardware requirements on both platforms, but deployments on Linux use local storage and benefit from reduced resource requirements by not requiring a storage cluster or cloud storage.
- **Ease of installation**: The deployment of IBM Cloud Pak for AIOps on Red Hat OpenShift requires you to provision a cluster that is running Red Hat CoreOS, deploy Red Hat OpenShift, deploy and configure storage, and install IBM Cloud Pak for AIOps. You must have knowledge of the installation, configuration and administration of Red Hat OpenShift, and of the storage provider that you select. A deployment on Linux is simpler - it requires you to provision a cluster of virtual machines (VMs) and then use an IBM Cloud Pak for AIOps command line tool to configure local storage and install IBM Cloud Pak for AIOps.
- **Backup and restore**: The backup and restore process for deployments of IBM Cloud Pak for AIOps on Linux uses offline VM backups which requires outage time. The backup and restore process for deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift is an online backup that uses IBM Storage Fusion (license restrictions apply), and does not require outage time.
- **Multi-zone high availability**: This is a technology preview feature for deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift. This feature is not available for deployments of IBM Cloud Pak for AIOps on Linux (though deployments are still highly available).
- **FIPs mode**: This feature is not supported for deployments of IBM Cloud Pak for AIOps on Linux.
- **Secure Tunnel**: This feature is not supported for deployments of IBM Cloud Pak for AIOps on Linux.
- **Cognos integration**: This feature is not supported for deployments of IBM Cloud Pak for AIOps on Linux.

Workflows

To help first-time users get started, guided tours are included within the UI console. These tours introduce users to the various UI options and components, and demonstrate how to complete key tasks across the platform. Users can access the tours at any time by clicking the Tours icon in the console toolbar, and selecting their preferred tour.

For more information about working with the IBM Cloud Pak, see the following topics:

- Workflows
- Guided tours
- Roles and archetypes

Archetypes and user roles

For IBM Cloud Pak® for AIOps, different persona archetypes are defined to help you understand the different available and supported tasks so that you can get your environment up and running or begin your day to day operations quickly and efficiently.

Archetypes are a set of basic characteristics that a user role can fulfill. You can think of an archetype as a templated job description for a particular user role. For example, in IBM Cloud Pak for AIOps, the Site reliability expert is responsible for many tasks assessing and remediating problems. The Site reliability expert falls under the Infrastructure engineer archetype, that is, someone who is focused on keeping the entire IT infrastructure of an organization up and running 24 x 7.

The following defined archetypes and user roles are referenced within the product documentation as the user for completing different use cases and tasks:

- Application developer
- Infrastructure engineer

Archetype: Application developer

Application developers in IBM Cloud Pak for AIOps are responsible for building things outside of the scope of enterprise IT security. Application developers want to solve problems early so that they can focus on new feature development and not dwell on debugging IT issues. Application developers work hand in hand with the Security operations manager and Infrastructure engineer to identify and fix issues. The following user roles are often associated with the Application developer archetype:

- Software engineer
- Software developer
- DevOps engineer
- Full stack developer

The following table lists the high-level key tasks that Application developers can complete with IBM Cloud Pak for AIOps:

Table 1. Archetype: Application developer tasks and references

Tasks	References
Monitor outgoing integrations for issues	ChatOps insight management
Debug issues that are associated with applications and related services	Managing incidents

Archetype: Infrastructure engineer

Infrastructure engineers play a vital role in IBM Cloud Pak for AIOps as they ensure that systems are always up and running. They serve as the go-between from the strategy and high level thinking of the Security operations manager to the implementation by the Application developers. Infrastructure engineers are always aware of their platforms, ensuring that problems are detected and remediated as quickly as possible. If all goes well, the Infrastructure engineer is responsible for a platform that never goes down. The following user roles are often associated with the Infrastructure engineer archetype:

- Site reliability engineer
- Systems engineer
- Operations engineer
- Platform engineer

The following table lists the high-level key tasks that Infrastructure engineers can complete with IBM Cloud Pak for AIOps:

Table 2. Archetypes: Infrastructure engineer tasks and references

Tasks	References
Install IBM Cloud Pak for AIOps	Deploying IBM Cloud Pak for AIOps on OpenShift or Deploying IBM Cloud Pak for AIOps on Linux
Administer IBM Cloud Pak for AIOps	Cloud Pak administration
Setting up integrations	Configuring Integrations
Training AI models	Configuring AI training
Managing topologies	Application management
Monitor outgoing integrations for issues	ChatOps insight management
Debug issues that are associated with applications and related services	Managing incidents

IBM Cloud Pak for AIOps workflows

You decided to install IBM Cloud Pak® for AIOps, now it's time to explore the key workflows of your users and their interaction with IBM Cloud Pak for AIOps.

Understanding how you can accomplish your tasks, who's responsible, and how each workflow fits together gives you a holistic picture of your entire AIOps-infused IT infrastructure management experience. You can bring IBM Cloud Pak for AIOps to life by deploying more operators, customizing your configurations, and optimizing IBM Cloud Pak for AIOps performance. For more information about how to get the most out of your team, see Archetypes.

Installing IBM Cloud Pak for AIOps

Deployments on Red Hat® OpenShift® Container Platform

Platform engineers prepare all required hardware and software, and then install the Red Hat® OpenShift® Container Platform. They prepare OpenShift clusters and install IBM Cloud Pak for AIOps into those clusters.

For more information about installing IBM Cloud Pak for AIOps, see the following sections:

- Planning installation, configuration, and overall cluster requirements
- Preparing for and installing IBM Cloud Pak for AIOps

Deployments on Linux®

Platform engineers prepare all required hardware and software. They prepare the Linux cluster and install IBM Cloud Pak for AIOps onto the cluster.

For more information about installing IBM Cloud Pak for AIOps, see the following sections:

- Planning installation, configuration, and overall cluster requirements
- Preparing for and installing IBM Cloud Pak for AIOps

Guided tours

To help first-time users get started with some workflows, guided tours are included within the UI console across the different dashboards. These tours introduce users to the various UI options and components, and demonstrate how to complete key tasks across the platform. Users can access the tours at any time by clicking the Tours icon in the console toolbar, and selecting their preferred tour.

For more information about the available guided tours, see Guided tours.

Setting up integrations

You can create integrations for logs, to establish a baseline of normal behavior and identify anomalies. Other integrations provide event, applications, and infrastructure data to IBM Cloud Pak for AIOps.

Systems engineers create integrations to ticketing and to ChatOps tools. The integrations to ticketing tools have a dual purpose: they enable ticket data to be collected for change request and similar ticket training. The same integration also enables synchronization between IBM Cloud Pak for AIOps incidents and corresponding ServiceNow tickets. The integrations to Microsoft Teams and Slack ChatOps tools enable incident notifications to be pushed to these ChatOps tools. These notifications are for the attention of Site Reliability Engineers who are tasked with resolving those incidents.

IBM Cloud Pak for AIOps provides many connectors, probes, and observers by default for setting up integrations with common IBM and third-party systems and services. In addition, if a default integration is not available for connecting to a system or service that you want to use with IBM Cloud Pak for AIOps, you can set up a custom integration to connect to that system or service.

For more information about setting up integrations, see the following sections:

- Defining outgoing integrations
- Defining incoming integrations

Loading data and training AI

As a prerequisite to training your AI to provide insights on your monitored environment, systems engineers load event, log, metric, ticket, and other data from various data sources. They then run different types of AI training to generate AI models such as log anomaly models, which can easily identify and report on anomalies in your log data. Insights that are generated by these AI models are used to enrich incidents with related alert, similar ticket, and event grouping information.

For more information about loading data and training AI, see the following sections:

- Planning data loading and training
- Defining incoming integrations
- Configuring AI training

Building applications

Systems engineers are responsible for building the applications that are monitored by Site Reliability Engineers. Systems engineers build applications from the ground up, by first defining observer integrations to import resource topology data, and then defining templates to automatically generate resource groups from the incoming observer streams. When they have an incoming dynamic stream of resource groups, they build business applications that are made up of multiple resource groups.

For more information about building applications, see the following sections:

- Defining observer jobs
- Defining templates with template builder
- Creating and editing applications
- Viewing applications

Creating automations

System administrators set up policies, runbooks, and actions to detect and remediate incoming alerts. Policies are rules that contain a condition and a set of outcomes that can be manual or automated. Runbooks help to solve common operational problems by automating procedures that do not require human interaction. Procedure-based documentation can be transferred into manual runbooks. Actions in runbooks are the collection of several manual steps into a single automated entity. Actions can be added to create semi-automated or fully automated runbooks.

For more information about creating automations, see the following sections:

- Creating policies
- Creating a runbook
- Creating an action

Resolving incidents

Site reliability engineers are responsible for investigating and resolving incidents and incidents that are associated with applications and infrastructure. They use ChatOps tools such as Microsoft Teams and Slack to monitor incident channels, and investigate incidents by using application, topology, ticketing, alert, and similar ticket information provided in the incident notification. They act to resolve the incidents, where necessary involving Applications developers.

For more information about resolving incidents, see the following sections:

- ChatOps insight management
- Application incidents

Administering the cluster

Platform engineers administer the cluster on which IBM Cloud Pak for AIOps is installed on an ongoing basis. They ensure that all nodes, pods, and other elements within the cluster are performing as expected. They also support the systems engineer with complex cluster administration tasks such as multitenancy management, project (namespace) management, and authorization and authentication of users within the cluster.

Administering IBM Cloud Pak for AIOps

Systems engineers, or in some organizations, Operations engineers, are responsible for authenticating and managing users. They can also customize the UI experience by setting console branding and customizing what content users see on the home page. For more complex cluster-based tasks such as multitenancy management, project (namespace) management, and authorization and authentication of users within the cluster, they collaborate with the Platform engineer.

For more information about administering IBM Cloud Pak for AIOps, see the following sections:

- Managing user access control
- Customizing the platform UI

Deploying IBM Cloud Pak for AIOps on Linux

You can install a production deployment of IBM Cloud Pak® for AIOps directly on a Linux® cluster, without the need to install Red Hat® OpenShift® Container Platform. Online and offline deployments are supported.

If you need help deciding whether to install IBM Cloud Pak for AIOps on Red Hat OpenShift or Linux, see Choosing the deployment platform.

Read about planning an installation of IBM Cloud Pak for AIOps on Linux, and then select one of the installation options:

- Planning - learn about the system requirements for installing IBM Cloud Pak for AIOps on a Linux cluster.
- Online installation - follow these instructions if your cluster is connected to the internet.
- Offline installation - follow these instructions if your cluster is not connected to the internet.

Learn about upgrading, administering, and uninstalling IBM Cloud Pak for AIOps on Linux:

- Online upgrade
- Offline upgrade
- Administering
- Uninstalling

Planning an installation of IBM Cloud Pak for AIOps on Linux

Learn about the system requirements for an installation of IBM Cloud Pak for AIOps on Linux.

Before you begin

- There is not a small starter size option for the installation of IBM Cloud Pak® for AIOps on Linux®. You can only deploy a production size deployment.
- vCPU is defined as when one x86 CPU splits each of its physical cores into virtual cores (vCPU). It is assumed that one x86 CPU's physical core can be split into two logical vCPUs.
- If Linux is installed on VMware virtual machines, set the value of the `sched.cpu.latencySensitivity` parameter to high.
- You can deploy a base deployment of IBM Cloud Pak for AIOps that does not have log anomaly or ticket analysis capabilities, or an extended deployment of IBM Cloud Pak for AIOps with these capabilities. Learn more

Review the information in the following sections:

- Supported platforms
- Hardware requirements
- Processing abilities
- Custom sizing
- Storage requirements
- Configuring local volumes
- Network requirements
- High availability considerations
- Load balancing
- DNS requirements
- Security considerations
- Licensing

Supported platforms

IBM Cloud Pak for AIOps can be installed on the following platform versions:

- Red Hat® Enterprise Linux® 8.10 only
- Red Hat® Enterprise Linux® 9.4 only
- Ubuntu 24.04 LTS

The hardware architecture for installing IBM Cloud Pak for AIOps must be x86_64 (amd64).

If you want to install IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform or on a cloud platform, see Deploying IBM Cloud Pak for AIOps on OpenShift.

Hardware requirements

Multiple Linux nodes are needed, and IBM Cloud Pak for AIOps is installed on this cluster of nodes. The cluster must be reserved for the sole use of IBM Cloud Pak for AIOps.

Three of these nodes must be control plane nodes. The control plane nodes coordinate the running of IBM Cloud Pak for AIOps across the other nodes, and are the entry point into the product. Worker or agent nodes provide more compute resources to run IBM Cloud Pak for AIOps services. All the nodes can be assigned as agent nodes, but three of the nodes must also be assigned as control plane nodes.

The size of each of your nodes can vary, but each worker node must meet the minimum requirements in Table 1 to accommodate the placement of larger IBM Cloud Pak for AIOps pods, and the combined resources of your nodes must comply with the resource totals in Table 2.

You must ensure that the clocks on your Linux cluster are synchronized. Each node in the cluster must have access to an NTP server to synchronize their clocks. Discrepancies between the clocks on the nodes can cause IBM Cloud Pak for AIOps to experience operational issues.

Warning: Insufficient hardware will result in product instability and loss of function. Verify that your hardware is sufficiently sized for your expected workloads. For more information, see Processing abilities. In addition to the default production size deployment, you can choose to deploy a custom-sized deployment of IBM Cloud Pak for AIOps. For more information, see Custom sizing.

Minimum node requirements

Each of the worker and control plane nodes in your cluster must meet the minimum size requirements in the following table:

Table 1. Minimum node requirements

Resource	Requirement
vCPU per node	16
Memory per node (GB)	20
Disk per node (GB)	120

Overall cluster requirements

Your cluster must meet the overall size requirements in the following table.

Table 2. Overall cluster requirements

Resource	Base deployment requirement	Extended deployment requirement
Node count	9	9
Total vCPU	148	174
Total memory (GB)	358	416

Table 2 shows the hardware requirements for a deployment of IBM Cloud Pak for AIOps on a Linux cluster, for a base deployment and an extended deployment. For more information about the differences between a base deployment and an extended deployment, see Incremental adoption.

Important:

- Three of these nodes must be control plane nodes.
- An extra 1 vCPU and 3 GB memory is required for each integration that you configure. For example, if you configure two Netcool integrations then you will require an additional 2 vCPUs and 6 GB memory.
- You will also require an additional server for a load balancer. For more information, see Load balancing.

Integrations

When you are configuring an integration in IBM Cloud Pak for AIOps, it is important to consider the performance and footprint. If you have large amounts of data on the selected target system, you can expect relatively higher resource usage from collecting data from that system when compared to a system with less data. Additionally, the sizing of the IBM Cloud Pak for AIOps installation affects the number of resources that are available for running integrations. Review the following considerations for each integration category and the **integration installation** section before you configure a new integration.

Integration installation

IBM Cloud Pak for AIOps integrations for metrics, events, and logs are configured in the Integrations UI page, which can be used to create, edit, delete, and track the status of integrations. Integrations run as pods and have minimum and maximum resource allocations in terms of CPU, memory and storage. Some integrations offer flexibility in terms of how to install the integration in the UI, but some integrations only offer one option.

You can use the following two options to install integrations:

- **Local**: Install the integration in the same cluster and namespace where IBM Cloud Pak for AIOps is installed. The integration's status is displayed in the Integrations UI page and is automatically managed by IBM Cloud Pak for AIOps.
- **Remote**: Install the integration anywhere you choose, for example, a different network region, on SaaS, or remote on-premises (VM, cluster or container). After adding the integration, you can use the script to run the integration pod using podman.

Regardless of whether an integration is a local or remote installation, the data collected by IBM Cloud Pak for AIOps is stored for some time in Kafka.

Hardware requirements - Integrations

Before you create an integration for both local and remote installation, make sure that IBM Cloud Pak for AIOps or remote environment contains the hardware resources that are required to run the integrations.

The minimum resource requirements for the integrations are listed in the following table:

Table 3. Minimum requirements for integrations

Integration name	Memory limit (Mb)	CPU limit	Ephemeral storage limit (Mb)
AppDynamics New Relic Splunk	2500	1	500

Integration name	Memory limit (Mb)	CPU limit	Ephemeral storage limit (Mb)
AWS CloudWatch, Dynatrace (metrics-only), Infrastructure Management, Generic Webhook, Zabbix	4096	1	500
Dynatrace (metrics, events, topology)	10000	4	8000
DB2, GitHub, ServiceNow	800	1	1000
Email Notifications, IMPACT, Jira	512	1	1000
Instana	4096	4	1000
Netcool ObjectServer	4096	2	2000
Custom, Elk, Falcon LogScale, Mezmo	1536	1	1000

Notes:

- Dynatrace (metrics, events, topology) supports up to 5 integrations.
- The hardware sizing in the preceding table does not include resource slots for logs integrations or observer jobs. For more information about resource slots for logs integrations, see Performance considerations for logs data collection. For more information about defining observer jobs, see Observer jobs.

For performance considerations for integrations, see the following sections:

- Performance considerations for metrics data collection
- Performance considerations for logs data collection
- Performance considerations for events data collection
- Performance considerations for tickets data collection
- Performance considerations for observers

Processing abilities

Expand the following sections to find out about the processing abilities of a production deployment of IBM Cloud Pak for AIOps. Higher rates are supported by custom sizes. For more information about customizing the size of your IBM Cloud Pak for AIOps deployment according to your processing and footprint requirements, see Custom sizing.

▶ Supported resource number and throughput rates for production deployments

▶ Event, alert, and incident rates

Custom sizing

The default production deployment size enables the full capabilities of IBM Cloud Pak for AIOps to be used with the workload volumes that are stated in the Processing abilities section. If different workload volumes are required or resource constraints are an issue, then specific capabilities such as **`Metric Anomaly Detection`**, **`Log Anomaly Detection`**, and **`Runbook Automation`** can be sized accordingly. IBM Sales representatives and Business Partners have access to a custom sizing tool that can assess your runtime requirements and provide a custom profile that scales IBM Cloud Pak for AIOps components. The custom profile is applied when you install IBM Cloud Pak for AIOps. This custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. If you require custom sizing, contact IBM Sales representatives and Business Partners with details of your intended workloads.

The following table shows the processing abilities of some custom-sized deployments of IBM Cloud Pak for AIOps.

Example 1 (Minimum scale) represents a minimally sized deployment of IBM Cloud Pak for AIOps for the evaluation of event management. It demonstrates event analytics, noise reduction, and the automation of issue resolution on a small topology. Metric and log anomaly detection and change risk assessment are de-emphasized. Example 1 requires 49.36 vCPU and 155GB of memory to run on a 9 node Linux cluster, this includes an overhead of 12GB of memory and 0.36 of a vCPU. If there are more than 9 nodes in the cluster, then extra resources are required as follows: 0.06 of a core and 3GB for each control plane node, and 0.03 of a core and 0.5GB for each worker node.

Example 2 (Event management focused) represents a production deployment of IBM Cloud Pak for AIOps which is focused on event management capabilities. It supports event analytics, noise reduction, and the automation of issue resolution on a large topology. Metric and log anomaly detection and change risk assessment are de-emphasized. Example 2 requires 176.36 vCPU and 378 GB memory to run on a 9 node Linux cluster, this includes an overhead of 12GB of memory and 0.36 of a vCPU. If there are more than 9 nodes in the cluster, then extra resources are required as follows: 0.06 of a core and 3GB for each control plane node, and 0.03 of a core and 0.5GB for each worker node.

Maximum scale shows the upper limits that IBM Cloud Pak for AIOps can be scaled to, across all of its capabilities.

Table 5. Processing abilities of example custom-sized deployments

Component	Resource	Example 1	Example 2	Maximum scale
Change risk	Incidents and change request records per second	0	0	N/A
Metric anomaly detection	Maximum throughput - (KPIs) for all metric integration	0	0	5,000,000
Log anomaly detection	Maximum throughput (log messages per second) for all log integrations	0	0	25,000
Events (through Netcool integration)	Steady state event rate throughput per second Burst rate event throughput per second	10	600	700 1000
Automation runbooks	Fully automated runbooks run per second	1	2	4
Topology management	Maximum number of topology resources	5,000	5,000,000	15,000,000
UI users	Active users supported	5	40	40

Storage requirements

IBM Cloud Pak for AIOps deployments on Linux require 3000 GB of persistent local storage across all of the nodes in your Linux cluster. Each node must have a minimum of 250GB. To meet the local storage requirements, you must configure distributed storage across the nodes in your Linux cluster, and dedicate specific disks and logical volumes for application and platform storage. Follow the instructions in Configuring local volumes.

Important: The file system used by MinIO must be **`XFS`**, not **`ext4`**. The **`ext4`** file system has a limit on the number of inodes that can be created for each file system. If inode usage reaches 100%, the file system becomes read-only even if enough PVC space is available and MinIO is prevented from creating new files or directories. Refer to your storage provider's documentation for information about setting **`XFS`** as the file system.

Additional requirements for offline deployments

If you are installing in an air-gapped environment (offline), you must also ensure that you have adequate space to download the IBM Cloud Pak for AIOps images to the target registry in your offline environment. The IBM Cloud Pak for AIOps images total 143 GB.

IOPS requirements

The following table identifies the input/output operations per second (IOPS) per node that must be supported. Ensure that your hardware can support the expected IOPS per node. A minimum configuration of three nodes for the storage cluster is needed. Each node of the storage solution requires a minimum of one disk (SSD or high-performance storage array). The results for your storage can vary depending on your exact usage, data sets, hardware, storage solution, and more.

Table 6. IOPS requirements

Deployment size	Minimum	Recommended
Production deployment	10,000	20,000

Network requirements

The control plane nodes require the following access:

Table 7. Control plane node access

Port number	Direction	Protocol	Description
80	Inbound from load balancer	TCP	Application HTTP port
443	Inbound from load balancer	TCP	Application HTTPS port
6443	Inbound from cluster worker nodes Between control plane nodes	HTTPS	Control plane server API
5001	Between cluster nodes	TCP	Distributed registry
8472	Betwen cluster nodes	UDP	Virtual network

Worker nodes require the following access:

Table 8. Worker node access

Port number	Direction	Protocol	Description
6443	Outgoing to control plane nodes		IBM Cloud Pak for AIOps components
5001	Between cluster nodes	TCP	Distributed registry
8472	Between cluster nodes	UDP	Virtual network

Firewall rules

Some Linux distributions require extra firewall rules to avoid potential conflicts or restrictions.

1. Check whether the firewall is enabled.

   ```
   systemctl status firewalld
   ```

   If the firewall is enabled, then the command output provides the status of the firewall, including any active rules. If the firewall is disabled, then the command outputs the message *No such file or directory.*

2. If the firewall is enabled, run the following commands:

   ```
   firewall-cmd --permanent --add-port=6443/tcp #apiserver
   firewall-cmd --permanent --zone=trusted --add-source=10.42.0.0/16 #pods
   firewall-cmd --permanent --zone=trusted --add-source=10.43.0.0/16 #services
   firewall-cmd --reload
   ```

3. If you are permitting the collection of usage data, then ensure that outbound traffic to https://api.segment.io is allowed. For more information, see Updating usage data collection preferences.

nm-cloud-setup service

The **`nm-cloud-setup`** service must not be enabled. Run the following steps on each of your nodes.

1. Check if **`nm-cloud-setup.service`** is enabled.

   ```
   systemctl is-enabled nm-cloud-setup.service
   ```

   If the service is enabled, the command returns **`enabled`**.

2. If the service is enabled, then disable it and reboot the node.

```
systemctl disable nm-cloud-setup.service nm-cloud-setup.timer
reboot
```

High availability considerations

IBM Cloud Pak for AIOps uses a minimum of three control plane nodes and multiple worker nodes to improve resiliency if a node failure occurs.

A procedure is also provided to delete a failed and inaccessible node, for more information, see Recovering from node failure.

Load balancing

IBM Cloud Pak for AIOps requires a load balancer to distribute incoming traffic among the three control plane nodes. The load balancer is a mandatory component, and if you do not already have a load balancer then you must configure one of your choice.

The load balancer requires the following access:

Table 9. Load balancer access

Port number	Description
443	Inbound IBM Cloud Pak for AIOps requests
6443	Inter-cluster communications: inbound from worker nodes, outbound to control plane nodes
(optional) 80	For inbound IBM Cloud Pak for AIOps requests, redirects to secure port 443. If you disable this port, users must type `https://` as part of the URL when they first navigate to the IBM Cloud Pak for AIOps console.

The load balancer is the entry point for accessing IBM Cloud Pak for AIOps. It is important to try to ensure the load balancer's high availability, as any downtime or outage will render IBM Cloud Pak for AIOps inaccessible. Consider adding the load balancer to the startup configuration (such as `init.d`) on the server where it is installed. This configuration will enable the load balancer to launch automatically during the boot process, minimizing downtime if an outage occurs.

For more information about load balancers, see the IBM topic What is load balancing?

Expand the following section to view an example configuration for a HAProxy load balancer. This example is provided as a reference only, consider your own internal policies and practices when you create the configuration for your chosen load balancer.

▶ Example load balancer configuration

DNS requirements

IBM Cloud Pak for AIOps requires a Domain Name System (DNS) server in the environment, with resolution for the following two hosts:

- `<load_balancer_ip> aiops-cpd.<your fully-qualified server domain name>`
- `<load_balancer_ip> cp-console-aiops.<your fully-qualified server domain name>`

Where `<load_balancer_ip>` is the IP address of your load balancer.

Important: The DNS server must provide name resolution for all of the nodes in the cluster.

Security considerations

Ensure that you keep up to date on any security-related news or vulnerabilities with IBM Cloud Pak for AIOps by subscribing to security bulletins.

The `aiopsctl` tool must run with root privileges.

For more information about the permissions that are required for Cloud Pak for AIOps, see Permissions.

You can use a custom certificate for IBM Cloud Pak for AIOps instead of the default cluster certificate. For more information, see Using a custom certificate.

Licensing

License usage tracking is required. The `aiopsctl` tool deploys the IBM Cloud Pak foundational services License Service on your Linux cluster. This background service collects and stores the license usage information for tracking license consumption and for audit purposes. For more information, see Licensing.

Incremental adoption (IBM Cloud Pak for AIOps on Linux)

Learn about incremental adoption and the deployment types that are available for IBM Cloud Pak® for AIOps.

Overview

Incremental adoption offers the flexibility of two deployment types that provide a different combination of footprint and capabilities.

- **Base deployment**: has a smaller footprint than the extended deployment, with vCPU and memory savings of around 15% for a production deployment. The log anomaly detection and ticket analysis (similar incidents and change risk) capabilities are not enabled.
- **Extended deployment**: has a larger footprint and has the full capabilities of IBM Cloud Pak for AIOps enabled.

The IBM Cloud Pak for AIOps license entitles you to use either of the deployment types.

Capabilities and hardware requirements

Log anomaly detection collects and analyzes log data to identify deviations from expected patterns of behavior. For more information, see Log anomaly detection.

Ticket analysis collects ticket data and compares it with similar tickets previously associated with incidents to identify possible remediating changes, and the risk of implementing those changes. For more information, see Similar ticket comparison and Change risk.

For more information about the footprint of each deployment type, see Hardware requirements.

Selecting your deployment type (install and upgrade)

You can choose to install a base deployment or an extended deployment of IBM Cloud Pak for AIOps. The deployment type is configured by an environment variable at installation time, and defaults to a base deployment. For more information about setting the deployment type at installation time, see the topic for your installation method:

- Online installation
- Offline installation

Deployments that upgrade to IBM Cloud Pak for AIOps 4.8.0 have their deployment type set during upgrade. For more information about setting the deployment type during upgrade, see the topic for your installation method:

- Online upgrade
- Offline upgrade

Changing your deployment type (postinstall)

Subject to further hardware requirements, you can update the deployment type of a new or upgraded deployment at any time after installation from a base deployment to an extended deployment. For more information, see Updating the deployment type.

Configuring local volumes for an installation of IBM Cloud Pak for AIOps on Linux

Learn about configuring logical storage volumes for an installation of IBM Cloud Pak for AIOps on Linux.

Overview

Each control plane node in your Linux® cluster must have two separate disks in addition to the boot disk. One disk is dedicated to persistent storage for IBM Cloud Pak® for AIOps, while the other is reserved for platform storage. Similarly, each worker node in the cluster must have a dedicated disk for IBM Cloud Pak for AIOps's persistent storage. This protects and isolates application and platform data from the rest of the node, and provides capacity limiting that protects the root volume from being filled by application data.

IBM Cloud Pak for AIOps deployments on Linux require 3000 GB of persistent local storage across all of the nodes in your Linux cluster. Each node must have a minimum of 250GB.

The following procedure is suggested to create separate logical volumes for IBM Cloud Pak for AIOps's application storage, and for platform storage. The procedure is for logical volume management, and some steps may be different for your chosen storage management solution.

Warning: Although it is possible to configure a separate partition and volume on an existing disk, this is not recommended. For more information, see Multiple partitions on a disk in the Red Hat® Enterprise Linux® documentation.

Procedure

1. Configure logical volumes on the control plane nodes.

   Run the following steps on each of your control plane nodes.

   1. Identify two blank disks that can be used for IBM Cloud Pak for AIOps's application storage and for platform storage.

      ```
      fdisk -l
      ```

      Example output where **/dev/vdb** and **/dev/vdc** can be used:

      ```
      $ fdisk -l

      Device     Boot   Start       End   Sectors  Size Id Type
      /dev/vda1  *       2048   2099199   2097152    1G 83 Linux
      /dev/vda2       2099200 524287999 522188800  249G 8e Linux LVM

      Disk /dev/vdb: 200 GiB, 214748364800 bytes, 419430400 sectors
      Units: sectors of 1 * 512 = 512 bytes
      Sector size (logical/physical): 512 bytes / 512 bytes
      I/O size (minimum/optimal): 512 bytes / 512 bytes

      Disk /dev/vdc: 200 GiB, 214748364800 bytes, 419430400 sectors
      Units: sectors of 1 * 512 = 512 bytes
      Sector size (logical/physical): 512 bytes / 512 bytes
      I/O size (minimum/optimal): 512 bytes / 512 bytes
      ```

2. Export environment variables.

```
export APP_DRIVE_NAMES=(
  <app_drive_name>
)
export PLATFORM_DRIVE_NAMES=(
  <plat_drive_name>
)

export APP_STORAGE_PATH="/var/lib/aiops/storage"
export PLATFORM_STORAGE_PATH="/var/lib/aiops/platform"
```

Where

- **<app_drive_name>** is a blank disk that you identified in step 1. For example: "/dev/vdb"
- **<plat_drive_name>** is a different blank disk that you identified in step 1. For example: "/dev/vdc"

Note: You can set different values for $APP_STORAGE_PATH and $PLATFORM_STORAGE_PATH if you want. If you do, then note the values that you use and ensure that you specify these values when you install IBM Cloud Pak for AIOps. You must use the same value for $APP_STORAGE_PATH for all control plane and worker nodes, and you must use the same value for $PLATFORM_STORAGE_PATH for all control plane nodes.

3. Run the following commands to configure the drives and volumes:

```
# Create physical volumes
pvcreate "${APP_DRIVE_NAMES[@]}"
pvcreate "${PLATFORM_DRIVE_NAMES[@]}"

# Create volume groups
vgcreate aiops "${APP_DRIVE_NAMES[@]}"
vgcreate aiopspl "${PLATFORM_DRIVE_NAMES[@]}"

# Create logical volumes on the volume groups
lvcreate aiops -n aiops -l 100%FREE
lvcreate aiopspl -n aiopspl -l 100%FREE

# Format the new logical volumes
export APP_DMPATH=$(lvs --noheadings -o dmpath aiops | sed -e 's/^[[:space:]]*//')
export PLATFORM_DMPATH=$(lvs --noheading -o dmpath aiopspl | sed -e 's/^[[:space:]]*//')
mkfs.xfs -L aiops "${APP_DMPATH}"
mkfs.xfs -L aiopspl "${PLATFORM_DMPATH}"

# Create filesystem directories
mkdir -p "${APP_STORAGE_PATH}"
mkdir -p "${PLATFORM_STORAGE_PATH}"

# Add the new filesystem directories to `/etc/fstab`
echo "${APP_DMPATH}  ${APP_STORAGE_PATH}     xfs    defaults        0 0" >> /etc/fstab
echo "${PLATFORM_DMPATH}  ${PLATFORM_STORAGE_PATH}     xfs    defaults        0 0" >> /etc/fstab

# Mount the filesystems into the directories
systemctl daemon-reload
mount "${APP_STORAGE_PATH}"
mount "${PLATFORM_STORAGE_PATH}"
```

4. Verify that the mount points are correctly configured.

Run the following command to verify that you have two new mount points called **aiops** and **aiopspl** for the storage locations that you specified, on the disks that you identified.

```
lsblk --output NAME,KNAME,TYPE,MAJ:MIN,FSTYPE,SIZE,RA,MOUNTPOINT,LABEL
```

Example output where **vdb** and **vdc** are now configured as the mount points for **aiops** and **aiopspl**:

```
$ lsblk --output NAME,KNAME,TYPE,MAJ:MIN,FSTYPE,SIZE,RA,MOUNTPOINT,LABEL
NAME               KNAME TYPE MAJ:MIN FSTYPE       SIZE   RA MOUNTPOINT             LABEL
vda                vda   disk 252:0                 250G 4096
├─vda1             vda1  part 252:1   xfs             1G 4096 /boot
└─vda2             vda2  part 252:2   LVM2_member   249G 4096
  ├─rhel-root      dm-0  lvm  253:0   xfs           233G 4096 /
  └─rhel-swap      dm-1  lvm  253:1   swap           16G 4096 [SWAP]
vdb                vdb   disk 252:16  LVM2_member   200G 4096
└─aiops-aiops      dm-2  lvm  253:2   xfs           200G 4096 /var/lib/aiops/storage aiops
vdc                vdc   disk 252:16  LVM2_member   200G 4096
└─aiopspl-aiopspl dm-2  lvm  253:2   xfs           200G 4096 /var/lib/aiops/platform aiopspl
```

2. Configure logical volumes on the worker nodes.

Run the following steps on each of your worker nodes.

1. Identify a blank disk that can be used for IBM Cloud Pak for AIOps's application storage.

```
fdisk -l
```

Example output where **/dev/vdb** can be used:

```
$ fdisk -l

Device     Boot   Start       End   Sectors  Size Id Type
/dev/vda1  *       2048   2099199   2097152    1G 83 Linux
/dev/vda2       2099200 524287999 522188800  249G 8e Linux LVM
```

```
Disk /dev/vdb: 200 GiB, 214748364800 bytes, 419430400 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 512 bytes
```

2. Export environment variables.

```
export APP_DRIVE_NAMES=(
  <app_drive_name>
)

export APP_STORAGE_PATH="/var/lib/aiops/storage"
```

Where **<app_drive_name>** is a blank disk that you identified in step 1. For example: "/dev/vdb"

Note: You can set a different value for $APP_STORAGE_PATH if you want. If you do, then note the value that you use and ensure that you specify this when you install IBM Cloud Pak for AIOps. You must use the same value for $APP_STORAGE_PATH for all control plane and worker nodes.

3. Run the following commands to configure the drives and volumes:

```
# Create physical volumes
pvcreate "${APP_DRIVE_NAMES[@]}"

# Create volume groups
vgcreate aiops "${APP_DRIVE_NAMES[@]}"

# Create a logical volumes
lvcreate aiops -n aiops -l 100%FREE

# Format the new logical volume
export APP_DMPATH=$(lvs --noheadings -o dmpath aiops | sed -e 's/^[[:space:]]*//')
mkfs.xfs -L aiops "${APP_DMPATH}"

# Create filesystem directory
mkdir -p "${APP_STORAGE_PATH}"

# Add the new filesystem directory to `/etc/fstab`
echo "${APP_DMPATH}  ${APP_STORAGE_PATH}     xfs    defaults        0 0" >> /etc/fstab

# Mount the filesystem into the directory
systemctl daemon-reload
mount "${APP_STORAGE_PATH}"
```

4. Verify that the mount point is correctly configured.

Run the following command to verify that you have a new mount point called **aiops** for the storage location that you specified on the disk that you identified.

```
lsblk --output NAME,KNAME,TYPE,MAJ:MIN,FSTYPE,SIZE,RA,MOUNTPOINT,LABEL
```

Example output where **vdb** is now configured as the mount points for **aiops**:

```
$ lsblk --output NAME,KNAME,TYPE,MAJ:MIN,FSTYPE,SIZE,RA,MOUNTPOINT,LABEL
NAME               KNAME TYPE MAJ:MIN FSTYPE       SIZE   RA MOUNTPOINT             LABEL
vda                vda   disk 252:0                 250G 4096
├─vda1             vda1  part 252:1   xfs            1G 4096 /boot
└─vda2             vda2  part 252:2   LVM2_member  249G 4096
  ├─rhel-root      dm-0  lvm  253:0   xfs          233G 4096 /
  └─rhel-swap      dm-1  lvm  253:1   swap          16G 4096 [SWAP]
vdb                vdb   disk 252:16  LVM2_member  200G 4096
└─aiops-aiops      dm-2  lvm  253:2   xfs          200G 4096 /var/lib/aiops/storage aiops
```

Note: If the logical volume sizes need to be increased after installation, follow the instructions in Resizing storage (IBM Cloud Pak for AIOps on Linux).

Online installation of IBM Cloud Pak for AIOps on Linux

Learn about installing IBM Cloud Pak for AIOps on Linux.

Overview

You can install a production deployment of IBM Cloud Pak® for AIOps on a Linux® platform, without installing Red Hat® OpenShift® Container Platform.

The deployment is configured to collect usage data. If you want to disable usage data collection, then you can do this post-install. For more information, see Updating usage data collection preferences.

Limitations

- Starter-size deployments are not supported.

- The following features and capabilities are only available for deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift, and are not available for deployments of IBM Cloud Pak for AIOps on Linux:
  - FIPS support
  - Secure tunnel
  - Multi-zone HADR
  - IBM Cognos® Analytics integration

Before you begin

Ensure that you meet the following prerequisites:

- Your cluster meets all of the requirements that are detailed in Planning an installation of IBM Cloud Pak for AIOps on Linux. The Linux cluster must be reserved for the sole use of IBM Cloud Pak for AIOps, and you must have a minimum of three control planes nodes.
- Local storage is configured in accordance with the instructions in Configuring local volumes.
- You have the credentials for the root user. Root user must be used to install IBM Cloud Pak for AIOps.
- The worker nodes and the client machine that you are running the installation from have network connectivity to the control plane nodes.
- You have a load balancer configured in accordance with the details in Load balancing.

Important: If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

Installation Procedure

The installation procedure requires you to download the **aiopsctl** tool, which installs IBM Cloud Pak for AIOps and its prerequisites on your cluster.

1. Retrieve your entitlement key
2. Optionally configure a custom certificate
3. Create environment variables
4. Install the **aiopsctl** tool and register cluster nodes
5. Install IBM Cloud Pak for AIOps
6. Verify your installation
7. Access the Cloud Pak for AIOps console

1. Retrieve your entitlement key

Obtain the IBM entitlement key that is assigned to your **IBMid**. The key is needed to pull the IBM Cloud Pak for AIOps images from the IBM® Entitled Registry.

1. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
2. In the *Entitlement key* section, select **Copy** to copy the entitlement key to the clipboard.

2. Optionally configure a custom certificate

If you want to use your own custom certificate for IBM Cloud Pak for AIOps instead of the default cluster certificate, then use the following steps to create a certificate and key that you can supply as parameters at installation time.

1. Ensure that you have the following three PEM-encoded X.509 certificate files:
   - **caintermediate.pem**: The intermediate certificate that issued your server certificate.
   - **aiops.pem**: An IBM Cloud Pak for AIOps certificate, which includes the two fully qualified domain names (FQDNs) for **aiops-cpd** and **cp-console-aiops** in the Subject Alternative Name (SAN) list.
   - **aiops.key.pem**: A key file for the signed certificate in aiops.pem

   Tip: You can create the FQDN strings to use for **aiops-cpd** and **cp-console-aiops** by prepending **cp-console-aiops** and **aiops-cpd** to your load balancer's host name. For example, if your load balancer host name is **loadbalancerhost.acme.com**, then the FQDN strings are **cp-console-aiops.loadbalancerhost.acme.com** and **aiops-cpd.loadbalancerhost.acme.com**.
2. Concatenate the server and intermediate certificates into one file called **aiops-certificate-chain.pem**.

   ```
   cat aiops.pem caintermediate.pem > aiops-certificate-chain.pem
   ```

Note: If you do not install IBM Cloud Pak for AIOps with a custom certificate, you can switch to using a custom certificate after installation. For more information, see Using a custom certificate (IBM Cloud Pak for AIOps on Linux).

3. Create environment variables

Create and then source a shell script that is named *aiops_var.sh*, which defines the environment variables that are used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets **< ... >** with values for your environment. It is important that you keep this file.

For more information about choosing a deployment type, see Incremental adoption. Subject to further hardware requirements, you can update the deployment type post-install. For more information, see Updating the deployment type.

Important: If you used an alternative path for APP_STORAGE_PATH or PLATFORM_STORAGE_PATH when you set up your local storage in Configuring local volumes, then you must change the values of these environment variables accordingly.

```
#================================================================================================================
```

```
# IBM Cloud Pak for AIOps installation variables (Linux)

  "<control_plane_node_3>"
)
export WORKER_NODES=(
  "<worker_1>"
  "<worker_2>"
  "<worker_3>"
  "<worker_4>"
  "<worker_5>"
  "<worker_6>"
  "<worker_7>"
)

# ------------------------------------------------------------------------------------------------------------------------
# Incremental adoption - set your deployment type.
# Set to `extended` to install an extended deployment with log anomaly detection and ticket analysis capabilities
# Set to `base` to install a base deployment without log anomaly detection and ticket analysis capabilities
# ------------------------------------------------------------------------------------------------------------------------
export DEPLOY_TYPE="base"

# ------------------------------------------------------------------------------------------------------------------------------
--------
# Storage
# ------------------------------------------------------------------------------------------------------------------------------
--------
export APP_STORAGE_PATH="/var/lib/aiops/storage"
export PLATFORM_STORAGE_PATH="/var/lib/aiops/platform"
```

Run the following command to source your script and set the environment variables:

```
. ./aiops_var.sh
```

4. Install the `aiopsctl` tool and register cluster nodes

1. Run the following commands to install **aiopsctl** on your cluster, and then register the control plane nodes and worker nodes.

```
AIOPSCTL_TAR="aiopsctl-linux_amd64.tar.gz"
AIOPSCTL_INSTALL_URL="https://github.com/IBM/aiopsctl/releases/download/v4.8.0/${AIOPSCTL_TAR}"
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} tar xf "${AIOPSCTL_TAR}"
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} mv aiopsctl /usr/local/bin/aiopsctl

echo "Installing main control plane node ${CONTROL_PLANE_NODE}"
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node up --accept-license=${ACCEPT_LICENSE} --role=control-
plane --registry-token="${IBM_ENTITLEMENT_KEY}" --app-storage "${APP_STORAGE_PATH}" --platform-storage
"${PLATFORM_STORAGE_PATH}" --load-balancer-host="${LOAD_BALANCER_HOST}"

K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
K3S_HOST=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --server-url-only)

echo "Installing additional control plane nodes"
for CP_NODE in "${ADDITIONAL_CONTROL_PLANE_NODES[@]}"; do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} tar xvf "${AIOPSCTL_TAR}"
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} mv aiopsctl /usr/local/bin/aiopsctl
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} aiopsctl cluster node up --accept-
license=${ACCEPT_LICENSE} --role=control-plane --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --registry-
token="${IBM_ENTITLEMENT_KEY}" --app-storage "${APP_STORAGE_PATH}" --platform-storage "${PLATFORM_STORAGE_PATH}" --
load-balancer-host="${LOAD_BALANCER_HOST}"
done

echo "Installing worker nodes"
K3S_LB_HOST="https://${LOAD_BALANCER_HOST}:6443"
for WORKER_NODE in "${WORKER_NODES[@]}"; do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
```

```
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} tar xvf "${AIOPSCTL_TAR}"
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} mv aiopsctl /usr/local/bin/aiopsctl
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node up --accept-
license=${ACCEPT_LICENSE} --role=worker --server-url="${K3S_LB_HOST}" --token="${K3S_TOKEN}" --registry-
token="${IBM_ENTITLEMENT_KEY}" --app-storage "${APP_STORAGE_PATH}"
done
```

Note: The preceding commands install the Red Hat OpenShift CLI (oc) if it is not already installed. If it is already installed, then you must ensure that it is at version 4.14 or higher.

2. Run the following command to see information about your cluster:

   ```
   aiopsctl cluster node info
   ```

   Example output:

   ```
   #  aiopsctl cluster node info
   Node Details
   Role: Control plane
   Server URL: https://test-server.acme.com:6443
   Token: ***** (Use --show-secrets to reveal token)
   ```

3. Check for network connectivity issues.

   VMWare vSphere virtual machines (VMs) with Red Hat® Enterprise Linux® can have connectivity issues. If you are not using vSphere VMs for your IBM Cloud Pak for AIOps deployment, then skip this step. Otherwise, run the following lookup command:

   ```
   nslookup kubernetes.default.svc.cluster.local 10.43.0.10
   ```

   If the lookup is successful, then proceed to the next step. If the lookup fails, then run the following command on each of your VMs to rectify connectivity problems:

   ```
   ethtool -K flannel.1 tx-checksum-ip-generic off
   ```

   For more information, see Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs.

5. Install IBM Cloud Pak for AIOps

Run the `aiopsctl` tool to install IBM Cloud Pak for AIOps.

If you did not configure a custom certificate in step 2 then run the following command:

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode
"${DEPLOY_TYPE}"
```

If you configured a custom certificate in step 2 then run the following command:

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode
"${DEPLOY_TYPE}" --certificate-file aiops-certificate-chain.pem --key-file aiops.key.pem
```

6. Verify your installation

The installation takes one to two hours to complete. If the installation is unsuccessful, an error message is displayed and a nonzero exit code is returned.

Run the following command to check the status of the components of your IBM Cloud Pak for AIOps installation:

```
aiopsctl status
```

Example output for a healthy installation:

```
$ aiopsctl status
o- [12 Aug 24 08:40 PDT] Getting cluster status
Control Plane Node(s):
    test-server-1.acme.com Ready
    test-server-2.acme.com Ready
    test-server-3.acme.com Ready

Worker Node(s):
    test-agent-1.acme.com Ready
    test-agent-2.acme.com Ready
    test-agent-3.acme.com Ready
    test-agent-4.acme.com Ready
    test-agent-5.acme.com Ready
    test-agent-6.acme.com Ready
    test-agent-7.acme.com Ready

o- [12 Aug 24 08:40 PDT] Checking AIOps installation status

```

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

7. Access the Cloud Pak for AIOps console

Run the following command on a control plane node to see the URL, username, and password for your IBM Cloud Pak for AIOps deployment.

```
aiopsctl server info --show-secrets
```

Example output:

```
aiopsctl server info --show-secrets

Cluster Access Details
URL:      aiops-cpd.test-server.acme.com
Username: cpadmin
Password: abcdefghijklmno
```

Important: Ensure that your environment's Domain Name System (DNS) is correctly configured to resolve the hosts for accessing the Cloud Pak for AIOps console. For more information, see DNS requirements.

What to do next

Important: Any commands that use `oc` must be run from a control plane node.

- Define integrations and applications with Defining.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.

To uninstall your IBM Cloud Pak for AIOps on Linux deployment, follow the instructions in Uninstalling a deployment of IBM Cloud Pak for AIOps on Linux.

Offline installation of IBM Cloud Pak for AIOps on Linux (bastion host)

Learn about installing IBM Cloud Pak for AIOps on Linux in an offline environment with a bastion host.

Overview

If your Linux® cluster does not have internet access, you can still install IBM Cloud Pak® for AIOps by using an offline or air-gapped deployment. In this scenario, your air-gapped (offline) environment has a target registry, and a Linux cluster on which IBM Cloud Pak for AIOps is to be installed. The bastion host has access to the internet and to the air-gapped environment. IBM Cloud Pak for AIOps images are mirrored from the IBM Entitled Registry through the bastion server to the target registry in the offline environment. IBM Cloud Pak for AIOps can then be installed in the offline environment by using the target registry.

You can install a production deployment of IBM Cloud Pak for AIOps on a Linux platform, without installing Red Hat® OpenShift® Container Platform.

The deployment is configured to collect usage data. If you want to disable usage data collection, then you can do this post-install. For more information, see Updating usage data collection preferences.

Limitations

- Starter-size deployments are not supported.
- The following features and capabilities are only available for deployments of IBM Cloud Pak for AIOps on Red Hat OpenShift, and are not available for deployments of IBM Cloud Pak for AIOps on Linux:
  - FIPS support
  - Secure tunnel
  - Multi-zone HADR
  - IBM Cognos® Analytics integration

Before you begin

Ensure that you meet the following prerequisites:

- Your cluster meets all of the requirements that are detailed in Planning an installation of IBM Cloud Pak for AIOps on Linux. The Linux cluster must be reserved for the sole use of IBM Cloud Pak for AIOps, and you must have a minimum of three control planes nodes.
- Local storage is configured in accordance with the instructions in Configuring local volumes.
- You have the credentials for the root user. The root user must be used to install IBM Cloud Pak for AIOps.
- The bastion host and worker nodes have network connectivity to the control plane nodes.
- You have a load balancer configured in accordance with the details in Load balancing.

Important: If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

Installation Procedure

The installation procedure requires you to download the **`aiopsctl`** tool, which installs IBM Cloud Pak for AIOps and its prerequisites on your cluster.

1. Setup the mirroring environment
2. Retrieve your entitlement key
3. Optionally configure a custom certificate
4. Create environment variables
5. Mirror images
6. Install the **`aiopsctl`** tool and register cluster nodes
7. Install IBM Cloud Pak for AIOps
8. Verify your installation
9. Access the Cloud Pak for AIOps console

1. Setup the mirroring environment

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description
• `icr.io` • `cp.icr.io` • `dd0.icr.io` • `dd2.icr.io` • `dd4.icr.io` • `dd6.icr.io`	Allow access to these hosts on port 443 to enable access to the **`IBM Cloud Container Registry`**, CASE OCI artifact, and IBM Cloud Pak® foundational services catalog source.
• `dd1-icr.ibm-zh.com` • `dd3-icr.ibm-zh.com` • `dd5-icr.ibm-zh.com` • `dd7-icr.ibm-zh.com`	If you are located in China, also allow access to these hosts on port 443.
`github.com`	GitHub houses CASE files, IBM Cloud Pak tools, and scripts.
`mirror.openshift.com`	for the `oc` CLI

1.1 Download documentation and scripts for offline access

Download the Cloud Pak for AIOps 4.8.0 PDF (this documentation) so that you can access it offline.

1.2 Set up a target registry

You must have a local Docker type production-grade registry available to store the IBM Cloud Pak for AIOps images in. The registry must meet the following requirements:

- The registry must support OCI Manifests, in addition to Docker Manifest V2, schema 2.
- supports multi-architecture images.
- is accessible from the cluster nodes.
- must serve images over HTTPS.
- allows path separators in the image name.
- you have the username and password for a user who can read from and write to the registry.
- must have 143 GB of storage to hold all the software that is to be transferred to the target registry.

If you do not already have a suitable production-grade registry available, then you must install and configure one.

1.3 Prepare a bastion host

The bastion host must meet the following requirements:

- is able to connect to the internet
- is able to connect to the air-gapped environment with access to the cluster and the target registry.

2. Retrieve your entitlement key

Obtain the IBM entitlement key that is assigned to your **IBMid**. The key is needed to pull the IBM Cloud Pak for AIOps images from the IBM® Entitled Registry.

1. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
2. In the *Entitlement key* section, select **Copy** to copy the entitlement key to the clipboard.

3. Optionally configure a custom certificate

If you want to use your own custom certificate for IBM Cloud Pak for AIOps instead of the default cluster certificate, then use the following steps to create a certificate and key that you can supply as parameters at installation time.

1. Ensure that you have the following three PEM-encoded X.509 certificate files:
   - **cacintermediate.pem**: The intermediate certificate that issued your server certificate.
   - **aiops.pem**: An IBM Cloud Pak for AIOps certificate, which includes the two fully qualified domain names (FQDNs) for **aiops-cpd** and **cp-console-aiops** in the Subject Alternative Name (SAN) list.
   - **aiops.key.pem**: A key file for the signed certificate in aiops.pem

   Tip: You can create the FQDN strings to use for **aiops-cpd** and **cp-console-aiops** by prepending **cp-console-aiops** and **aiops-cpd** to your load balancer's host name. For example, if your load balancer host name is **loadbalancerhost.acme.com**, then the FQDN strings are **cp-console-aiops.loadbalancerhost.acme.com** and **aiops-cpd.loadbalancerhost.acme.com**.
2. Concatenate the server and intermediate certificates into one file called **aiops-certificate-chain.pem**.

   ```
   cat aiops.pem cacintermediate.pem > aiops-certificate-chain.pem
   ```

Note: If you do not install IBM Cloud Pak for AIOps with a custom certificate, you can switch to using a custom certificate after installation. For more information, see Using a custom certificate (IBM Cloud Pak for AIOps on Linux).

4. Create environment variables

Create and then source a shell script that is named *aiops_var.sh*, which defines the environment variables that are used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets **< ... >** with values for your environment. It is important that you keep this file.

For more information about choosing a deployment type, see Incremental adoption. Subject to further hardware requirements, you can update the deployment type post-install. For more information, see Updating the deployment type.

Important: If you used an alternative path for APP_STORAGE_PATH or PLATFORM_STORAGE_PATH when you set up your local storage in Configuring local volumes, then you must change the values of these environment variables accordingly.

```
#============================================================================================================================================
# IBM Cloud Pak for AIOps installation variables (Linux)
#============================================================================================================================================
export TARGET_USER="root"
export ACCEPT_LICENSE=false # Set to true to agree to the license terms.

# ------------------------------------------------------------------------------------------------------------------------------------
# IBM Entitled Registry
# ------------------------------------------------------------------------------------------------------------------------------------
export IBM_ENTITLEMENT_KEY=<ibm-entitlement-key> # Set to the entitlement key retrieved in previous step.

# ------------------------------------------------------------------------------------------------------------------------------------
# Hostnames
# `<load_balancer_hostname>` - the hostname of your load balancer
# `<control_plane_node_n>` - the FQDN or IP address of each control plane node. For example, "control_plane_node_1.example.com"
# `<worker-n>` - the FQDN or IP address of each worker node. For example, "worker_1.example.com"
# ------------------------------------------------------------------------------------------------------------------------------------
export LOAD_BALANCER_HOST="<load_balancer_hostname>"
export CONTROL_PLANE_NODE="<control_plane_node_1>"
export ADDITIONAL_CONTROL_PLANE_NODES=(
  "<control_plane_node_2>"
  "<control_plane_node_3>"
)
export WORKER_NODES=(
  "<worker_1>"
  "<worker_2>"
  "<worker_3>"
  "<worker_4>"
  "<worker_5>"
  "<worker_6>"
  "<worker_7>"
)

# ------------------------------------------------------------------------------------------------------------------------------------
# Incremental adoption - set your deployment type.
# Set to `extended` to install an extended deployment with log anomaly detection and ticket analysis capabilities
# Set to `base` to install a base deployment without log anomaly detection and ticket analysis capabilities
```

```
# ------------------------------------------------------------------------------------------------------------
export DEPLOY_TYPE="base"

# ------------------------------------------------------------------------------------------------------------
--------
# Storage
# ------------------------------------------------------------------------------------------------------------
--------
export APP_STORAGE_PATH="/var/lib/aiops/storage"
export PLATFORM_STORAGE_PATH="/var/lib/aiops/platform"

# ------------------------------------------------------------------------------------------------------------
--------
# Variables for offline installation
# If you need to specify a custom path for your target registry, then export TARGET_REGISTRY with a custom path. For
example:
# export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT/my/custom/path
# ------------------------------------------------------------------------------------------------------------
--------
export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
export TARGET_REGISTRY_USER=<your-registry-username>
export TARGET_REGISTRY_PASSWORD=<your-registry-password>
export SKIP_TLS=false # Set to true if your target registry does not provide a signed TLS certificate
```

Run the following command to source your script and set the environment variables:

```
. ./aiops_var.sh
```

5. Mirror images

1. Connect your bastion host to the internet and disconnect it from the air-gapped environment.
2. Run the following commands to download the **aiopsctl** tool and its prerequisites.

   ```
   AIOPSCTL_TAR="aiopsctl-linux_amd64.tar.gz"
   AIOPSCTL_INSTALL_URL="https://github.com/IBM/aiopsctl/releases/download/v4.8.0/${AIOPSCTL_TAR}"
   curl -LO "${AIOPSCTL_INSTALL_URL}"
   tar xf "${AIOPSCTL_TAR}"
   mv aiopsctl /usr/local/bin/aiopsctl

   aiopsctl bastion login cp.icr.io -u cp -p ${IBM_ENTITLEMENT_KEY}
   aiopsctl bastion login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD} --insecure-skip-
   tls-verify="${SKIP_TLS}"
   unset IBM_ENTITLEMENT_KEY

   aiopsctl bastion mirror-images --registry ${TARGET_REGISTRY}
   ```

   You can use the following command to monitor the mirroring process:

   ```
   tail -f /root/.aiopsctl/logs/aiopsctl.log
   ```

3. Disconnect the bastion host from the internet, and connect it to the air-gapped environment.

6. Install the `aiopsctl` tool and register cluster nodes

1. Run the following commands to install **aiopsctl** on your offline cluster, and then register the control plane nodes and worker nodes.

   ```
   scp /usr/local/bin/aiopsctl ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/aiopsctl

   if [ "$(command -v "oc")"  ]; then
     scp "$(command -v "oc")" ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/oc
   else
     scp ~/.aiopsctl/mirror/oc ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/oc
   fi

   echo "Installing main control plane node ${CONTROL_PLANE_NODE}"

   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node up --accept-license=${ACCEPT_LICENSE} --role=control-
   plane --registry="${TARGET_REGISTRY}" --registry-user="${TARGET_REGISTRY_USER}" --registry-
   token="${TARGET_REGISTRY_PASSWORD}" --offline --insecure-skip-tls-verify="${SKIP_TLS}" --app-storage
   "${APP_STORAGE_PATH}" --platform-storage "${PLATFORM_STORAGE_PATH}" --load-balancer-host="${LOAD_BALANCER_HOST}"

   # Configure kubeconfig for oc CLI
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} "mkdir -p ~/.kube && ln -s /etc/rancher/k3s/k3s.yaml ~/.kube/config"

   K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
   K3S_HOST=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --server-url-only)

   echo "Installing additional control plane nodes"
   for CP_NODE in "${ADDITIONAL_CONTROL_PLANE_NODES[@]}"; do
     ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl
   ${TARGET_USER}@${CP_NODE}:/usr/local/bin/aiopsctl
     ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} aiopsctl cluster node up --accept-
   license=${ACCEPT_LICENSE} --role=control-plane --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --
   registry="${TARGET_REGISTRY}" --registry-user="${TARGET_REGISTRY_USER}" --registry-
   token="${TARGET_REGISTRY_PASSWORD}" --offline --app-storage "${APP_STORAGE_PATH}" --platform-storage
   "${PLATFORM_STORAGE_PATH}" --load-balancer-host="${LOAD_BALANCER_HOST}"
   ```

```
done

echo "Installing worker nodes"
K3S_LB_HOST="https://${LOAD_BALANCER_HOST}:6443"
for WORKER_NODE in "${WORKER_NODES[@]}"
do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl
${TARGET_USER}@${WORKER_NODE}:/usr/local/bin/aiopsctl
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node up --accept-
license=${ACCEPT_LICENSE} --role=worker --server-url="${K3S_LB_HOST}" --token="${K3S_TOKEN}" --
registry="${TARGET_REGISTRY}" --registry-user="${TARGET_REGISTRY_USER}" --registry-
token="${TARGET_REGISTRY_PASSWORD}" --app-storage "${APP_STORAGE_PATH}" --offline --insecure-skip-tls-
verify="${SKIP_TLS}"
done
```

Note: The preceding commands install the Red Hat OpenShift CLI (oc) if it is not already installed. If it is already installed, then you must ensure that it is at version 4.14 or higher.

2. Run the following command to see information about your cluster:

   ```
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info
   ```

   Example output:

   ```
   # ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info
   Node Details
   Role: Control plane
   Server URL: https://test-server.acme.com:6443
   Token: ***** (Use --show-secrets to reveal token)
   ```

3. Check for network connectivity issues.

   VMWare vSphere virtual machines (VMs) with Red Hat® Enterprise Linux® can have connectivity issues. If you are not using vSphere VMs for your IBM Cloud Pak for AIOps deployment, then skip this step. Otherwise, run the following lookup command:

   ```
   nslookup kubernetes.default.svc.cluster.local 10.43.0.10
   ```

   If the lookup is successful, then proceed to the next step. If the lookup fails, then run the following command on each of your VMs to rectify connectivity problems:

   ```
   ethtool -K flannel.1 tx-checksum-ip-generic off
   ```

   For more information, see Installation on Linux fails with network connectivity errors when using `aiopsctl` to install on vSphere VMs.

7. Install IBM Cloud Pak for AIOps

Run the `aiopsctl` tool to install IBM Cloud Pak for AIOps.

If you did not configure a custom certificate in step 3 then run the following command:

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode
"${DEPLOY_TYPE}"
```

If you configured a custom certificate in step 3 then run the following command:

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode
"${DEPLOY_TYPE}" --certificate-file aiops-certificate-chain.pem --key-file aiops.key.pem
```

8. Verify your installation

The installation takes one to two hours to complete. If the installation is unsuccessful, an error message is displayed and a nonzero exit code is returned.

Run the following command to check the status of the components of your IBM Cloud Pak for AIOps installation:

```
aiopsctl status
```

Example output for a healthy installation:

```
$ aiopsctl status
o- [12 Aug 24 08:40 PDT] Getting cluster status
Control Plane Node(s):
    test-server-1.acme.com Ready
    test-server-2.acme.com Ready
    test-server-3.acme.com Ready

Worker Node(s):
    test-agent-1.acme.com Ready
    test-agent-2.acme.com Ready
    test-agent-3.acme.com Ready
    test-agent-4.acme.com Ready
    test-agent-5.acme.com Ready
    test-agent-6.acme.com Ready
    test-agent-7.acme.com Ready

o- [12 Aug 24 08:40 PDT] Checking AIOps installation status

  15 Ready Components
```

```
    cluster
    aimanager
    lifecycletrigger
    aiopsanalyticsorchestrator
    baseui
    elasticsearchcluster

    asm
    zenservice
    aiopsui
    commonservice
    kafka
    issueresolutioncore
    lifecycleservice

  AIOps installation healthy
```

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

9. Access the Cloud Pak for AIOps console

Run the following command on a control plane node to see the URL, username, and password for your IBM Cloud Pak for AIOps deployment.

```
aiopsctl server info --show-secrets
```

Example output:

```
aiopsctl server info --show-secrets

Cluster Access Details
URL:      aiops-cpd.test-server.acme.com
Username: cpadmin
Password: abcdefghijklmno
```

Important: Ensure that your environment's Domain Name System (DNS) is correctly configured to resolve the hosts for accessing the Cloud Pak for AIOps console. For more information, see DNS requirements.

What to do next

Important: Any commands that use `oc` must be run from a control plane node.

- Define integrations and applications with Defining.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.

To uninstall your IBM Cloud Pak for AIOps on Linux deployment, follow the instructions in Uninstalling a deployment of IBM Cloud Pak for AIOps on Linux.

Online upgrade of IBM Cloud Pak for AIOps on Linux

Use these instructions to upgrade an online deployment of IBM Cloud Pak® for AIOps 4.7.0 or later to 4.8.0.

Overview

This procedure is for deployments of IBM Cloud Pak for AIOps on Linux®. This procedure can be used on an online deployment of IBM Cloud Pak for AIOps 4.7.0 or later, and can still be used if the deployment has hotfixes applied.

You cannot use these instructions to upgrade deployments of IBM Cloud Pak for AIOps 4.6.1 or earlier. Upgrade of deployments of IBM Cloud Pak® for AIOps on Linux older than 4.7.0 is not supported. If you have a deployment of IBM Cloud Pak for AIOps older than 4.7.0, then you must uninstall it and then install 4.8.0.

If you have an offline deployment of IBM Cloud Pak for AIOps on Linux, follow the instructions in Offline upgrade of IBM Cloud Pak for AIOps on Linux.

If you have a deployment of IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform, follow the instructions in Upgrading IBM Cloud Pak for AIOps on OpenShift.

Before you begin

Ensure that you meet the following prerequisites:

- The worker nodes and the client machine that you are running the upgrade from have network connectivity to the control plane nodes.
- You have the credentials for the root user. Root user must be used to upgrade IBM Cloud Pak for AIOps.

Warnings:

- Custom patches, labels, and manual adjustments to IBM Cloud Pak for AIOps resources are lost when IBM Cloud Pak for AIOps is upgraded, and must be manually reapplied after upgrade. For more information, see Manual adjustments are not persisted.
- The upgrade cannot be removed or rolled back.

Upgrade procedure

Follow these steps to upgrade your online IBM Cloud Pak for AIOps deployment.

1. Ensure cluster readiness
2. Update the aiopsctl tool on the cluster nodes
3. Upgrade IBM Cloud Pak for AIOps
4. Verify your deployment
5. Post upgrade actions

1. Ensure cluster readiness

Recommended: Take a backup of IBM Cloud Pak for AIOps before you upgrade to v4.8.0. For more information, see Back up and restore (IBM Cloud Pak for AIOps on Linux).

1. Ensure that your cluster still meets all the prerequisites for deployment. For more information, see Planning an installation of IBM Cloud Pak for AIOps on Linux.
2. Set environment variables.
    1. Set an environment variable for your deployment mode.

        From IBM Cloud Pak for AIOps 4.8.0, deployment mode is configured with a command line argument instead of with a configuration file.

        Edit the **aiops_var.sh** file that you created when you installed IBM Cloud Pak for AIOps, and update the **DEPLOY_TYPE** environment variable to the required value. Set to **extended** if you have an extended deployment with log anomaly detection and ticket analysis capabilities, or set to **base** if you have a base deployment without log anomaly detection and ticket analysis capabilities.

    2. Run the following command from the directory that the script is in, to set the environment variables that are used later.

        ```
        . ./aiops_var.sh
        ```

    Note: If you do not still have **aiops_var.sh** from when you installed IBM Cloud Pak for AIOps, then follow the instructions in Create environment variables.
3. Delete any evicted **connector-orchestrator** pods.
    1. Run the following command to check whether there are any evicted **connector-orchestrator** pods.

        ```
        ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} oc get pods -n aiops | grep connector-orchestrator
        ```

    2. Cleanup any evicted connector-orchestrator pods.

        If the previous command returned any pods with a *STATUS* of **Evicted**, then run the following command to delete each of them.

        ```
        ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} oc delete pod -n aiops <connector_orchestrator>
        ```

        Where **<connector_orchestrator>** is a pod returned by the previous step.
4. Run the following command to ensure the safety of the Postgres database during upgrade.

    Important: Failure to run this step might lead to a complete loss of data.

    ```
    ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} oc label clusters.postgresql.k8s.enterprisedb.io -n aiops aiops-installation-edb-postgres operator.ibm.com/opreq-do-not-uninstall='true'
    ```

2. Update the aiopsctl tool on the cluster nodes

Run the following commands to update the **aiopsctl** tool on all the cluster nodes.

Note: When the command to update the first control plane node is run, you are prompted whether you want to accept the upgrade. Subsequent nodes use the **-y** flag to bypass this prompt.

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl update --version v4.8.0

echo "Upgrading main control plane node ${CONTROL_PLANE_NODE}"
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node up --accept-license=${ACCEPT_LICENSE} --role=control-plane

echo "Upgrading additional control plane nodes"
for CP_NODE in "${ADDITIONAL_CONTROL_PLANE_NODES[@]}"; do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} aiopsctl update -y --version v4.8.0
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} aiopsctl cluster node up -y --accept-license=${ACCEPT_LICENSE} --role=control-plane
done

echo "Upgrading worker nodes"
for WORKER_NODE in "${WORKER_NODES[@]}"; do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl update -y --version v4.8.0
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node up -y --accept-license=${ACCEPT_LICENSE} --role=worker
done
```

3. Upgrade IBM Cloud Pak for AIOps

Run the following command to upgrade IBM Cloud Pak for AIOps to v4.8.0.

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode
"${DEPLOY_TYPE}"
```

Note: You are prompted whether you want to accept the upgrade.

4. Verify your deployment

The upgrade takes around an hour to complete. If the upgrade is unsuccessful, an error message is displayed and a nonzero exit code is returned.

1. Check the status of your deployment.

   Run the following command to check the status of the components of your IBM Cloud Pak for AIOps installation:

   ```
   aiopsctl status
   ```

   Example output for a healthy deployment:

   ```
   $ aiopsctl status
   o- [12 Aug 24 08:40 PDT] Getting cluster status
   Control Plane Node(s):
       test-server-1.acme.com Ready
       test-server-2.acme.com Ready
       test-server-3.acme.com Ready

   Worker Node(s):
       test-agent-1.acme.com Ready
       test-agent-2.acme.com Ready
       test-agent-3.acme.com Ready
       test-agent-4.acme.com Ready
       test-agent-5.acme.com Ready
       test-agent-6.acme.com Ready
       test-agent-7.acme.com Ready

   o- [12 Aug 24 08:40 PDT] Checking AIOps installation status

     15 Ready Components
       cluster
       aimanager
       lifecycletrigger
       aiopsanalyticsorchestrator
       baseui
       elasticsearchcluster
       aiopsedge
       rediscp
       asm
       zenservice
       aiopsui
       commonservice
       kafka
       issueresolutioncore
       lifecycleservice

     AIOps installation healthy
   ```

2. Run the following command and check that the VERSION that is returned is 4.8.0.

   ```
   aiopsctl server version
   ```

If the upgrade fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

5. Post upgrade actions

1. If you previously took a backup of your deployment, it is recommended that you take a new back up. For more information, see Back up and restore (IBM Cloud Pak for AIOps on Linux).
2. If the *EXPIRY_SECONDS* environment variable was set for configuring log anomaly alerts, the environment variable was not retained in the upgrade. After the upgrade is completed, set the environment variable again. For more information about setting the variable, see Configuring expiry time for log anomaly alerts.
3. If you have a metric integration configured that stops working after upgrade, then you must follow the instructions in After upgrade, a metric integration goes into a failed state.

Offline upgrade of IBM Cloud Pak for AIOps on Linux

Use these instructions to upgrade an offline deployment of IBM Cloud Pak® for AIOps 4.7.0 or later to 4.8.0.

Overview

This procedure is for deployments of IBM Cloud Pak for AIOps on Linux®. This procedure can be used on an online deployment of IBM Cloud Pak for AIOps 4.7.0 or later, and can still be used if the deployment has hotfixes applied.

You cannot use these instructions to upgrade deployments of IBM Cloud Pak for AIOps 4.6.1 or earlier. Upgrade of deployments of IBM Cloud Pak® for AIOps on Linux older than 4.7.0 is not supported. If you have a deployment of IBM Cloud Pak for AIOps older than 4.7.0, then you must uninstall it and then install 4.8.0.

If you have an online deployment of IBM Cloud Pak for AIOps on Linux, follow the instructions in Online upgrade of IBM Cloud Pak for AIOps on Linux.

If you have a deployment of IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform, follow the instructions in Upgrading IBM Cloud Pak for AIOps on OpenShift.

Before you begin

Ensure that you meet the following prerequisites:

- The worker nodes and the client machine that you are running the upgrade from have network connectivity to the control plane nodes.
- You have the credentials for the root user. Root user must be used to upgrade IBM Cloud Pak for AIOps.

Warnings:

- Custom patches, labels, and manual adjustments to IBM Cloud Pak for AIOps resources are lost when IBM Cloud Pak for AIOps is upgraded, and must be manually reapplied after upgrade. For more information, see Manual adjustments are not persisted.
- The upgrade cannot be removed or rolled back.

Upgrade procedure

Follow these steps to upgrade your offline IBM Cloud Pak for AIOps deployment.

1. Ensure cluster readiness
2. Mirror the images
3. Update the aiopsctl tool on the cluster nodes
4. Upgrade IBM Cloud Pak for AIOps
5. Verify your deployment
6. Post upgrade actions

1. Ensure cluster readiness

Recommended: Take a backup of IBM Cloud Pak for AIOps before you upgrade to v4.8.0. For more information, see Back up and restore (IBM Cloud Pak for AIOps on Linux).

1. Ensure that your cluster still meets all of the prerequisites for an air-gapped deployment. For more information, see Planning an installation of IBM Cloud Pak for AIOps on Linux and Set up the mirroring environment.
2. Set environment variables.
    1. Set an environment variable for your deployment mode.

        From IBM Cloud Pak for AIOps 4.8.0, deployment mode is configured with a command line argument instead of with a configuration file.

        Edit the **`aiops_var.sh`** file that you created when you installed IBM Cloud Pak for AIOps, and update the **`DEPLOY_TYPE`** environment variable to the required value. Set to **`extended`** if you have an extended deployment with log anomaly detection and ticket analysis capabilities, or set to **`base`** if you have a base deployment without log anomaly detection and ticket analysis capabilities.
    2. Run the following command from the directory that the script is in, to set the environment variables that are used later.

        ```
        . ./aiops_var.sh
        ```

    Note: If you do not still have **`aiops_var.sh`** from when you installed IBM Cloud Pak for AIOps, then follow the instructions in Create environment variables.
3. Delete any evicted **`connector-orchestrator`** pods.
    1. Run the following command to check whether there are any evicted **`connector-orchestrator`** pods.

        ```
        ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} oc get pods -n aiops | grep connector-orchestrator
        ```
    2. Cleanup any evicted connector-orchestrator pods.

        If the previous command returned any pods with a *STATUS* of **`Evicted`**, then run the following command to delete each of them.

        ```
        ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} oc delete pod -n aiops <connector_orchestrator>
        ```

        Where **`<connector_orchestrator>`** is a pod returned by the previous step.
4. Run the following command to ensure the safety of the Postgres database during upgrade.

    Important: Failure to run this step might lead to a complete loss of data.

    ```
    ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} oc label clusters.postgresql.k8s.enterprisedb.io -n aiops aiops-installation-edb-postgres operator.ibm.com/opreq-do-not-uninstall='true'
    ```

2. Mirror the images

1. Connect your bastion host to the internet and disconnect it from the air-gapped environment.
2. Run the following commands to download the new version of the **aiopsctl** tool and mirror the new images.

```
AIOPSCTL_TAR="aiopsctl-linux_amd64.tar.gz"
AIOPSCTL_INSTALL_URL="https://github.com/IBM/aiopsctl/releases/download/v4.8.0/${AIOPSCTL_TAR}"
curl -LO "${AIOPSCTL_INSTALL_URL}"
tar xf "${AIOPSCTL_TAR}"
mv aiopsctl /usr/local/bin/aiopsctl

aiopsctl bastion login cp.icr.io -u cp -p ${IBM_ENTITLEMENT_KEY}
aiopsctl bastion login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD} --insecure-skip-
tls-verify="${SKIP_TLS}"
unset IBM_ENTITLEMENT_KEY

aiopsctl bastion mirror-images --registry ${TARGET_REGISTRY}
```

   You can use the following command to monitor the mirroring process:

```
tail -f /root/.aiopsctl/logs/aiopsctl.log
```

3. Disconnect the bastion host from the internet, and connect it to the air-gapped environment.

3. Update the aiopsctl tool on the cluster nodes

Run the following commands to update the **aiopsctl** tool on all the cluster nodes.

Note: When the command to update the first control plane node is run, you are prompted whether you want to accept the upgrade. Subsequent nodes use the **-y** flag to bypass this prompt.

```
scp /usr/local/bin/aiopsctl ${TARGET_USER}@${CONTROL_PLANE_NODE}:/usr/local/bin/aiopsctl

echo "Upgrading main control plane node ${CONTROL_PLANE_NODE}"

ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node up --accept-license=${ACCEPT_LICENSE} --role=control-plane
--offline

echo "Upgrading additional control plane nodes"
for CP_NODE in "${ADDITIONAL_CONTROL_PLANE_NODES[@]}"; do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl ${TARGET_USER}@${CP_NODE}:/usr/local/bin/aiopsctl
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${CP_NODE} aiopsctl cluster node up --accept-
license=${ACCEPT_LICENSE} -y --role=control-plane --offline
done

echo "Upgrading worker nodes"
for WORKER_NODE in "${WORKER_NODES[@]}"
do
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl
${TARGET_USER}@${WORKER_NODE}:/usr/local/bin/aiopsctl
  ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node up --accept-
license=${ACCEPT_LICENSE} -y --role=worker --offline
done
```

4. Upgrade IBM Cloud Pak for AIOps

Run the following command to upgrade IBM Cloud Pak for AIOps to v4.8.0.

```
ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode
"${DEPLOY_TYPE}"
```

Note: You are prompted whether you want to accept the upgrade.

5. Verify your deployment

The upgrade takes around an hour to complete. If the upgrade is unsuccessful, an error message is displayed and a nonzero exit code is returned.

1. Check the status of your deployment.

   Run the following command to check the status of the components of your IBM Cloud Pak for AIOps installation:

```
aiopsctl status
```

   Example output for a healthy deployment:

```
$ aiopsctl status
o- [12 Aug 24 08:40 PDT] Getting cluster status
Control Plane Node(s):
    test-server-1.acme.com Ready
    test-server-2.acme.com Ready
    test-server-3.acme.com Ready

Worker Node(s):
    test-agent-1.acme.com Ready
    test-agent-2.acme.com Ready
```

```
    test-agent-3.acme.com Ready
    test-agent-4.acme.com Ready
    test-agent-5.acme.com Ready
    test-agent-6.acme.com Ready
    test-agent-7.acme.com Ready

o- [12 Aug 24 08:40 PDT] Checking AIOps installation status

  15 Ready Components
    cluster
    aimanager
    lifecycletrigger
    aiopsanalyticsorchestrator
    baseui
    elasticsearchcluster
    aiopsedge
    rediscp
    asm
    zenservice
    aiopsui
    commonservice
    kafka
    issueresolutioncore
    lifecycleservice

  AIOps installation healthy
```

2. Run the following command and check that the VERSION that is returned is 4.8.0.

```
aiopsctl server version
```

If the upgrade fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

6. Post upgrade actions

1. If you previously took a backup of your deployment, it is recommended that you take a new back up. For more information, see Back up and restore (IBM Cloud Pak for AIOps on Linux).
2. If the *EXPIRY_SECONDS* environment variable was set for configuring log anomaly alerts, the environment variable was not retained in the upgrade. After the upgrade is completed, set the environment variable again. For more information about setting the variable, see Configuring expiry time for log anomaly alerts.
3. If you have a metric integration configured that stops working after upgrade, then you must follow the instructions in After upgrade, a metric integration goes into a failed state.

Administering IBM Cloud Pak for AIOps on Linux

After you install IBM Cloud Pak® for AIOps, you can access several options for administering and customizing your deployment.

- Adding a control plane node
- Adding a worker node
- Backup and restore
- Configuring topology resources for production
- Recovering from node failure
- Removing a node
- Resizing storage
- Restarting the environment
- Updating the deployment type
- Using a custom certificate

See also Cloud Pak administration

To gather data about your deployment for support or troubleshooting purposes, you can install and run the **`MustGather`** script:

- MustGather tool

Adding a control plane node (IBM Cloud Pak for AIOps on Linux)

Learn how to add a control plane node to a Linux® cluster that has a deployment of IBM Cloud Pak® for AIOps running on it.

Procedure

1. Set environment variables.

1. Run the following command to source the shell script **aiops_var.sh** that you created when you installed IBM Cloud Pak for AIOps on your Linux cluster.

   ```
   . ./aiops_var.sh
   ```

   For more information about **aiops_var.sh**, see *Create environment variables* in Online installation of IBM Cloud Pak for AIOps on Linux or Offline installation of IBM Cloud Pak for AIOps on Linux.

2. Set an environment variable for the new control plane node that you want to add.

   ```
   export NEW_CP_NODE="<new_cp_node>"
   ```

   Where **<new_cp_node>** is the FQDN or IP address of the control plane node to be added, for example **test-server4.acme.com**.

3. If the main control plane node is down or offline, then run the following command:

   ```
   export CONTROL_PLANE_NODE="<other_cp_node>"
   ```

   Where **<other_cp_node>** is the FQDN or IP address of a working control plane node that is an entry in the **ADDITIONAL_CONTROL_PLANE_NODES** array in **aiops_var.sh**.

2. Configure a new control plane node.

   Run the commands in one of the following codeblocks, depending on whether your deployment is online or offline.

   Online deployments

   ```
   K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
   K3S_HOST=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --server-url-only)

   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_CP_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_CP_NODE} tar xvf "${AIOPSCTL_TAR}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_CP_NODE} mv aiopsctl /usr/local/bin/aiopsctl
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_CP_NODE} aiopsctl cluster node up --accept-
   license=${ACCEPT_LICENSE} --role=control-plane --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --registry-
   token="${IBM_ENTITLEMENT_KEY}" --app-storage "${APP_STORAGE_PATH}" --platform-storage "${PLATFORM_STORAGE_PATH}" --
   load-balancer-host="${LOAD_BALANCER_HOST}"
   ```

   Offline deployments

   Run the following commands from your bastion host:

   ```
   K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
   K3S_HOST=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --server-url-only)

   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl
   ${TARGET_USER}@${NEW_CP_NODE}:/usr/local/bin/aiopsctl
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_CP_NODE} aiopsctl cluster node up --accept-
   license=${ACCEPT_LICENSE} --role=control-plane --server-url="${K3S_HOST}" --token="${K3S_TOKEN}"
   registry="${TARGET_REGISTRY}" --registry-user="${TARGET_REGISTRY_USER}" --registry-
   token="${TARGET_REGISTRY_PASSWORD}"  --app-storage "${APP_STORAGE_PATH}" --platform-storage
   "${PLATFORM_STORAGE_PATH}" --load-balancer-host="${LOAD_BALANCER_HOST}"
   ```

3. Update the environment variables script **aiops_var.sh**. This is to maintain the accuracy of the environment variables file.

   When your new control plane node is succesfully added and configured, update the **aiops_var.sh** file.

   - If you added the new control plane node as an additional control plane node, then add an entry for it to the **ADDITIONAL_CONTROL_PLANES** array.
   - If you added the new control plane node as the main control plane node, then set the value of **CONTROL_PLANE_NODE** to be your new control plane node.

4. Update your load balancer's configuration for the control plane node that you just added.

Adding a worker node (IBM Cloud Pak for AIOps on Linux)

Learn how to add a worker node to a Linux® cluster that has a deployment of IBM Cloud Pak® for AIOps running on it.

Procedure

1. Set environment variables.

   1. Run the following command to source the shell script **aiops_var.sh** that you created when you installed IBM Cloud Pak for AIOps on your Linux cluster.

      ```
      . ./aiops_var.sh
      ```

      For more information about **aiops_var.sh**, see *Create environment variables* in Online installation of IBM Cloud Pak for AIOps on Linux or Offline installation of IBM Cloud Pak for AIOps on Linux.

   2. Set an environment variable for the new worker node that you want to add.

      ```
      export NEW_WORKER_NODE="<new_worker_node>"
      ```

      Where **<new_worker_node>** is the FQDN or IP address of the worker node to be added, for example **agent8.acme.com**.

2. Run the following commands to configure your new worker node.

   For online deployments:

   ```
   K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
   K3S_HOST="https://${LOAD_BALANCER_HOST}:6443"

   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_WORKER_NODE} curl -LO "${AIOPSCTL_INSTALL_URL}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_WORKER_NODE} tar xvf "${AIOPSCTL_TAR}"
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_WORKER_NODE} mv aiopsctl /usr/local/bin/aiopsctl
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_WORKER_NODE} aiopsctl cluster node up --accept-
   license=${ACCEPT_LICENSE} --role=worker --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --registry-
   token="${IBM_ENTITLEMENT_KEY}" --app-storage "${APP_STORAGE_PATH}"
   ```

   For offline deployments:

   ```
   K3S_TOKEN=$(ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster node info --token-only)
   K3S_HOST="https://${LOAD_BALANCER_HOST}:6443"

   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp -r ~/.aiopsctl ${TARGET_USER}@${NEW_WORKER_NODE}:~/.aiopsctl/
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} scp /usr/local/bin/aiopsctl
   ${TARGET_USER}@${NEW_WORKER_NODE}:/usr/local/bin/aiopsctl
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NEW_WORKER_NODE} aiopsctl cluster node up --accept-
   license=${ACCEPT_LICENSE} --role=worker --server-url="${K3S_HOST}" --token="${K3S_TOKEN}" --
   registry="${TARGET_REGISTRY}" --registry-user="${TARGET_REGISTRY_USER}" --registry-
   token="${TARGET_REGISTRY_PASSWORD}" --app-storage "${APP_STORAGE_PATH}" --offline --insecure-skip-tls-
   verify="${SKIP_TLS}"
   ```

3. Update the environment variables script **aiops_var.sh**.

   When your worker node is succesfully added and configured, add an entry for it to the **WORKER_NODES** array for the new control plane node. This is to maintain the accuracy of the environment variables file.

Back up and restore (IBM Cloud Pak for AIOps on Linux)

Learn how to back up and restore a deployment of IBM Cloud Pak® for AIOps on a Linux® cluster.

Overview

The backup and restore procedure for deployments of IBM Cloud Pak for AIOps on Linux requires you to backup the virtual machines (VMs) in the cluster, and to use the VM backups for restoration as necessary. This procedure can be used for online and offline deployments of IBM Cloud Pak for AIOps.

The restore process can be used for the following scenarios:

- restore to a new cluster
- restore to the same cluster, which has missing worker or control nodes
- restore to the same cluster, which has some missing integrations, resource groups, or topology data.

The backup procedure is disruptive and requires the shutdown of the Linux cluster.

Backup

1. Shutdown the Linux cluster. Run steps 1-5 from Restart the environment. This step is mandatory - a backup can be used for restore only if it was taken after the Linux cluster was shut down.

2. Use a backup and restore tool of your choice to backup all of your VMs. If your chosen tool allows, it is recommended to group VMs together for backup (such as entire vApp backup on VMware®). This simplifies the backup process and helps ensure that all the cluster VMs are backed up consistently.

Restore

Note: The cluster that you are restoring to must have at least the same size and resources as the cluster that the backup was created on.

1. Use the backup and restore tool to restore the VMs.

2. Restart IBM Cloud Pak for AIOps. Run steps 6-8 from Restart the environment.

Configuring topology resources for production (IBM Cloud Pak for AIOps on Linux)

Learn how to configure the File observer for more than 600,000 resources.

Configuring the File observer

Additional configuration is required if you are using the File observer for more than 600,000 resources.

If IBM Sales representatives and Business Partners did not use the custom sizing tool to supply you with a custom profile ConfigMap to customize your deployment, then run the following command from a control plane node:

```
cat <<EOF | oc apply -f -
apiVersion: v1
kind: ConfigMap
metadata:
  labels:
    app.kubernetes.io/instance: aiops
    app.kubernetes.io/managed-by: ibm-aiops-orchestrator
    app.kubernetes.io/name: custom-sized-profiles
    app.kubernetes.io/part-of: ibm-aiops
    aiops-custom-size-profile-version: 4.2.0-2023
  name: aiops-custom-size-profile
data:
  # WARNING: Modifications to this ConfigMap may cause your AIOPs installation to become unstable.
  profiles: |
    generatedfor: HA
    configmaps:
    - name: aiops-topology-sizing
      data:
        asm: |
          file-observer:
            specs:
              replicas: 1
            containers:
              file-observer:
                resources:
                  requests:
                    cpu: 100m
                    memory: 750Mi
                  limits:
                    cpu: 1000m
                    memory: 1750Mi
                env:
                  - name: JVM_ARGS
                    value: -Xms300M -Xmx1400M
EOF
```

If IBM Sales representatives and Business Partners used the custom sizing tool to supply you with a custom profile ConfigMap to customize your deployment, then use the following steps to adjust the value of *JVM_ARGS* for the File observer to *-Xms300M -Xmx1400M*:

1. Log in to a control plane node and then run the following command:

   ```
   oc project aiops
   ```

2. Run the following commands to edit your custom profile configmap:

   ```
   CUSTOM_SIZE_PROFILE=$(oc get installation -n aiops -o jsonpath='{.items[0].status.customProfileConfigmap}')
   oc edit configmap "${CUSTOM_SIZE_PROFILE}" -n aiops
   ```

3. Adjust the value of *JVM_ARGS* for the File observer to *-Xms300M -Xmx1400M* and save your changes.

   Example excerpt:

   ```
   - name: aiops-topology-sizing
     data:
       asm: |
         file-observer:
           specs:
             replicas: 1
           containers:
             file-observer:
               resources:
                 requests:
                   cpu: 100m
                   memory: 750Mi
                 limits:
                   cpu: 1000m
                   memory: 1750Mi
               env:
                 - name: JVM_ARGS
                   value: -Xms300M -Xmx1400M
   ```

Recovering from node failure (IBM Cloud Pak for AIOps on Linux)

Learn about recovering from a failed worker or control plane node on a Linux® cluster that has a deployment of IBM Cloud Pak® for AIOps running on it.

Overview

IBM Cloud Pak for AIOps is highly available and able to withstand a single node failure. IBM Cloud Pak for AIOps replicates stateful and nonstateful pods and storage, and can also move nonstateful pods to alternative nodes if the node that they are scheduled on fails.

If a node in your Linux cluster fails and is inaccessible, use the procedure in this topic to delete it. Stateful pods that were on the failed node are rescheduled to alternative nodes, and data is replicated from other healthy replicas.

Note: The following procedures are also available:

- if you no longer want a node in your Linux cluster to be used by your IBM Cloud Pak for AIOps deployment, follow the instructions in Removing a node.
- if you want to uninstall IBM Cloud Pak for AIOps completely, follow the instructions in Uninstalling IBM Cloud Pak for AIOps on Linux.

Procedure

1. Run the following command to identify a failed node.

   ```
   oc get node
   ```

   A failed worker node has a *STATUS* of **NotReady** and does not have a ROLE of **control-plane.etcd.master**.

   A failed control plane node has a *STATUS* of **NotReady** and has a ROLE of **control-plane.etcd.master**.

   Example output for a Linux cluster with a failed worker node called **agent1.acme.com**.

   ```
   NAME               STATUS    ROLES                       AGE   VERSION
   agent1.acme.com    NotReady  <none>                      7d2h  v1.30.2+k3s2
   agent2.acme.com    Ready     <none>                      7d2h  v1.30.2+k3s2
   agent3.acme.com    Ready     <none>                      7d2h  v1.30.2+k3s2
   agent4.acme.com    Ready     <none>                      7d2h  v1.30.2+k3s2
   agent5.acme.com    Ready     <none>                      7d2h  v1.30.2+k3s2
   agent6.acme.com    Ready     <none>                      7d2h  v1.30.2+k3s2
   agent7.acme.com    Ready     <none>                      7d2h  v1.30.2+k3s2
   server1.acme.com   Ready     control-plane.etcd.master   7d2h  v1.30.2+k3s2
   server2.acme.com   Ready     control-plane.etcd.master   7d2h  v1.30.2+k3s2
   server3.acme.com   Ready     control-plane.etcd.master   7d2h  v1.30.2+k3s2
   ```

2. Add another node to your Linux cluster so that replicas can be distributed across the additional node.

   - If you have a failed worker node, follow the instructions in Adding a worker node.
   - If you have a failed control plane node, follow the instructions in Adding a control plane node.

3. Delete the failed node.

   Run the following command from a control plane node to delete the failed node and relocate its workloads and storage to other nodes in the cluster.

   ```
   aiopsctl cluster delete-node <node_name>
   ```

   Where **<node_name>** is the name of the failed worker or control plane node.

   You are prompted with a warning that data loss might occur, and a query whether to continue. To avoid data loss, examine the **Data stored on node** table to check that the replication of your data stores is sufficient such that data loss does not occur if you continue to delete the node. Check that the last column **Replicas remaining after deletion** does not have *0* for any row, and that an extra warning message to contact IBM Support is not displayed. Type **y** at the prompt if you want to continue.

   Example output for a cluster where it is safe to continue and remove the node:

   ```
   $ aiopsctl cluster delete-node agent1.acme.com
   [WARN] Removing node agent1.acme.com. This may cause data loss, read the information below carefully before
   continuing.

   Data stored on node:

   Name                          Total replicas  Replicas on node  Replicas remaining after deletion
   Kafka                         3               0                 3
   Identity Management Postgres  2               0                 2
   Zen MinIO                     3               1                 2
   CouchDB                       3               0                 3
   Elasticsearch                 3               0                 3
   Zen Postgres                  2               0                 2
   AIOps Postgres                3               1                 2
   AIOps MinIO                   5               0                 5
   Redis                         3               1                 2
   Cassandra                     3               0                 3

   Are you sure you wish to continue? (y/n): y

   o- [24 Jul 24 08:44 CDT] Deleting node agent1.acme.com...
   o- [24 Jul 24 08:44 CDT] Recovering datastores...

   # Node is removed
   ```

   Note: If you have only one control plane node, then you cannot delete that node, and **aiopsctl** prevents you from doing so.

4. Update the environment variables file **aiops_var.sh**.

   Edit the shell script **aiops_var.sh** that you created when you installed IBM Cloud Pak for AIOps on your Linux cluster. This is to maintain the accuracy of the environment variables file.

   For more information about **aiops_var.sh**, see *Create environment variables* in Online installation of IBM Cloud Pak for AIOps on Linux or Offline installation of IBM Cloud Pak for AIOps on Linux.

If you deleted a worker node:

Remove the entry for the deleted worker node from **aiops_var.sh**.

If you deleted a control plane node:

- If the deleted control plane node is in the ADDITIONAL_CONTROL_PLANES array, then remove the entry for the deleted control plane node.
- If the deleted control plane node is the CONTROL_PLANE_NODE, then replace the value of CONTROL_PLANE_NODE with the value of the new main control plane node that you created in step 2, if you have not already done so.

5. If you added and deleted a control plane node, then update your load balancer's configuration.

Removing a node (IBM Cloud Pak for AIOps on Linux)

Learn how to remove a worker node or a control plane node from a deployment of IBM Cloud Pak® for AIOps on Linux®.

Overview

If you no longer want a worker node or a control plane node in your Linux cluster to be used by your IBM Cloud Pak for AIOps deployment, then use the following procedure to remove it.

Note: The following procedures are also available:

- if you want to uninstall IBM Cloud Pak for AIOps completely, follow the instructions in Uninstalling IBM Cloud Pak for AIOps on Linux.
- if you want to delete and recover from a single unresponsive worker node in your IBM Cloud Pak for AIOps deployment, follow the instructions in Recovering from node failure.

Procedure

Important:

- You must check that the removal of a node will not cause there to be insufficient resources for IBM Cloud Pak for AIOps. For more information, see Planning an installation. You must always have three control plane nodes.
- If you have only one control plane node, do not remove it as this will cause IBM Cloud Pak for AIOps to stop functioning.

1. Before you remove a node, ensure that you first add a new node. For more information, see Adding a control plane node or Adding a worker node.
2. Set environment variables.
    1. Run the following command to source the shell script **aiops_var.sh** that you created when you installed IBM Cloud Pak for AIOps on your Linux cluster.

        ```
        . ./aiops_var.sh
        ```

        For more information about **aiops_var.sh**, see *Create environment variables* in Online installation of IBM Cloud Pak for AIOps on Linux or Offline installation of IBM Cloud Pak for AIOps on Linux.

    2. Set an additional temporary environment variable for the node that you are removing.

        ```
        export NODE_TO_REMOVE=<node_to_remove>
        ```

        Where **<node_to_remove>** is the FQDN or IP address of the node that you want to remove. For example, **node1.example.com**.

3. Run the following command to uninstall **k3s** on the node that you want to remove.

    ```
    ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl cluster delete-node ${NODE_TO_REMOVE}
    ```

    You are prompted with a warning that data loss might occur, and a query whether to continue. To avoid data loss, examine the **Data stored on node** table to check that the replication of your data stores is sufficient such that data loss does not occur if you continue to delete the node. Check that the last column **Replicas remaining after deletion** does not have *0* for any row, and that an extra warning message to contact IBM Support is not displayed. Type **y** at the prompt if you want to continue.

    Example output for a cluster where it is safe to continue and remove the node:

    ```
    $ aiopsctl cluster delete-node agent1.acme.com
    [WARN] Removing node agent1.acme.com. This may cause data loss, read the information below carefully before continuing.

    Data stored on node:

    Name                          Total replicas  Replicas on node  Replicas remaining after deletion
    Kafka                         3               0                 3
    Identity Management Postgres  2               0                 2
    Zen MinIO                     3               1                 2
    CouchDB                       3               0                 3
    Elasticsearch                 3               0                 3
    Zen Postgres                  2               0                 2
    AIOps Postgres                3               1                 2
    AIOps MinIO                   5               0                 5
    Redis                         3               1                 2
    Cassandra                     3               0                 3
    ```

```
Are you sure you wish to continue? (y/n): y

o- [24 Jul 24 08:44 CDT] Deleting node agent1.acme.com...
o- [24 Jul 24 08:44 CDT] Recovering datastores...

# Node is removed
```

Note: If you have only one control plane node, then you cannot delete that node, and `aiopsctl` prevents you from doing so.

4. Run one of the following commands to remove the node from your IBM Cloud Pak for AIOps deployment, depending on whether it is a worker node or a control plane node.

   Worker node:

   ```
   ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} ssh ${TARGET_USER}@${NODE_TO_REMOVE} aiopsctl cluster node down --role
   worker --app-storage ${APP_STORAGE_PATH}
   ```

   Control plane node:

   ```
   ssh ${TARGET_USER}@${NODE_TO_REMOVE} aiopsctl cluster node down --role control-plane
   ```

5. Update the environment variables file `aiops_var.sh`

   When your node is successfully removed, remove its entry from `aiops_var.sh`. This is to maintain the accuracy of the environment variables file.

   For more information about `aiops_var.sh`, see *Create environment variables* in Online installation of IBM Cloud Pak for AIOps on Linux or Offline installation of IBM Cloud Pak for AIOps on Linux.

   If you are removing a worker node:

   Remove the entry for the worker node that you removed from the WORKER_NODES array.

   If you are removing a control plane node:

   - If the control plane node that you removed is in the ADDITIONAL_CONTROL_PLANES array, then remove the entry for the control plane node from the ADDITIONAL_CONTROL_PLANES array.
   - If the control plane node that you removed is the CONTROL_PLANE_NODE, then replace the value of CONTROL_PLANE_NODE with the value of the new main control plane node that you created in step 1, if you have not already done so.

6. If you removed a control plane node, then update your load balancer's configuration.

Resizing storage (IBM Cloud Pak for AIOps on Linux)

Learn about increasing the logical storage volumes on an existing installation of IBM Cloud Pak® for AIOps on Linux®.

Note: Do not attempt to manually increase the size of your persistent volume claims (PVCs). PVC capacity limits are not relevant for deployments of IBM Cloud Pak for AIOps on Linux. Capacity is only limited by the size of your logical storage volumes.

Use your preferred method to monitor your disk usage. If you become close to running out of disk space, use the following steps to increase the volume sizes on your Linux cluster nodes as necessary:

1. Export environment variables.

   ```
   export DRIVE_NAME=<drive_name>
   export NEW_SIZE=<new_size>
   ```

   Where

   - `<drive_name>` is the name of the disk drive that was specified for IBM Cloud Pak for AIOps application storage when you set up local storage in Configuring local volumes.
   - `<new_size>` is the new increased size for the volume, in Gigabytes (G).

   For example:

   ```
   export DRIVE_NAME="/dev/vdb"
   export NEW_SIZE="199G"
   ```

2. Extend the logical volume.

   ```
   export APP_DMPATH=$(lvs --noheadings -o dmpath aiops | sed -e 's/^[[:space:]]*//')
   lvextend -L "${NEW_SIZE}" "{APP_DMPATH}"
   ```

3. Grow the file system.

   ```
   xfs_growfs "${STORAGE_PATH}"
   ```

Restarting the environment (IBM Cloud Pak for AIOps on Linux)

Learn how to shutdown and restart the Linux cluster where IBM Cloud Pak for AIOps is deployed.

Overview

Use this procedure before a known maintenance window or outage to shut down the Linux cluster where IBM Cloud Pak for AIOps is installed, and to restart the cluster and workloads afterward.

Warning: If you need to shut down the cluster where IBM Cloud Pak for AIOps is installed, then you must use the following procedure. Failure to do so can result in data loss or corruption.

Procedure

1. Validate the installation
2. Check the certificates
3. Prepare to scale down
4. Scale down the workloads and drain the nodes
5. Shut down the cluster
6. Restart the cluster
7. Scale up the workloads
8. Validate the installation

1. Validate the installation

Run the describe command:

```
kubectl describe installations.orchestrator.aiops.ibm.com -n aiops
```

Review the `ComponentStatus` fields to confirm that all components are marked as `Ready` and the phase is `Running`.

Example output:

```
Name:         ibm-cp-aiops
Namespace:    aiops
API Version:  orchestrator.aiops.ibm.com/v1alpha1
Kind:         Installation
Spec:
...
Status:
Componentstatus:
   Aimanager:                        Ready
   Aiopsanalyticsorchestrator:       Ready
   Aiopsedge:                        Ready
   Aiopsui:                          Ready
   Asm:                              Ready
   Baseui:                           Ready
   Cluster:                          Ready
   Commonservice:                    Ready
   Elasticsearch:                    Ready
   Flinkdeployment:                  Ready
   Issueresolutioncore:              Ready
   Kafka:                            Ready
   Lifecycleservice:                 Ready
   Lifecycletrigger:                 Ready
   Rediscp:                          Ready
   Tunnel:                           Ready
   Zenservice:                       Ready
Phase:                    Running
```

2. Check the certificates

Ensure that none of the certificates have problems or are expired.

Run the following command:

```
while read l; do echo "$l" | grep '^NAME' || (n=$(echo $l | sed 's/ .*//'); s=$(echo $l | sed 's/^[^ ]* *\([^
]*\).*/\1/'); x=$(kubectl get secret -n $n $s -o jsonpath='{.data.tls\.crt}' | base64 -d | openssl x509 -noout -enddate
2>/dev/null | sed 's!notAfter=!!'); echo "$l" | sed 's![^ ][^ ]*$!'"$x"'!'); done< <(kubectl get secret -A --field-
selector=type==kubernetes.io/tls -o custom-
columns=NAMESPACE:.metadata.namespace,NAME:.metadata.name,EXPIRY:.metadata.name)
```

Example output excerpt:

```
ibm-licensing   ibm-license-service-cert                                  Jan  8  13:32:07  2025  GMT
ibm-licensing   ibm-license-service-cert-internal                         Jan  7  13:31:12  2026  GMT
ibm-licensing   ibm-licensing-service-prometheus-cert                     Jan  7  13:31:25  2026  GMT
aiops           aimanager-aio-log-anomaly-feedback-learning-cert          Jan  7  14:01:43  2026  GMT
aiops           aimanager-aio-log-anomaly-golden-signals-cert             Jan  7  14:01:43  2026  GMT
aiops           aimanager-aio-oob-recommended-actions-cert                Jan  7  14:01:43  2026  GMT
<...>
```

Renew or re-create any certificates that have problems, are expired, or will expire before the cluster is restarted.

3. Prepare to scale down

1. Cordon all of the worker and control plane nodes.

   From a control plane node, run the following command for each of the worker and control plane nodes:

   ```
   kubectl cordon <node>
   ```

   Where **<node>** is the name of the node to cordon.

2. Make a note of the number of replicas.

   1. Make a note of the number of replicas for each StatefulSet.

      ```
      kubectl get statefulsets -n aiops
      ```

      Example output:

      ```
      NAME                                    READY   AGE
      aimanager-ibm-minio                     1/1     42m
      aiops-ibm-elasticsearch-es-server-all   1/1     86m
      aiops-installation-redis-server         3/3     84m
      aiops-ir-analytics-spark-worker         2/2     63m
      aiops-ir-core-ncobackup                 0/0     75m
      aiops-ir-core-ncoprimary                0/0     76m
      aiops-topology-cassandra                1/1     83m
      c-example-couchdbcluster-m              1/1     77m
      zen-minio                               3/3     76m
      ```

      Note:

      - If you do not have a IBM® Netcool® Operations Insight® probe integration, then `aiops-ir-core-ncobackup` and `aiops-ir-core-ncoprimary` has zero replicas.
      - If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb` StatefulSet.

   2. Make a note of the number of replicas for each StrimziPodSet.

      ```
      kubectl get strimzipodset -n aiops
      ```

      Example output:

      ```
      NAME                          PODS   READY PODS   CURRENT PODS   AGE
      iaf-system-kafka              3      3            3              13d
      iaf-system-zookeeper          3      3            3              13d
      ```

   3. Make a note of the number of replicas for each Flink deployment by using the following command:

      ```
      kubectl get deployment | grep flink | grep -v "operator"
      ```

      Example output:

      ```
      NAME                                    PODS   READY PODS   CURRENT PODS   AGE
      aiops-ir-lifecycle-flink                1/1     1            1             137m
      aiops-ir-lifecycle-flink-taskmanager    1/1     1            1             137m
      aiops-lad-flink                         1/1     1            1             139m
      aiops-lad-flink-taskmanager             2/2     2            2             139m
      ```

      Notes:

      - If you have a base deployment, then `aiops-lad-flink` and `aiops-lad-flink-taskmanager` do not show in the preceding output.
      - If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb` StatefulSet.

4. Scale down the workloads and drain the nodes

1. Scale down the operator deployments in the IBM Cloud Pak for AIOps namespace.

   ```
   kubectl scale deployment -l olm.owner.kind=ClusterServiceVersion -n aiops --replicas=0
   ```

   Run the following command to check that the number of replicas for each of the operator deployments is now 0.

   ```
   kubectl get deployment -n aiops -l olm.owner.kind=ClusterServiceVersion
   ```

   Example output:

   ```
   NAME                                          READY   UP-TO-DATE   AVAILABLE   AGE
   aimanager-operator-controller-manager         0/0     0            0           47m
   aiopsedge-operator-controller-manager         0/0     0            0           47m
   asm-operator                                  0/0     0            0           47m
   iaf-flink-operator-controller-manager         0/0     0            0           54m
   ibm-aiops-orchestrator-controller-manager     0/0     0            0           58m
   ibm-common-service-operator                   0/0     0            0           56m
   ibm-commonui-operator                         0/0     0            0           53m
   ibm-elastic-operator-controller-manager       0/0     0            0           54m
   ibm-events-operator-v5.0.1                    0/0     0            0           54m
   ibm-iam-operator                              0/0     0            0           54m
   ibm-ir-ai-operator-controller-manager         0/0     0            0           47m
   ibm-redis-cp-operator                         0/0     0            0           49m
   ibm-secure-tunnel-operator                    0/0     0            0           48m
   ibm-watson-aiops-ui-operator-controller-manager   0/0     0            0           48m
   ibm-zen-operator                              0/0     0            0           54m
   ```

```
ir-core-operator-controller-manager                0/0     0            0           47m
ir-lifecycle-operator-controller-manager           0/0     0            0           47m
operand-deployment-lifecycle-manager               0/0     0            0           55m
postgresql-operator-controller-manager-1-18-12     0/0     0            0           54m
```

Note: If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb-operator` deployment.

2. Scale down the StatefulSets that you noted in step 3.2.

   You can use the Cloud Pak for AIOps console, or create a shell script to do this.

   If you have a base deployment, then remove the following lines from the example shell script:

```
kubectl scale deployment aiops-lad-flink --replicas=0 -n aiops
kubectl scale deployment aiops-lad-flink-taskmanager --replicas=0 -n aiops
```

   Note:

   - If you have a base deployment, then `aiops-lad-flink` and `aiops-lad-flink-taskmanager` do not show in the preceding output.
   - If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb` StatefulSet.

   If you upgraded from an earlier version of IBM Cloud Pak for AIOps, then add the following line to the example shell script:

```
kubectl scale statefulsets icp-mongodb --replicas=0 -n aiops
```

   Example shell script:

```
#!/bin/bash

kubectl scale statefulsets aimanager-ibm-minio --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets aiops-installation-redis-server --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets aiops-ir-analytics-spark-worker --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets aiops-ir-core-ncobackup --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets aiops-ir-core-ncoprimary --replicas=0 -n aiops
sleep 2
kubectl scale deployment aiops-ir-lifecycle-flink --replicas=0 -n aiops
sleep 2
kubectl scale deployment aiops-ir-lifecycle-flink-taskmanager --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets aiops-topology-cassandra --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets c-example-couchdbcluster-m --replicas=0 -n aiops
sleep 2
kubectl scale deployment aiops-lad-flink --replicas=0 -n aiops
sleep 2
kubectl scale deployment aiops-lad-flink-taskmanager --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets aiops-ibm-elasticsearch-es-server-all --replicas=0 -n aiops
sleep 2
kubectl scale statefulsets zen-minio --replicas=0 -n aiops
sleep 2
```

   Run the following command to check that the number of replicas for each of the StatefulSets is now 0.

```
kubectl get statefulsets -n aiops
```

   Example output:

```
NAME                                    READY   AGE
aimanager-ibm-minio                     0/0     42m
aiops-ibm-elasticsearch-es-server-all   0/0     86m
aiops-installation-redis-server         0/0     84m
aiops-ir-analytics-spark-worker         0/0     63m
aiops-ir-core-ncobackup                 0/0     75m
aiops-ir-core-ncoprimary                0/0     76m
aiops-topology-cassandra                0/0     83m
c-example-couchdbcluster-m              0/0     77m
zen-minio                               0/0     76m
```

3. Run the following command to check that the number of replicas for each of the Flink Deployments is now 0.

```
kubectl get deployments -n aiops | grep flink | grep -v "operator"
```

   Example output:

```
NAME                                  READY   UP-TO-DATE   AVAILABLE   AGE
aiops-ir-lifecycle-flink              0/0     0            0           137m
aiops-ir-lifecycle-flink-taskmanager  0/0     0            0           137m
aiops-lad-flink                       0/0     0            0           139m
aiops-lad-flink-taskmanager           0/0     0            0           139m
```

4. Shutdown the `Kafka` and `ZooKeeper` pods.

```
kubectl delete pod -l ibmevents.ibm.com/name=iaf-system-kafka -n aiops
kubectl delete pod -l ibmevents.ibm.com/name=iaf-system-zookeeper -n aiops
```

Run the following command to check that the Kafka and ZooKeeper pods have successfully shutdown. If the shutdown is complete, no pods are returned.

```
kubectl get pod -l ibmevents.ibm.com/controller=strimzipodset -n aiops
```

5. Scale down the PostgreSQL pods.

   When shutting down a PostgreSQL cluster, it is best to remove the primary replica last. The following script removes each database replica in the cluster with the primary removed last.

```
#!/bin/bash

AIOPS_NAMESPACE=aiops

# Get array of Postgres clusters
CLUSTERS=($(kubectl get clusters.postgresql.k8s.enterprisedb.io -n "${AIOPS_NAMESPACE}" -o go-template='{{range
.items}}{{.metadata.name}}{{" "}}{{end}}'))

# For each Postgres cluster, shutdown primary last
for cluster_name in "${CLUSTERS[@]}"; do
    primary=$(kubectl get clusters.postgresql.k8s.enterprisedb.io -n "${AIOPS_NAMESPACE}" "${cluster_name}" -o go-
template='{{.status.currentPrimary}}')
    instances=($(kubectl get clusters.postgresql.k8s.enterprisedb.io -n "${AIOPS_NAMESPACE}" "${cluster_name}" -o
go-template='{{range .status.instanceNames}}{{print . " "}}{{end}}'))
    for instance_name in "${instances[@]}"; do
        # Shutdown non-primary replicas
        if [ "${instance_name}" != "${primary}" ]; then
            kubectl delete pod -n "${AIOPS_NAMESPACE}" "${instance_name}" --ignore-not-found
        fi
    done

    # Shutdown the primary once all other replicas are down
    kubectl delete pod -n "${AIOPS_NAMESPACE}" "${primary}" --ignore-not-found
done
```

   Wait for all the Postgres pods to be deleted. All pods are deleted when the following command returns no pods:

```
kubectl get pod -l k8s.enterprisedb.io/podRole=instance -n aiops
```

6. (Optional) After the StatefulSets and StrimziPodSets are scaled down, drain all of the worker and control plane nodes. This step is not necessary if you are running a backup.

   From a control plane node, run the following command for each of the worker and control plane nodes:

```
kubectl drain <node>
```

   Where **<node>** is the name of the node to drain.

   Note: Some pods, such as storage pods, do not stop because this would violate the disruption budget. If this problem occurs, run the commands in each node until only the storage pods are left, and then stop the command and drain the next node.

5. Shut down the cluster

1. Shut down all the worker nodes on the cluster.
2. Shut down all the control plane nodes on the cluster.

6. Restart the cluster

1. Re-export the environment variables that you saved in step 1.1.
2. Restart the cluster nodes in the following order:
   1. Restart the control plane nodes. Check whether all the control plane nodes are in **ready** status by running the following command:

      ```
      kubectl get nodes
      ```

   2. Restart the worker nodes. Check whether all worker nodes are in **ready** status by running the following command:

      ```
      kubectl get nodes
      ```

3. After all the nodes are up, uncordon the control plane and worker nodes.

   From a control plane node, run the following command for each of the worker and control plane nodes:

```
kubectl uncordon <node>
```

   Where **<node>** is the name of the node to uncordon.

7. Scale up the workloads

Scaling up the workloads in the following order helps to minimize startup time and resource contention issues.

1. Scale the events operator back up.

```
kubectl scale deployment --replicas=1 $(kubectl get deployment -o custom-columns=NAME:.metadata.name --no-headers -n
aiops  | grep '^ibm-events-operator-') -n aiops
```

2. Check whether the Kafka and Zookeeper pods are running again. This can take a few minutes.

   ```
   kubectl get pod -l ibmevents.ibm.com/controller=strimzipodset -n aiops
   ```

   Example output when the Kafka and Zookeeper pods are running:

   ```
   NAME                                  READY   STATUS    RESTARTS   AGE
   iaf-system-kafka-0                    1/1     Running   0          13d
   iaf-system-kafka-1                    1/1     Running   0          13d
   iaf-system-kafka-2                    1/1     Running   0          13d
   iaf-system-zookeeper-0                1/1     Running   0          13d
   iaf-system-zookeeper-1                1/1     Running   0          13d
   iaf-system-zookeeper-2                1/1     Running   0          13d
   ```

3. You need to scale up each of the StatefulSets to the number of replicas as noted in step 3.2.

   1. Scale up Cassandra, Elasticsearch, and Spark StatefulSets in the following order:

      - aiops-topology-cassandra
      - aiops-ibm-elasticsearch-es-server-all
      - aiops-ir-analytics-spark-worker

      Run the following command to scale up each StatefulSet:

      ```
      kubectl scale statefulsets <statefulset> --replicas=<number of replicas> -n aiops
      ```

      Where:

      - **<statefulset>** is the StatefulSet to be scaled up
      - **<number_of_replicas>** is the number of replicas the StatefulSet it to be scaled up to

      For example,

      ```
      kubectl scale statefulsets aiops-topology-cassandra --replicas=1 -n aiops
      ```

   2. Scale the Flink deployments in the following order:

      - aiops-ir-lifecycle-flink
      - aiops-ir-lifecycle-flink-taskmanager
      - aiops-lad-flink
      - aiops-lad-flink-taskmanager

      Note: If you have a base deployment, then do not scale up **aiops-lad-flink** and **aiops-lad-flink-taskmanager**.

      Run the following command to scale up the Flink deployments:

      ```
      kubectl scale deployment <flink_deployment> --replicas=<number of replicas> -n aiops
      ```

      Where **<flink_deployment>** is the name of the Flink deployment.

   3. Scale the following StatefulSets in the specified order:

      - aiops-ir-core-ncoprimary
      - aiops-ir-core-ncobackup
      - c-example-couchdbcluster-m
      - aiops-installation-redis-server
      - aimanager-ibm-minio
      - zen-minio

      Run the following command to scale up each StatefulSet:

      ```
      kubectl scale statefulsets <statefulset> --replicas=<number of replicas> -n aiops
      ```

      Where:

      - **<statefulset>** is the StatefulSet to be scaled up
      - **<number_of_replicas>** is the number of replicas the StatefulSet it to be scaled up to

4. Scale up the operator deployments.

   ```
   kubectl scale deployment -l olm.owner.kind=ClusterServiceVersion -n aiops --replicas=1
   ```

8. Validate the installation

Note: After a complete cluster restart, it might take approximately an hour for the installation to start running again.

Run the describe command:

```
kubectl describe installations.orchestrator.aiops.ibm.com -n aiops
```

Review the **ComponentStatus** fields to confirm that all components are marked as **Ready** and the phase is **Running**.

Updating the deployment type (IBM Cloud Pak for AIOps on Linux)

Learn how to switch between the base deployment and extended deployment types.

Overview

After IBM Cloud Pak® for AIOps is installed, you can change your deployment type from a base deployment to an extended deployment, or from an extended deployment to a base deployment. For more information about the base deployment and extended deployment types, see Incremental adoption.

If you have log or ticket integrations configured that require an extended deployment, you are prevented from changing to a base deployment until these integrations are removed.

If you are changing from a base deployment to an extended deployment, the **aiopsctl** tool will check that your cluster meets the additional hardware requirements. For more information, see Hardware requirements.

Procedure

1. Set environment variables.
    1. Edit the **aiops_var.sh** file that you created when you installed IBM Cloud Pak for AIOps, and update the **DEPLOY_TYPE** environment variable to the required value.
    2. Run the following command from the directory that the script is in, to set the environment variables that are used later.

        ```
        . ./aiops_var.sh
        ```

    Note: If you do not still have **aiops_var.sh** from when you installed IBM Cloud Pak for AIOps, then follow the instructions for your deployment:

    Online deployment: Create environment variables or Offline deployment: Create environment variables.
2. Run the following command to update your deployment type.

    ```
    ssh ${TARGET_USER}@${CONTROL_PLANE_NODE} aiopsctl server up --load-balancer-host="${LOAD_BALANCER_HOST}" --mode "${DEPLOY_TYPE}"
    ```

Using a custom certificate (IBM Cloud Pak for AIOps on Linux)

Learn how to add a custom certificate to a deployment of IBM Cloud Pak® for AIOps on Linux®.

Procedure

If you want to use your own custom certificate for IBM Cloud Pak for AIOps instead of the default cluster certificate, then use the following steps after you have installed IBM Cloud Pak for AIOps on Linux.

1. Ensure that you have the following three PEM-encoded X.509 certificate files:
    - **caintermediate.pem**: The intermediate certificate that issued your server certificate.
    - **aiops.pem**: An IBM Cloud Pak for AIOps certificate, which includes the two fully qualified domain names (FQDNs) for **aiops-cpd** and **cp-console-aiops** in the Subject Alternative Name (SAN) list.
    - **aiops.key.pem**: A key file for the signed certificate in aiops.pem

    You can find the FQDNs for **aiops-cpd** and **cp-console-aiops** with the following command:

    ```
    kubectl get ingress -n aiops
    ```
2. Concatenate the server and intermediate certificates into one file called **aiops-certificate-chain.pem**.

    ```
    cat aiops.pem caintermediate.pem > aiops-certificate-chain.pem
    ```
3. Update the system configuration with the new certificate.

    ```
    aiopsctl server custom-certificate --certificate-file aiops-certificate-chain.pem --key-file aiops.key.pem
    ```

Installing and running the MustGather tool (IBM Cloud Pak for AIOps on Linux)

Learn about installing and running the MustGather tool for IBM Cloud Pak for AIOps on Linux.

Installing and running the MustGather tool

The MustGather tool is used for troubleshooting and support purposes. It collects data and logs about a deployment of IBM Cloud Pak for AIOps. To install and run the latest version of the MustGather tool, run the following command on the control plane node:

```
aiopsctl mustgather
```

Advanced configuration

You can also supply parameters to the MustGather tool. For more information, see Running the MustGather tool. In the example code blocks in the MustGather topics, replace **waiops-mustgather.sh** with **aiopsctl mustgather** for a deployment of IBM Cloud Pak for AIOps on Linux.

There are additional options available for deployments of IBM Cloud Pak for AIOps on Linux. Run the following command to seee usage:

```
aiopsctl mustgather -h
```

Example output:

```
root@acme-server:~# aiopsctl mustgather -h
Run the AIOps MustGather script to collect server information for support

Usage:
  aiopsctl mustgather [flags]

Flags:
  -a, --alias string      MustGather configuration alias
  -f, --force-install     Force MustGather to be reinstalled
  -h, --help              help for mustgather
  -o, --options string    Additional options that will be supplied to the MustGather script
  -u, --update            Check for MustGather updates

Global Flags:
      --accept-license     Accept the license
  -c, --config string      Config file location (default "~/.aiopsctl.yaml")
  -l, --log-file string    Log filename, set to stdout to print to console
      --show-secrets       Allow the display of secrets in output
  -v, --verbose            Verbose logging
      --wait-timeout int   Wait timeout for services to come ready in minutes (default 180)
```

Uninstalling IBM Cloud Pak for AIOps on Linux

Learn how to uninstall an online or offline (airgap) deployment of IBM Cloud Pak for AIOps on Linux, and to clean up the resources that it created.

Procedure

Use the following steps to uninstall IBM Cloud Pak for AIOps from your Linux cluster.

1. Export environment variables.

   Important: If you used an alternative path for APP_STORAGE_PATH when you set up your local application storage in Configuring local volumes, then you must change the value of this environment variable accordingly.

   ```
   export TARGET_USER="root"
   export CONTROL_PLANE_NODE="<control_plane_node_1>"
   export ADDITIONAL_CONTROL_PLANE_NODES=(
     "<control_plane_node_2>"
     "<control_plane_node_3>"
   )
   export WORKER_NODES=(
     "<worker_1>"
     "<worker_2>"
     "<worker_3>"
     "<worker_4>"
     "<worker_5>"
     "<worker_6>"
     "<worker_7>"
   )
   export APP_STORAGE_PATH="/var/lib/aiops/storage"
   ```

   Where:

   - `<control_plane_node_n>` is the FQDN or IP address of your control plane node. For example, "control-plane.example.com"
   - `<worker_n>` - is the FQDN or IP address of each worker node, where n is the number of nodes. For example, "worker-1.example.com"

2. Run the following commands from the control plane node:

   ```
   for WORKER_NODE in "${WORKER_NODES[@]}"
   do
     ssh ${TARGET_USER}@${WORKER_NODE} aiopsctl cluster node down --role worker --app-storage ${APP_STORAGE_PATH}
   done

   for CP_NODE in "${ADDITIONAL_CONTROL_PLANE_NODES[@]}"
   do
     ssh ${TARGET_USER}@${CP_NODE} aiopsctl cluster node down --role control-plane
   done

   aiopsctl cluster node down --role control-plane
   ```

Deploying IBM Cloud Pak for AIOps on OpenShift

You can install IBM Cloud Pak® for AIOps, Infrastructure Automation, or IBM Cloud Pak for AIOps and Infrastructure Automation on Red Hat® OpenShift® Container Platform. Online and offline deployments are supported.

If you need help deciding whether to install IBM Cloud Pak for AIOps on Red Hat OpenShift or Linux, see Choosing the deployment platform.

Notes:

- IBM Cloud Pak for AIOps and Infrastructure Automation can co-exist on the same cluster, but you cannot have multiple instances of either of them on the same cluster.
- You can optionally verify the IBM Cloud Pak for AIOps images before you install IBM Cloud Pak for AIOps. For more information, see Verifying images.
- After IBM Cloud Pak for AIOps is installed, you can optionally integrate with IBM Cognos® Analytics. For more information, see Visualizing dashboards and reports.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, you can optionally connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.

Read about planning an installation of IBM Cloud Pak for AIOps on Red Hat OpenShift, and then select one of the installation topics.

Planning an installation of IBM Cloud Pak for AIOps on OpenShift

Review the following information to help you plan your installation.

Incremental adoption

Learn about incremental adoption and the deployment types that are available. For more information, see Incremental adoption (IBM Cloud Pak for AIOps).

Supported platforms

Learn about the Red Hat® OpenShift® Container Platform versions and public clouds that you can deploy on. Supported platforms.

Hardware requirements

Review the memory and hardware requirements for your deployment. For more information, see Hardware requirements.

Storage requirements

Review the storage requirements for your deployment, and learn about supported storage providers and storage classes. For more infomation, see Storage requirements.

Network requirements

Review the list of ports that need to be exposed for use in inbound and outbound communication. For more information, see Network requirements

High availability

Review information about how to configure high availability (HA) for your deployment. For more information, see High availability (HA) considerations

Security considerations

IBM Cloud Pak for AIOps supports different mechanisms for securing your environment and your data. In addition, as you are planning or going through an installation of IBM Cloud Pak for AIOps, you might need to create or provide certificates. For more information, see Security considerations.

Licensing

As part of using IBM Cloud Pak for AIOps, tracking your license usage is required. Although IBM Cloud Pak for AIOps provides license options not tracked directly by the product, to track usage, you must deploy the IBM Cloud Pak foundational services License Service on all clusters where IBM Cloud Pak for AIOps is installed. This background service collects and stores the license usage information for tracking license consumption and for audit purposes. For more information, Licensing.

Incremental adoption (IBM Cloud Pak for AIOps on OpenShift)

Learn about incremental adoption and the deployment types that are available for IBM Cloud Pak® for AIOps.

Overview

incremental adoption offers the flexibility of two deployment types that provide a different combination of footprint and capabilities.

- **Base deployment**: has a smaller footprint than the extended deployment, with vCPU and memory savings of around 15% for a production deployment. The log anomaly detection and ticket analysis (similar incidents and change risk) capabilities are not enabled.
- **Extended deployment**: has a larger footprint and has the full capabilities of IBM Cloud Pak for AIOps enabled.

The IBM Cloud Pak for AIOps license entitles you to use either of the deployment types.

Capabilities and hardware requirements

Log anomaly detection collects and analyzes log data to identify deviations from expected patterns of behavior. For more information, see Log anomaly detection.

Ticket analysis collects ticket data and compares it with similar tickets previously associated with incidents to identify possible remediating changes, and the risk of implementing those changes. For more information, see Similar ticket comparison and Change risk.

For more information about the footprint of each deployment type, see Hardware requirements.

Selecting your deployment type (install)

You can choose to install a base deployment or an extended deployment of IBM Cloud Pak for AIOps. An editable value in the `Installation` custom resource, which is defaulted for a base deployment, determines the deployment type.

Deployments that upgrade to IBM Cloud Pak for AIOps 4.8.0 inherit their previous deployment type, which for deployments earlier than 4.8.0 is extended deployment.

For more information about setting the deployment type at installation time, see the topic for your installation method:

- Starter installation
- Online production installation (CLI method)
- Online production installation (console method)
- Installing in an air-gapped environment by using a bastion host
- Installing in an air-gapped environment by using a portable device

Changing your deployment type (postinstall)

Subject to further hardware requirements, you can update the deployment type of a new or upgraded deployment at any time after installation to be either a base deployment or an extended deployment. For more information, see Updating the deployment type.

Supported platforms

Learn about which Red Hat OpenShift Container Platform versions and public cloud platforms are supported for IBM Cloud Pak® for AIOps.

- Red Hat® OpenShift® Container Platform
  - IBM Fusion HCI Systems
- Linux®
- Cloud platforms
  - IBM Cloud®
  - AWS Marketplace
  - AWS GovCloud
  - Microsoft® Azure
  - Google Cloud Platform

Red Hat OpenShift Container Platform

IBM Cloud Pak for AIOps adheres to the IBM Cloud Pak and Red Hat OpenShift version compatibility objective, and support and recommend installing on a supported Red Hat OpenShift EUS minor version.

For more information about support timelines for Red Hat OpenShift, including when a specific version is going out of support, see the Red Hat OpenShift Container Platform Life-Cycle Policy in the Red Hat OpenShift documentation.

Table 1. Supported OpenShift versions

Deployment	Platform	Red Hat OpenShift Container Platform version
IBM Cloud Pak for AIOps	Linux x86_64	4.14 4.15 4.16 (minimum 4.16.4) 4.17

Important:

- If you are planning to upgrade Red Hat OpenShift as part of an upgrade to IBM Cloud Pak for AIOps 4.8.0, you must complete the IBM Cloud Pak for AIOps upgrade before you upgrade Red Hat OpenShift.

- The hardware architecture for installing IBM Cloud Pak for AIOps must be x86_64 (amd64).
- Red Hat OpenShift v4.14 and onwards support heterogeneous architectures, but IBM Cloud Pak for AIOps does not support heterogeneous architectures. All nodes in the Red Hat OpenShift cluster must have the same architecture.

Red Hat OpenShift installation mode

IBM Cloud Pak for AIOps supports the OpenShift **`OwnNamespace`** and **`AllNamespaces`** installation modes. The **`OwnNamespace`** installation mode is the recommended installation mode because it provides better resilience and performance.

In the **`OwnNamespace`** installation mode, you must create and select a project (namespace) for the IBM Cloud Pak for AIOps operator to be installed into. In this mode, the operator watches and is available for use only in this single namespace. The **`All namespaces on the cluster (default)`** installation mode in the UI installation of the IBM Cloud Pak for AIOps operator is equivalent to the **`AllNamespaces`** mode in the CLI installation. In this mode, the operator is installed in the **`openshift-operators`** project (namespace), and watches and is available to all namespaces in the cluster. The Operator Deployment Lifecycle Manager (ODLM) installs suboperators in the same project (namespace) that you created the **`Installation`** custom resource instance in. Each suboperator watches and is available for use in its project (namespace).

For more information on Red Hat OpenShift operator installation modes, see Operator groups in the Red Hat OpenShift Container Platform documentation.

Resource allocation for nodes

Red Hat OpenShift nodes must have adequate resources reserved. For more information, see Allocating resources for nodes in an OpenShift Container Platform cluster in the Red Hat OpenShift documentation, and the Red Hat Customer Portal.

IBM Fusion HCI Systems

IBM Fusion is a hyperconverged infrastructure configurated appliance to deploy bare metal Red Hat OpenShift on-premise along with IBM Fusion software. This is a simple turn-key enterprise-grade solution to deploy Red Hat OpenShift for consistent, rapid deployment and management.

You can install IBM Cloud Pak for AIOps on Red Hat OpenShift with IBM Fusion HCI Systems as your storage provider.

For more information, see IBM Fusion HCI Systems.

Linux

You can install a production deployment of IBM Cloud Pak for AIOps directly on Linux, without the need to install Red Hat OpenShift. For more information, see Deploying IBM Cloud Pak for AIOps on Linux.

Cloud platforms

IBM Cloud Pak for AIOps is supported on the following cloud platforms:

- IBM Cloud®
- AWS Marketplace
- AWS GovCloud
- Microsoft® Azure
- Google Cloud Platform

For more information about the storage providers that you can use on the following platforms, see Recommended storage providers.

IBM Cloud

You can install IBM Cloud Pak for AIOps on IBM Cloud® with:

- Red Hat OpenShift
- Red Hat® OpenShift® on IBM Cloud® service (ROKS). For more information about ROKS, see the Red Hat OpenShift documentation Red Hat OpenShift on IBM Cloud.

For more information about installing IBM Cloud Pak for AIOps on ROKS, see Installing IBM Cloud Pak for AIOps on ROKS.

AWS Marketplace

You can install IBM Cloud Pak for AIOps on AWS with:

- Red Hat® OpenShift®
- Red Hat OpenShift Service on AWS (ROSA). For more information about ROSA, see the Red Hat documentation Red Hat OpenShift Service on AWS.

For more information about installing IBM Cloud Pak for AIOps on ROSA, see Installing IBM Cloud Pak for AIOps on ROSA.

AWS GovCloud

You can install IBM Cloud Pak for AIOps on AWS GovCloud.

For more information about installing IBM Cloud Pak for AIOps on AWS into a government region, see Installing IBM Cloud Pak for AIOps on AWS GovCloud.

Microsoft® Azure

You can install IBM Cloud Pak for AIOps on Azure with:

- Red Hat OpenShift

- Azure Red Hat OpenShift (ARO). For more information about ARO, see the Microsoft documentation Azure Red Hat OpenShift.

  For more information about installing IBM Cloud Pak for AIOps on (ARO), see Installing IBM Cloud Pak for AIOps on ARO.

Google Cloud Platform (GCP)

You can install IBM Cloud Pak for AIOps on GCP with Red Hat OpenShift.

For more information about IBM Cloud Pak for AIOps on GCP, see Installing IBM Cloud Pak for AIOps on GCP.

Hardware requirements

Learn about the hardware requirements for a deployment of IBM Cloud Pak® for AIOps on Red Hat® OpenShift® Container Platform. Your hardware must be able to support Red Hat OpenShift, IBM Cloud Pak for AIOps, and your chosen storage solution.

Before you begin

- You cannot change your selected deployment size after installation.
- Multi-zone high availability disaster resolution (HADR) is available as a nonproduction technology preview.. For more information, see Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HADR).
- vCPU is defined as when one x86 CPU splits each of its physical cores into virtual cores (vCPU). It is assumed that one x86 CPU's physical core can be split into two logical vCPUs.
- If Red Hat OpenShift is installed on VMware virtual machines, set the value of the `sched.cpu.latencySensitivity` parameter to high.
- Persistent storage is also required, for more information, see Storage requirements.

You can deploy a starter, production, or custom sized deployment of IBM Cloud Pak for AIOps. The processing abilities and hardware requirements vary for each deployment size. Review the information in the following sections:

- Hardware requirements - Red Hat OpenShift
- Hardware requirements - IBM Cloud Pak for AIOps
- Integrations
- Requests and limits
- Processing abilities
- Custom sizing
- Infrastructure Automation

Hardware requirements - Red Hat OpenShift

A Red Hat OpenShift cluster has master nodes and worker nodes. Tables 1 and 2 show the minimum node requirements for Red Hat OpenShift to withstand the demands of starter and production deployments of IBM Cloud Pak for AIOps.

IBM Cloud Pak for AIOps requires your Red Hat OpenShift cluster to have at least three master nodes. IBM Cloud Pak for AIOps has many Kubernetes operators that interface with the `API server` and `etcd` storage, and so master nodes must be adequately sized.

The number of worker nodes that are required varies, and depends on the storage and processing requirements of your IBM Cloud Pak for AIOps deployment. The size of each of your worker nodes can vary, but the combined resources of your worker nodes must comply with the resource totals in Tables 3 and 4. Each worker node must meet the minimum requirements in Table 2 to accommodate the placement of larger IBM Cloud Pak for AIOps pods.

A higher recommended vCPU is also given in Table 2. When you are selecting the size of your worker nodes, you must balance cost considerations against the benefits of improved resiliency and the ease of scheduling workloads. Over-allocating resources can improve resiliency by enabling sufficient resources to be available if a worker node fails, and having well-sized worker nodes makes the placement of workloads easier. If your largest worker node becomes unavailable, resiliency is improved if your smallest worker node is able to handle the largest worker node's workloads. The degree of over-allocation of resources is correlated with the extent of failure scenarios that can be accommodated.

Table 1. Master node minimum requirements

Resource	Starter	Production
Master node count	3	3
vCPU per node	4	4
Memory per node (GB)	16	16
Disk per node (GB)	120	120

Table 2. Worker node minimum requirements

Resource	Starter	Production
Minimum vCPU per node	8	16
Recommended vCPU per node	16	16
Memory per node (GB)	12	20
Disk per node (GB)	120	120

Note: The numbers that are specified are minimums. For high production workloads, you might need a larger disk per node (GB) for your worker loads.

Hardware requirements - IBM Cloud Pak for AIOps

Table 3 and table 4 show the hardware requirements for starter and production deployments of IBM Cloud Pak for AIOps, for a base deployment and an extended deployment. For more information about the differences between a base deployment and an extended deployment, see Incremental adoption.

The resource requirements are given for the following scenarios:

- Table 3: IBM Cloud Pak for AIOps only - you are deploying IBM Cloud Pak for AIOps on an existing Red Hat OpenShift cluster.
- Table 4: IBM Cloud Pak for AIOps and Red Hat OpenShift - you are creating a new Red Hat OpenShift cluster and deploying IBM Cloud Pak for AIOps onto it.

Table 3. Minimum requirements for starter and production deployments, without Red Hat OpenShift

Resource	Base deployment IBM Cloud Pak for AIOps only (Starter)	Extended deployment IBM Cloud Pak for AIOps only (Starter)	Base deployment IBM Cloud Pak for AIOps only (Production)	Extended deployment IBM Cloud Pak for AIOps only (Production)
Master node count	•	•	•	•
Minimum worker node count	3	3	6	6
Total vCPU	47	55	136	162
Total memory (GB)	123	136	310	368

Table 4. Minimum requirements for starter and production deployments, with Red Hat OpenShift

Resource	Base deployment IBM Cloud Pak for AIOps and Red Hat OpenShift (Starter)	Extended deployment IBM Cloud Pak for AIOps and Red Hat OpenShift (Starter)	Base deployment IBM Cloud Pak for AIOps and Red Hat OpenShift (Production)	Extended deployment IBM Cloud Pak for AIOps and Red Hat OpenShift (Production)
Master node count	3	3	3	3
Minimum worker node count	3	3	6	6
Total vCPU	59	67	148	174
Total memory (GB)	171	184	358	416

The Red Hat OpenShift master and worker nodes must meet the minimum size requirements in Hardware requirements - Red Hat OpenShift only.

Note:

- These values do not include CPU and memory resources for hosting a storage provider, such as Red Hat® OpenShift® Data Foundation or Portworx. Storage providers can require more nodes, more resources, or both, to run. The extra resources that are needed can vary based on your selected storage provider. A general recommendation is for one extra worker node for a starter deployment, and for three extra worker nodes for a production deployment. Consult your storage provider's documentation for exact requirements.
- An additional 1 vCPU and 3GB memory is required for each integration that you configure. For example, if you configure two Netcool integrations then you will require an additional 2 vCPUs and 6GB memory.

Warning: Insufficient hardware will result in product instability and loss of function. Verify that your hardware is sufficiently sized for your expected workloads. For more information, see Processing abilities. In addition to the default starter and production size deployments, you can choose to deploy a custom-sized deployment of IBM Cloud Pak for AIOps. For more information, see Custom sizing.

Integrations

When you are configuring an integration in IBM Cloud Pak for AIOps, it is important to consider the performance and footprint. If you have large amounts of data on the selected target system, you can expect relatively higher resource usage from collecting data from that system when compared to a system with less data. Additionally, the sizing of the IBM Cloud Pak for AIOps installation affects the number of resources that are available for running integrations. Review the following considerations for each integration category and the **integration installation** section before you configure a new integration.

Integration installation

IBM Cloud Pak for AIOps integrations for metrics, events, and logs are configured in the Integrations UI page, which can be used to create, edit, delete, and track the status of integrations. Integrations run as pods and have minimum and maximum resource allocations in terms of CPU, memory and storage. Some integrations offer flexibility in terms of how to install the integration in the UI, but some integrations only offer one option.

You can use the following two options to install integrations:

- **Local**: Install the integration in the same cluster and namespace where IBM Cloud Pak for AIOps is installed. The integration's status is displayed in the Integrations UI page and is automatically managed by IBM Cloud Pak for AIOps.
- **Remote**: Install the integration anywhere you choose, for example, a different network region, on SaaS, or remote on-premises (VM, cluster or container). After adding the integration, you can use the script to run the integration pod using podman.

Regardless of whether an integration is a local or remote installation, the data collected by IBM Cloud Pak for AIOps is stored for some time in Kafka.

Note: Before you set up your first integration, make sure that Kafka storage is correctly configured and scaled for the production environment. If the Kafka persistent volume claims (PVCs) is near capacity, increase each of the PVCs by an extra 60 GB. For more information, see Increasing Kafka PVC.

Hardware requirements - Integrations

Before you create an integration for both local and remote installation, make sure that IBM Cloud Pak for AIOps or remote environment contains the hardware resources that are required to run the integrations.

The minimum resource requirements for the integrations are listed in the following table:

Table 1. Minimum requirements for integrations

Integration name	Memory limit (Mb)	CPU limit	Ephemeral storage limit (Mb)

Integration name	Memory limit (Mb)	CPU limit	Ephemeral storage limit (Mb)
AppDynamics New Relic Splunk	2500	1	500
AWS CloudWatch, Dynatrace (metrics-only), Infrastructure Management, Generic Webhook, Zabbix	4096	1	500
Dynatrace (metrics, events, topology)	10000	4	8000
DB2, GitHub, ServiceNow	800	1	1000
Email Notifications, IMPACT, Jira	512	1	1000
Instana	4096	4	1000
Netcool ObjectServer	4096	2	2000
Custom, Elk, Falcon LogScale, Mezmo	1536	1	1000

Notes:

- Dynatrace (metrics, events, topology) supports up to 5 integrations.
- The hardware sizing in the preceding table does not include resource slots for logs integrations or observer jobs. For more information about resource slots for logs integrations, see Performance considerations for logs data collection. For more information about defining observer jobs, see Observer jobs.

For performance considerations for integrations, see the following sections:

- Performance considerations for metrics data collection
- Performance considerations for logs data collection
- Performance considerations for events data collection
- Performance considerations for tickets data collection
- Performance considerations for observers

Requests and limits

In Kubernetes, requests define the resources that must be provided, and limits define the upper boundary of extra resources that can be allocated. Resource quotas can optionally be used to dictate the allowed totals for all requests and limits in a namespace. If a resource quota is set, then it must be at an adequate level to ensure that workload placement is not inhibited. If you do not deploy resource quotas, then skip this section.

The following table shows the requests and limits that the IBM Cloud Pak for AIOps installation namespace require for a typical starter or production deployment.

Table 5. Requests and limits requirements for the IBM Cloud Pak for AIOps installation namespace

Resource name	IBM Cloud Pak for AIOps installation namespace (Starter)	IBM Cloud Pak for AIOps installation namespace (Production)
CPU Request	75	227
Memory Request (Gi)	195	466
Ephemeral Storage Request (Gi)	105	200
CPU Limit	210	436
Memory Limit (Gi)	260	533
Ephemeral Storage Limit (Gi)	340	600

Important: Deployment of additional services impacts these values. Review these values regularly to ensure that they still meet your requirements. Extra resources are required for upgrade, for more information see Ensure cluster readiness.

Use the Red Hat OpenShift command line to create or edit a **`ResourceQuota`** object with these values. For more information, see Quotas in the Red Hat OpenShift documentation.

The following example YAML file show the YAML to create **`ResourceQuota`** objects for the IBM Cloud Pak for AIOps installation namespace in a production deployment of IBM Cloud Pak for AIOps:

```
apiVersion: v1
kind: ResourceQuota
metadata:
  name: aiops-large
  namespace: cp4aiops
spec:
  hard:
    requests.cpu: "227"
    requests.memory: 466Gi
    requests.ephemeral-storage: 200Gi
    limits.cpu: "436"
    limits.memory: 533Gi
    limits.ephemeral-storage: 600Gi
    pods: '275'
```

Processing abilities

Expand the following sections to find out about the processing abilities of starter and production sized deployments of IBM Cloud Pak for AIOps. Higher rates are supported by custom sizes. For more information about customizing the size of your IBM Cloud Pak for AIOps deployment according to your processing and footprint requirements, see Custom sizing.

Supported resource number and throughput rates for starter and production deployments

▶ Expand this section for details.

Event, alert, and incident rates

▶ Expand this section for details.

Custom sizing

The default starter and production deployment sizes enable the full capabilities of IBM Cloud Pak for AIOps to be used with the workload volumes that are stated in the Processing abilities section. If different workload volumes are required or resource constraints are an issue, then specific capabilities such as **`Metric Anomaly Detection`**, **`Log Anomaly Detection`**, and **`Runbook Automation`** can be sized accordingly. IBM Sales representatives and Business Partners have access to a custom sizing tool that can assess your runtime requirements and provide a custom profile that scales IBM Cloud Pak for AIOps components. The custom profile is applied when you install IBM Cloud Pak for AIOps. This custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. If you require custom sizing, contact IBM Sales representatives and Business Partners with details of your intended workloads.

Table 7 shows the processing abilities of some custom-sized deployments of IBM Cloud Pak for AIOps.

Example 1 (Minimum scale) represents a minimally sized deployment of IBM Cloud Pak for AIOps for the evaluation of event management. It demonstrates event analytics, noise reduction, and the automation of issue resolution on a small topology. Metric and log anomaly detection and change risk assessment are de-emphasized. Example 1 requires 49 vCPU and 143 GB memory.

Example 2 (Event management focused) represents a production deployment of IBM Cloud Pak for AIOps which is focused on event management capabilities. It supports event analytics, noise reduction, and the automation of issue resolution on a large topology. Metric and log anomaly detection and change risk assessment are de-emphasized. Example 2 requires 176 vCPU and 366 GB memory.

Maximum scale shows the upper limits that IBM Cloud Pak for AIOps can be scaled to, across all of its capabilities.

Table 7. Processing abilities of example custom-sized deployments

Component	Resource	Example 1	Example 2	Maximum scale
Change risk	Incidents and change request records per second	0	0	N/A
Metric anomaly detection	Maximum throughput - (KPIs) for all metric integration	0	0	5,000,000
Log anomaly detection	Maximum throughput (log messages per second) for all log integrations	0	0	25,000
Events (through Netcool integration)	Steady state event rate throughput per second Burst rate event throughput per second	10	600	700 1000
Automation runbooks	Fully automated runbooks run per second	1	2	4
Topology management	Maximum number of topology resources	5,000	5,000,000	15,000,000
UI users	Active users supported	5	40	40

Infrastructure Automation

For more information about the hardware requirements for your Infrastructure Automation deployment on Red Hat® OpenShift® Container Platform, see Hardware requirements.

Performance considerations for metrics data collection

When you configure an integration in IBM Cloud Pak® for AIOps that collects metrics data, such as AppDynamics, AWS CloudWatch, Dynatrace, Instana, New Relic, Splunk, or Zabbix, it is important to consider the amount of data on the target system when you select the metrics.

If you have large amounts of data on a selected target system, for example thousands of hosts, you can expect higher resource usage when you collect data from that system as compared to a system with less data. For target systems with many hosts, consider the following actions to help ensure that your integration works as expected:

- Do not select all the metrics. Instead, review the documentation for the target system that you are pulling data for, understand the metrics and select the metrics that are useful. All metrics are not suited for all the use cases. Select a small, meaningful set of metrics, and expand the selected metrics when you confirm the initial use case.
- Do not select all the hosts for an integration. Some metrics integrations offer the ability to filter by specific hosts or you can define a filter to narrow down the metric data pulled for specific hosts.
- Use filters when possible to reduce the risk of exceeding the limitations of the API or the integration. The filters that are available for each integration are documented in the topic for each integration.
- Each integration needs a unique API token. Each API token has its own requests limit. If integrations share API tokens, then they are at a risk of exceeding the request limits.
- When you configure some integrations in the UI, you can reduce the length of time for historical data collection or reduce the base parallelism to decrease the resource usage of the integration. If multiple metrics are selected, consider collecting data for a time that is less then two weeks.
- Do not create more than 10 metrics integrations on a small cluster or 20 integrations on a large cluster at one time. If multiple integrations are running simultaneously, then more KPIs are sent to Cloud Pak for AIOps. The number of KPIs collected by the metrics integrations must not exceed the limitations for metric anomaly detection. For more information, see Custom sizing.

The following table lists the filters that are available for metric integrations:

Table. Available filters for metric integrations

Metric integration name	Metrics filtering	Host filtering	Namespace filtering	Application filtering	Technology filtering	Index filtering	Management zone	Tags
AppDynamics	Yes	No	No	Yes	No	No	No	No
AWS CloudWatch	Yes	No	Yes	No	No	No	No	No
Dynatrace (metrics-only)	Yes	No	No	No	Yes	No	No	Yes
Dynatrace (metrics, events, topology)	Yes	No	No	No	Yes	No	Yes	Yes
Instana	Yes	No	No	No	Yes	No	No	No
New Relic	Yes	No	No	Yes	No	No	No	No
Splunk	Yes	Yes	No	No	No	Yes	No	No
Zabbix	Yes	Yes	No	No	Yes	No	No	No

Performance considerations for logs data collection

When you configure an integration in IBM Cloud Pak® for AIOps that collects logs data, such as Custom, Elk, Falcon LogScale, Kafka, Mezmo, and Splunk Enterprise, it is important to consider the resource requirements for creating a new integration.

Consider the following actions to help ensure that your integration works as expected:

- Use filters when possible to reduce the risk of exceeding the limitations of the API or integration. The filters available for each integration are documented in the topic for each integration.
- Each integration needs a unique API token. Each API token has its own requests limit. If integrations share API tokens, then they are at a risk of exceeding the request limits.
- Monitor the of the number of logs integrations that are created and the size of the Cloud Pak for AIOps installation. The amount of logs data collected per interval must not exceed the limitations of log anomaly detection. For more information, see Custom sizing.

Cloud Pak for AIOps applies various analytics and transformations to the stream of log data. For scaling to high-volume workloads, the data stream is parallelized using the concept of slots. Each slots consists of a given unit of CPU and memory. Each integration requires one or more slots dependencing on the base parallelism setting, data collection setting, and the data volume. Additional slots are required to support high availability (failover) scenarios, which are available only on large installations of Cloud Pak for AIOps.

When creating a new integration, make sure that there are enough slots on Cloud Pak for AIOps to support the logs integration.

Performance considerations for events data collection

Learn more about the performance considerations for Generic Webhook and Kafka integrations in IBM Cloud Pak® for AIOps.

Generic Webhook integration

When you configure the Generic Webhook integration, it is important to consider the maximum event rate (per second) when you create an integration.

The Generic Webhook integration provides the option to configure a maximum event rate, which can have a minimum of 10 and a maximum of 1000 events per second with a default value of 100. To avoid the rejection of events, scale the maximum event rate if you anticipate exceeding the maximum events rate limit for the integration.

Kafka integration

When you are configuring the Kafka integration, it is important to consider the following performance factors:

- The Kafka replication factor is set to one replica by default. If you are implementing a production deployment of Cloud Pak for AIOps, you might lose data if your Kafka pods fail or restart. If the data collection is enabled in your Kafka integration when the Kafka pods go down, you might experience a gap in the data that your integration generated during the downtime.
- The maximum Kafka message size limit in Cloud Pak for AIOps is 1048588 bytes. If you frequently send in messages that are close to the maximum size, it can adversely impact the performance of the integration. If the maximum message size limit is exceeded, the message is rejected.

Performance considerations for tickets data collection

Learn more about the performance considerations for Jira, GitHub and ServiceNow integrations in IBM Cloud Pak® for AIOps.

When you configure ticketing integrations in Cloud Pak for AIOps, it is important to consider the following performance factors:

- Use filters when possible to reduce the risk of exceeding the limitations of the API or integration. The filters available for each integration are documented in the topic for each integration.
- Each integration needs a unique API token. Each API token has its own requests limit. If integrations share API tokens, then they are at a risk of exceeding the request limits.
- If the GitHub or Jira integrations exceed API rate limits from the target system, there might be a delay in data collection. The GitHub or Jira integrations implement a pause and wait strategy until the API rate limit is refreshed before making additional requests.
- If available in the UI for the integration that you are configuring, you can adjust the data collection interval to reduce the resource usage of the integration.

Performance considerations for observers

When you configure observer integrations in IBM Cloud Pak® for AIOps, then use the following considerations:

- Observer filtering capabilities need to be used where possible to help fine-tune what the integration provides to Cloud Pak for AIOps. This approach ensures that Cloud Pak for AIOps focuses on managing only what is necessary to deliver value, while maximizing efficiency in both data source and data processing.
- Observer data is sent to a Kafka topic for processing by the topology-service microservice, but the processing rate is significantly lower than the production rate, causing data to accumulate in the Kafka topic. If large observer jobs are run in parallel, processing might exceed Kafka's 8-hour default message retention time, leading to data loss, discarded control plane messages, and stuck jobs. To mitigate these risks, it is recommended to run large observer jobs sequentially and moderate the number of jobs that run in parallel.
- Merge, group processing and populating the inventory database can continue after a given observer job is marked as finished, which indicates that the topology microservice has consumed and processed the data.
- If you are using the File observer, files should be constrained to 1m resources to keep the quantity of tracked metadata and processing times manageable.
- Observer load jobs automate the process of determining the differences between subsequent loads of the same data. The system simplifies the authoring of a data source by automatically handling changes between loads, such as resources A,B,C being provided at time 1 and resources A,C,D being provided at time 2. The observer downloads the set of identifiers for the previous run from the topology service REST APIs at job start-up and compares the IDs for time 1 and 2. The system automatically deletes any IDs that are not found in time 2, eliminating the need for a linger concept. The system resurrects resource B if it reappears at time 3.
- If you are using the File or REST observers (or writing a new one), then consider the resource properties that are required to meet business goals. It is not useful to provide large number of properties if a better experience and more up-to-date data can be obtained through federation to the source by using a right-click contextual tool launch. Otherwise, every property needs to be stored and managed, which can slow the processing down. In extreme cases, Kafka might discard the message from the observer as the maximum message size is 1.5 Mb.
- If you are using the File or REST observers (or writing a new one), consider the number of edges (relationships) that each resource contains to avoid the supernodes. A supernode in a topology graph is a node with disproportionately high number of relationships. It is recommended to exercise caution when you are exceeding 400 relationships incident to a given resource. The reason is that the user experience can suffer. In extreme cases, such as thousands of relationships, Kafka might discard the message from the observer as the maximum message size of Kafka is 1.5 Mb. Relationships in topology manager can accumulate across individual contributions to a resource by using merge processing.
- If you are using the File or REST observers (or writing a new one), consider the order in which data is provided to the Topology Manager. For example, the order of lines in a file or the sequence in which the **`applyVertex`** method is executed in a COTS observer. Topology Manager contains the logic to handle out-of-sequence data and reassemble it, but this can consume the memory and reduce performance. Consider the case where resource A is related to resources B, C, and D. If A is sent first with relationships to B, C and D as part of it, then placeholders need to be tracked for B, C, and D until the full records arrive. In extreme cases, tens or hundreds of thousands of records might be generated after A is first seen. To minimize placeholder tracking, it is recommended to send B, C, and D before A, if possible. Alternatively, relate B, C, and D to A by using a relationship from/to each of those for A. To increase the likelihood that the resources that are referenced without relationships are previously sent to the topology service, you can generate a sorted list of resources in Python by using the following code:

  ```
  for resource in sorted(topology, key=lambda k: (len(topology[k]['_references']), topology[k]['uniqueId'])):
  ```

  This code sorts the resources by the number of relationships and unique ID, ensuring that resources with fewer relationships are sent first.
- When providing data to the topology service, you choose the operation to perform such as, **`insert-replace`**, **`insert-update`**, or **`delete`**. The topology service performs the chosen operation. **`Insert-replace`** is the simplest and most reliable method, as it does not require advanced user knowledge to use correctly. Incorrect use of **`insert-update`** might result in a topology with decreasing accuracy over time.
- Observers can provide groups to Topology Manager automatically. Consider the meaning of group to the business, the number of groups created and the number of resources within each group. Groups over 2,000 resources can result in a poor user experience. Defining groups by using templates is recommended, as it provides greater administrative control over the creation of groups, including how, when, and why they are created. If a group must be created by using an observer directly, then provide an option to suppress or filter the groups that it creates.

Storage requirements

Learn about the storage requirements for IBM Cloud Pak® for AIOps.

- Persistent storage requirements
- Persistent storage sizing
- Recommended storage providers

Persistent storage requirements

IBM Cloud Pak for AIOps requires persistent storage that supports the RWO (read-write-once) access mode. Use of the Red Hat OpenShift APIs for Data Protection (OADP) backup and restore method requires persistent storage that supports the RWX (read-write-many) access mode. For more information about the backup and restore methods available for IBM Cloud Pak for AIOps, see Back up and restore (IBM Cloud Pak for AIOps on OpenShift).

Important: The file system used by MinIO must be `XFS`, not `ext4`. The `ext4` file system has a limit on the number of inodes that can be created for each file system. If inode usage reaches 100%, the file system becomes read-only even if enough PVC space is available and MinIO is prevented from creating new files or directories. Refer to your storage provider's documentation for information about setting `XFS` as the file system.

Storage class requirements

For production environments, storage classes must have `allowVolumeExpansion` enabled. This allows persistent volumes to be expanded if necessary, to avoid storage from filling up and causing unrecoverable failures. This is also highly recommended for starter deployments, since without it you are limited to the default capacity that might not be sufficient for your specific needs. To enable `allowVolumeExpansion`, edit the storage class to enable expansion. Follow the instructions in the Red Hat documentation Enabling volume expansion support.

IOPS requirements

Table 1 identifies the input/output operations per second (IOPS) per node that must be supported for a 3-node storage solution. Ensure that your hardware can support the expected IOPS per node. A minimum configuration of three nodes for the storage cluster is needed. Each node of the storage solution requires a minimum of one disk (SSD or high-performance storage array).

Table 1. IOPS requirements

Deployment size	Minimum	Recommended
Starter deployment	2,000	5,000
Production deployment	10,000	20,000

The results for your storage can vary depending on your exact usage, data sets, hardware, storage solution, and more. The preceding IOPS minimum and recommended values are based on a Red Hat® OpenShift® Data Foundation storage solution.

Persistent storage sizing

Red Hat OpenShift uses the Kubernetes persistent volume (PV) framework. PVs are storage resources in the cluster, and persistent volume claims (PVCs) are storage requests that are made on those PVs by IBM Cloud Pak for AIOps. For more information about persistent storage in Red Hat OpenShift clusters, see Persistent storage overview.

A starter deployment requires 463 Gi of persistent storage, and a production deployment requires 1928 Gi of persistent storage.

Table 2. Persistent storage sizing

Component	Starter deployment PVC size (Gi) Total (number of PVCs x PVC size)	Production deployment PVC size (Gi) Total (number of PVCs x PVC size)	Access mode	Storage mode
Cassandra (data and backup)	100 (2x50)	300 (6x50)	RW0	Block
Common service db	20 (2x10)	40 (4x10)	RWO	Block
Topology file observer	5 (1x5)	5 (1x5)	RWO	Filesystem
CouchDB	20 (1x20)	60 (3x20)	RWO	Filesystem
Elasticsearch	100 (1x100)	300 (3 x 100)	RWO	Block
Kafka	60 (1x60)	300 (3x100)	RWO	Block
Zookeeper	10 (1x10)	30 (3x10)	RWO	Block
Redis	3 (3x1)	3 (3x1)	RWO	Block
AIOps MinIO	50 (1x50)	500 (5X100)	RWO	Block
Zen MinIO	30 (3x10)	30 (3x10)	RWO	Block
EDB Postgres	15 (1x15)	300 (3x100)	RWO	Block
CS Postgres backup	10 (1x20)	20 (1x20)	RWO	Block
Zen Objectstore backup	20 (1x20)	20 (1x20)	RWO	Block
Zen Metastoredb EDB	20 (2x10)	20 (2x10)	RWO	Block
Total	463	1928		

The preceding table provides PVC sizings that provide adequate space to begin working with IBM Cloud Pak for AIOps, but you may need to increase these values later. For more information, see Resizing storage.

Notes:

- The access mode is ReadWriteOnce (RWO) for each PV. Usage of OADP backup and restore requires ReadWriteMany (RWX) access mode. For more information about access modes, see Access modes.
- Depending on the size of the training sets, usage, and data retention needs, your deployment can require additional storage.
- The storage type is shown for each of the PVs, and is either Filesystem or Block. For more information about persistent storage, see the Red Hat documentation about Persistent storage overview.

Additional storage requirements for offline (airgap) deployments

If you are installing in an air-gapped environment (offline), you must ensure that the target registry and any intermediary portable devices have adequate space to download the IBM Cloud Pak for AIOps images. The IBM Cloud Pak for AIOps images total 140 GB.

If you are also going to install IBM Cognos® Analytics, then you will require an additional 155 GB.

Additional storage requirements for backup and restore

The backup and restore of IBM Cloud Pak for AIOps is based on the storage and database backup of critical data stores, cluster resources, and component data and settings, such as issue resolution policy settings, Runbooks, automated actions, metric data, log anomaly models, related secrets and configmaps, and more. With the backup and restore feature, you can recover your services to a previous point in time backup to recover from data corruption, system failures, or user errors.

To support backing up your IBM Cloud Pak for AIOps environment, you need to provision storage specifically for storing and retrieving backups. This storage also needs to be accessible by any environment where a backup might need to be restored. The backup process for IBM Cloud Pak for AIOps requires S3 compliant object stores for storing and retrieving backups. For instance, you can use the following public or private cloud options for provisioning this storage:

- MinIO
- Red Hat OpenShift Data Foundation object store
- IBM Cloud Object Storage
- AWS Cloud

Tip: As your data grows, the size of your backup storage might need to grow. Ensure that sufficient storage is provisioned to accommodate any expected growth in data size. For more information about the backup and restore process, see Backing up and restoring IBM Cloud Pak for AIOps.

Recommended storage providers

The recommended storage providers are:

- IBM Cloud
- Red Hat OpenShift Data Foundation (ODF)
- IBM Fusion Data Foundation
- IBM Fusion Global Data Platform
- IBM Storage Scale Container Native
- Portworx
- AWS native storage

The following table shows the tested and supported storage providers for the platforms that IBM Cloud Pak for AIOps can be deployed on.

Table 2. Supported storage providers by platform

Platform	IBM Cloud Storage (Block and File)	Red Hat® OpenShift® Data Foundation	IBM Fusion Data Foundation	IBM Fusion Global Data Platform	IBM Storage Scale Container Native	Portworx	AWS native storage
Azure Red Hat OpenShift (ARO)		Yes				Yes	
Google Cloud Platform (GCP)		Yes				Yes	
Red Hat OpenShift Container Platform		Yes	Yes	Yes	Yes	Yes	Yes
Red Hat OpenShift on IBM Cloud (ROKS)	Yes	Yes	Yes	Yes	Yes		
AWS GovCloud						Yes	
Red Hat OpenShift Service on AWS (ROSA)						Yes	Yes

Notes:

- IBM Storage Scale Container Native and Red Hat® OpenShift® Data Foundation are part of IBM Storage Suite for IBM Cloud Paks.
- IBM Cloud Pak for AIOps requires persistent RWX (read-write-many) storage for OADP backup and restore. Red Hat® does not currently support Red Hat® OpenShift® Data Foundation (ODF) on ROSA. Portworx is the only recommended storage provider that provides a RWX storage solution for a deployment of IBM Cloud Pak for AIOps on ROSA. Portworx is available for a free 30 day trial, but will require a license for a longer timespan and production usage.

The preceding storage providers are the only providers that are tested and validated for a deployment of IBM Cloud Pak for AIOps. You can choose to use an alternate storage provider if they meet the requirements for deploying IBM Cloud Pak for AIOps. Your chosen storage provider must meet the same storage and hardware requirements as the recommended storage providers. For instance, for deploying IBM Cloud Pak for AIOps, your chosen provider must support the required access modes and storage modes. If you choose to use an alternate storage provider, your overall performance can differ from any listed sizings, throughput rates or other performance metrics that are listed in the IBM Cloud Pak for AIOps documentation. Work with your IBM Sales representative (or Business Partner) to ensure that your chosen storage provider is sufficient for your deployment plan.

IBM Cloud

The following storage classes are required by IBM Cloud Pak for AIOps, and are created when Red Hat OpenShift on IBM Cloud (ROKS) is installed:

Storage provider	Storage class name	Large block storage class name
IBM Cloud® (without OADP backup and restore)	ibmc-block-gold	ibmc-block-gold
IBM Cloud® (with OADP backup and restore)	ibmc-file-gold-gid	ibmc-block-gold

Installing IBM Cloud storage

For more information about IBM Cloud storage, see Storing data on classic IBM Cloud File Storage and Storing data on classic IBM Cloud Block Storage in the IBM Cloud Docs.

Red Hat OpenShift Data Foundation (ODF)

The following storage classes are required by IBM Cloud Pak for AIOps, and are created when Red Hat OpenShift Data Foundation is installed:

Storage provider	Storage class name	Large block storage class name
Red Hat® OpenShift® Data Foundation (without OADP backup and restore)	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
Red Hat® OpenShift® Data Foundation (with OADP backup and restore)	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd

Installing Red Hat OpenShift Data Foundation

Red Hat OpenShift Data Foundation is available for purchase through the IBM Storage Suite for IBM Cloud Paks. Red Hat OpenShift Data Foundation is an implementation of the open source Ceph storage software, which is engineered to provide data and storage services on Red Hat OpenShift. Use version 4.12 or higher.

For more information about deploying Red Hat OpenShift Data Foundation, see Deploying OpenShift Data Foundation in the Red Hat documentation. Choose the appropriate deployment instructions for your deployment platform.

Important: Red Hat OpenShift Data Foundation provide additional configuration steps, which can alleviate potential problems with delayed space reclamation. For more information, see Reclaiming space on target volumes in the Red Hat OpenShift Data Foundation documentation.

These additional configuration steps are not specific to IBM Cloud Pak for AIOps, and are required for any application that experiences a high volume of writes that are then deleted. For IBM Cloud Pak for AIOps, this might be an event storm where large numbers of events are ingested and resolved, or when a large quantity of short-term metric data is ingested and then deleted. Failure to properly configure storage can cause out of disk space errors that might not be readily apparent. In some scenarios, you might need to contact your storage provider to ensure proper storage configuration for your needs.

IBM Fusion Data Foundation

The following storage classes are required by IBM Cloud Pak for AIOps:

Storage provider	Storage class name	Large block storage class name
IBM Fusion Data Foundation (without OADP backup and restore)	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation (with OADP backup and restore)	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd

Installing IBM Fusion Data Foundation

IBM Fusion Software version 2.9.0 and IBM Fusion HCI Systems version 2.9.x are compatible with IBM Cloud Pak for AIOps.

To learn more about IBM Fusion and how to install IBM Fusion Data Foundation service, see the following two methods:

IBM Fusion Software

IBM Fusion Data Foundation is a highly integrated collection of cloud storage and data services for Red Hat OpenShift Container Platform. It is available as part of the Red Hat OpenShift Container Platform service catalog, packaged as an operator to facilitate simple deployment and management.

The IBM Fusion Software provides the following features:

- IBM Fusion software is a software-only solution that can be deployed on a variety of hardware platforms.
- IBM Fusion software is designed to scale up to meet the needs of larger environments.
- IBM Fusion software can be integrated with a variety of third-party solutions.

Before you install IBM Fusion, ensure that you meet all of the prerequisites. For more information, see Prerequisites.

For more information about Deploying IBM Fusion, see Deploying IBM Fusion.

For more information about how to install Data Foundation service using IBM Fusion, see Data Foundation.

For more information about IBM Fusion Software storage class, see Data Foundation.

IBM Fusion HCI Systems

The IBM Fusion Data Foundation service provides a foundational data layer for applications to function and interact with data in a simplified, consistent, and scalable manner.

The IBM Fusion HCI Systems provides the following features:

- IBM Fusion HCI system is a pre-integrated, pre-tested, and pre-configured appliance that combines hardware and software.
- IBM Fusion HCI system is designed to scale out to meet growing storage needs.
- IBM Fusion HCI system is tightly integrated with IBM's other hybrid cloud solutions, such as IBM Cloud and IBM Power Systems.

For more information about Prerequisites of IBM Fusion HCI system, see Planning and prerequisites.

For more information about Deploying IBM Fusion HCI System, see Deploying IBM Fusion HCI System.

For more information about how to install Data Foundation service using IBM Fusion HCI Systems, see Data Foundation.

For more information about IBM Fusion HCI Systems storage class, see Data Foundation.

IBM Fusion Global Data Platform

The following storage classes are required by IBM Cloud Pak for AIOps:

Storage provider	Storage class name	Large block storage class name
IBM Fusion Global Data Platform: IBM Fusion	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc
IBM Fusion Global Data Platform: IBM Fusion HCI System	ibm-storage-fusion-cp-sc	ibm-storage-fusion-cp-sc

Installing IBM Fusion Global Data Platform

The Global Data Platform storage type provides the following features:

- File storage
- High availability via capacity-efficient erasure coding
- Metro and regional disaster recovery
- CSI snapshot support with built-in application consistency
- Encryption at rest
- Ability to mount file systems hosted by remote IBM Storage Scale clusters.

Important: IBM Fusion Global Data Platform provide additional configuration steps, which can alleviate potential problems with delayed space reclamation. For more information, see Enabling reclaim space operation using Annotating PersistentVolumeClaims in the IBM Fusion documentation.

These additional configuration steps are not specific to IBM Cloud Pak for AIOps, and are required for any application that experiences a high volume of writes that are then deleted. For IBM Cloud Pak for AIOps, this might be an event storm where large numbers of events are ingested and resolved, or when a large quantity of short-term metric data is ingested and then deleted. Failure to properly configure storage can cause out of disk space errors that might not be readily apparent. In some scenarios, you might need to contact your storage provider to ensure proper storage configuration for your needs.

You can deploy Global Data Platform service by using the following two methods:

IBM Fusion Software

Before you install IBM Fusion, ensure that you meet all of the prerequisites. For more information, see Prerequisites.

For more information about Deploying IBM Fusion, see Deploying IBM Fusion.

For more information about how to install Global Data Platform using IBM Fusion Software, see Global Data Platform.

For more information about IBM Fusion Software storage class, see IBM Storage Scale.

IBM Fusion HCI Systems

For more information about Prerequisites of IBM Fusion HCI system, see Planning and prerequisites.

For more information about Deploying IBM Fusion HCI System, see Deploying IBM Fusion HCI System.

For more information about how to deploy Global Data Platform service using IBM Fusion HCI Systems, see Global Data Platform.

For more information about IBM Fusion HCI Systems storage class, see IBM Storage Scale.

IBM Storage Scale Container Native

The following storage class is required by IBM Cloud Pak for AIOps, and is created when IBM Storage Scale Container Native is installed.

Storage provider	Storage class name	Large block storage class name
IBM Storage Scale Container Native	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc

This class is used as both the ReadWriteMany storage class and large block storage class when you are installing IBM Cloud Pak for AIOps. This StorageClass includes a parameter to set permissions of data within the StorageClass to **`shared: true`**, which is required to support the Kubernetes SubPath feature. For more information about the permissions field for the class, see the IBM Spectrum Scale CSI Driver documentation.

Installing IBM Storage Scale Container Native

IBM Storage Scale Container Native is available for purchase through the IBM Storage Suite for IBM Cloud Paks. IBM Spectrum Scale is a cluster file system that provides concurrent access to a single file system or set of file systems from multiple nodes. The nodes can be SAN-attached, network attached, a mixture of SAN-attached and network attached, or in a shared nothing cluster configuration. This enables high-performance access to this common set of data to support a scale-out solution or to provide a high availability platform. IBM Storage Scale Container Native Storage Access must be at version 5.1.1.3 or higher, with IBM Spectrum Scale Container Storage Interface version 2.3.0 or higher.

For more information, see the IBM Storage Scale Container Native documentation.

To use IBM Storage Scale Container Native with IBM Cloud Pak for AIOps, you do not require a separate license. You can use up to 12 TB of IBM Storage Scale Container Native storage for up to 36 months, fully supported by IBM, within your production environments (Level 1 and Level 2). If you exceed these terms, a separate license is required.

To install and use IBM Storage Scale Container Native, your cluster must meet the requirements in the IBM Storage Scale Container Native documentation.

To install IBM Storage Scale Container Native and the IBM Spectrum Scale Container Storage Interface, follow the IBM Storage Scale Container Native installation documentation.

If you encounter any errors or issues with installing or using IBM Storage Scale Container Native or the IBM Spectrum Scale Container Storage Interface, refer to the following documentation:

- IBM Storage Scale Container Native
- IBM Spectrum Scale Container Storage Interface

Portworx

The following storage classes are required by IBM Cloud Pak for AIOps, and must be created using the instructions in the following section:

Storage provider	Storage class name	Large block storage class name
Portworx	px-csi-aiops	px-csi-aiops
Portworx (multi-zone HA)	px-csi-aiops-mz	px-csi-aiops-mz

Installing Portworx

Important: `sharedv4` volumes require NFS ports to be open. For more information, see the Portworx documentation Open NFS Ports.

1. Install the Portworx operator and configure a Portworx StorageCluster.

   Two editions of Portworx are available: Portworx Enterprise and Portworx Essentials. Portworx Enterprise is suitable for production deployments. Portworx Essentials is suitable only for demonstration deployments, as it can be used only on clusters of five nodes or less, and includes storage size limits. For more information, see the Portworx documentation Installing Portworx on Openshift.

   Note: You must be a cluster administrator to install Portworx on the cluster.

2. Define a custom Portworx storage class.

   The custom Portworx storage class will be used for file and block storage. The storage class is scoped to the cluster, so setting the project (namespace) is not required.

   If you are not using the Multi-zone HA technical preview, then use Option 1 to define **`px-csi-aiops`**. If you are using the Multi-zone HA technical preview, then use Option 2 to define **`px-csi-aiops-mz`**.

   Option 1: Define `px-csi-aiops`

   Log in to your OpenShift cluster's console. Click the plus icon on the upper right to open the **Import YAML** dialog box, paste in the following content, and then click **Create**.

```
kind: StorageClass
apiVersion: storage.k8s.io/v1
metadata:
  name: px-csi-aiops
provisioner: pxd.portworx.com
parameters:
  fs: xfs
  io_profile: db_remote
  repl: '2'
reclaimPolicy: Delete
allowVolumeExpansion: true
volumeBindingMode: Immediate
```

   Option 2: Define `px-csi-aiops-mz`

   Log in to your OpenShift cluster's console. Click the plus icon on the upper right to open the **Import YAML** dialog box, paste in the following content, and then click **Create**.

```
kind: StorageClass
apiVersion: storage.k8s.io/v1
metadata:
  name: px-csi-aiops-mz
provisioner: pxd.portworx.com
parameters:
  fs: xfs
  io_profile: db_remote
  repl: '3'
reclaimPolicy: Delete
allowVolumeExpansion: true
volumeBindingMode: Immediate
```

AWS native storage

The following storage classes are required by IBM Cloud Pak for AIOps. **`gp3-csi`** is created for you, but you must create **`efs-sc`** using the instructions in the following section.

Storage provider	Storage class name	Large block storage class name
AWS native storage (without OADP backup and restore)	gp3-csi	gp3-csi
AWS native storage (with OADP backup and restore)	efs-sc	gp3-csi

Amazon Elastic Block Store (EBS) provides block storage - the storage class is **`gp3-csi`**, and is created when ROSA is installed. Amazon Elastic File System (EFS) provides file storage - the storage class is **`efs-sc`**. You must create the **`efs-sc`** storage class using the instructions in the following section.

Installing AWS native storage

For more information about Amazon Web Services (AWS) native storage, see Cloud Storage on AWS in the AWS documentation.

For more information, see **`Setting up the AWS EFS CSI Driver Operator`** and **`Creating the AWS EFS storage class`** in the Red Hat OpenShift documentation. You can also review the information in the Red Hat article Enabling the AWS EFS CSI Driver Operator on ROSA.

Network requirements

IBM Cloud Pak for AIOps uses ports to establish communication within OpenShift Container Platform and to the external integrations. Review the list of ports that need to be exposed for use in inbound and outbound communication with IBM Cloud Pak for AIOps.

Inbound communication ports

Inbound communication ports are used to establish connection from external sources to IBM Cloud Pak for AIOps capabilities. IBM Cloud Pak for AIOps exposes the following ports to achieve this communication.

- *TCP 80*: Default HTTP port.
- *TCP 443*: Default HTTPS port.
- *TCP 4100*: Used for Tabular Data Stream to connect to the on-prem IBM Tivoli Netcool/OMNIbus.

Notes:

- TCP 80 and TCP 443 ports must be available on all nodes, including master, worker, and storage nodes. These are the standard ports for HTTP/HTTPS inbound connections as defined by the OpenShift Container Platform routes. OpenShift Container Platform routes provide an abstraction for an external access so you do not have to deal directly with load balancers, inbound controllers, and other networking components.
- Cloud Pak for AIOps pods use only the standard ports such as port 80 or port 443 as defined by OpenShift Container Platform routes for HTTP/HTTPS inbound connections. The inbound connections from external sources can include browsers for accessing the console, an external Kafka client that needs to place data on a Kafka topic, Slack inbound data, and more.
- TCP 4100, TCP 16311, and TCP 9081 ports must be available on the worker nodes.

Connect to externally hosted probes

If you plan to connect to externally hosted probes to ObjectServers in Cloud Pak for AIOps, NodePorts are required. You can map any available port from the range of permissible ports for NodePort services to the target 4100 port. Hence, the port that matters from an inbound network perspective is the port that is used in the NodePort definition.

For more information about external probes that connect to ObjectServers (primary and backup), see Configuring the Cloud system.

Outbound communication ports

Cloud Pak for AIOps needs access to outbound ports to establish connection for probes and integrations.

- **IBM Tivoli Netcool/OMNIbus integration**

  For Netcool/OMNIbus integration, the bulk of data transfer is usually done over Tabular Data Stream port 4100 on the Netcool side. Cloud Pak for AIOps is able to establish a connection to 4100 port from each of the worker nodes. The Netcool/OMNIbus integration uses the IDUC port. IDUC indicates which alerts are inserted, deleted, or updated since the last IDUC cycle, which allows the integration to know what to request. This integration initially connects to ObjectServer by using Tabular Data Stream and then ObjectServer announces the host and port to use for IDUC. Therefore, firewall rules allow connectivity to the IDUC port.

  Notes:

  - If a firewall prevents Cloud Pak for AIOps connecting to Netcool on your VMs, you need to update the firewall rules to correct this situation.
  - The Netcool admin can modify the default 4100 port. It is recommended to engage the Netcool admin so that the admin can confirm all the ports for the Netcool components, such as ObjectServers, and Netcool/Impact.

  For more information about Netcool/OMNIbus to Cloud Pak for AIOps integration, see Creating IBM Netcool Operations Insight ObjectServer integrations.

  For more information about IDUC port, see the following links:

  - Set up the Netcool OMNIbus ObjectServer IDUC port.
  - Specifying the IDUC port
- **IBM Tivoli Netcool/Impact integration**

  The default ports for Netcool/Impact integration are 16311 and 9081. The 16311 port is used to access the GUI and the 9081 port is used to access the Netcool/Impact API.

  Netcool/Impact admin can decide to use different ports. It is recommended to get all the ports directly from admin in case the default ports have changed.

  For more information about Netcool/Impact to Cloud Pak for AIOps integration, see Creating IBM Tivoli Netcool/Impact integrations.

- **Probes**

  For probes that send events directly to Cloud Pak for AIOps, the IDUC port that is specified for the on-prem ObjectServer configuration needs to allow connectivity for Cloud Pak for AIOps. This IDUC port needs to be accessible from each of the worker nodes.

  In environments where a firewall is enabled between the servers or where iptables are configured on the servers, the `ncp_g_event` process can connect to the main ObjectServer listening port but might fail to connect to the IDUC port. While the main ObjectServer listening port uses a fixed port, the IDUC listening port is randomly selected by default. A fixed IDUC listening port must be specified to define firewall rules or iptables settings that allow IBM Tivoli Network Manager to connect to the ObjectServer on the IDUC listening port.

  For more information about IDUC port, see the following links:

  - Set up the Netcool OMNIbus ObjectServer IDUC port.
  - Specifying the IDUC port
- **Other integrations**

  For integrations such as Netcool, ELK, Splunk, Humio, Mezmo and topology observers, Cloud Pak for AIOps uses a PULL model.

  The configurations of these integrations (endpoint exposed by the external source) dictate the port and connection parameters that Cloud Pak for AIOps uses to pull data, such as event and log from those external systems. The port number that is used by that external system depends on how the external integration was configured. Cloud Pak for AIOps does not dictate the value of port number. The outbound ports for each of these integrations need to be open on each of the worker nodes.

In some cases, these integrations can exist within the same intra-network where Cloud Pak for AIOps is installed. In other cases, you might be using a SaaS offering of the integrations (such as Instana or New Relic). For such cases, if you do not want to allow direct outbound access from the OpenShift Container Platform cluster to the SaaS service, you can use the Secure Tunnel approach. This approach requires a VM with internet access, which allows a VM to connect to the SaaS instance.

For more information about the Secure Tunnel approach, see Secure Tunnel.

For more information about other integrations, see the following topics.

  - Dynatrace Events integration
  - Dynatrace Topology integration
  - Splunk Events integration
  - SevOne Events integration
  - SevOne Topology integration
  - ITNM Topology integration

- **Internal communication within the OpenShift Container Platform cluster where Cloud Pak for AIOps is installed**

  Cloud Pak for AIOps internally uses other ports such as 8080, 8383 and 8686 for communication between its own pods, which run on the same OpenShift Container Platform cluster.

High Availability (HA) considerations

You can set up high availability (HA) for your IBM Cloud Pak® for AIOps deployment by selecting a production (large) sizing profile.

IBM Cloud Pak for AIOps

HA configures your deployment with extra replication of its services, and affinity rules to provide redundancy. A HA configuration allows your deployment to tolerate upgrades and service interruptions to a portion of the infrastructure. Failures in the following domains are minimized:

- individual pod failure: Red Hat OpenShift recovers individual failed pods.
- cluster node failure (master or worker): Red Hat OpenShift recovers non-stateful deployments.

For a high availability deployment, you must set a value of **`large`** in your IBM Cloud Pak for AIOps **`Installation`** custom resource when you create your IBM Cloud Pak for AIOps instance. Sizing is configured in your IBM Cloud Pak for AIOps installation custom resource with the parameter **Capacity** (Red Hat® OpenShift® Container Platform UI) or **spec.size** (Red Hat OpenShift CLI), and can be set to **`small`** for starter deployments or **`large`** for production deployments.

Multi-zone HA

A technology preview of installing IBM Cloud Pak for AIOps on a multi-zone architecture is also available. For more information, see Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA).

Multi-region cold standby disaster recovery

A multi-region cold standby disaster recovery solution for IBM Cloud Pak for AIOps is also available. For more information, see Multi-region cold standby disaster recovery

Infrastructure Automation

For more information about high availability (HA) considerations for your Infrastructure Automation deployment, see High Availability (HA) considerations.

Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA)

BETA The use of the multi-zone high availability (HA) deployment architecture for IBM Cloud Pak for AIOps is available only for technology preview, and is not for production usage.

Review the following sections:

- Overview
- Installing on a multi-zone architecture
- Limitations while workloads are rescheduled

Overview

IBM Cloud Pak® for AIOps is starting to implement multi-zone availability, as provided by the Red Hat® OpenShift® Container Platform. This feature is not available for deployments of IBM Cloud Pak for AIOps on Linux®.

Installing IBM Cloud Pak for AIOps on a Red Hat OpenShift cluster that spans multiple availability zones improves resiliency. The distribution of pod replicas in different zones means that if a zone becomes unavailable, then remaining replicas in other zones are still able to service requests. Red Hat OpenShift is also able to reschedule failed nodes' workloads from a zone that is subject to an outage to nodes in an alternative healthy zone.

For more information about the benefits of multi-zone architectures, see Running in multiple zones in the Kubernetes documentation.

Red Hat OpenShift tolerates nodes (and by extension zones) being down for five minutes, in addition to a node monitoring interval. For that reason, and accounting for the additional image pull and pod startup times, node and zone failures take approximately six minutes to start recovering. For more information, see Using remote worker node at the network edge: Kubernetes zones in the Red Hat OpenShift documentation.

Note: Multi-zone availability is only supported for production deployments of IBM Cloud Pak for AIOps. A starter deployment of IBM Cloud Pak for AIOps can be deployed on a multi-zone architecture, but it will not be highly available.

Installing on a multi-zone architecture

Use the following steps to install IBM Cloud Pak for AIOps on a multi-zone architecture.

1. Prepare your cluster

   Before you install IBM Cloud Pak for AIOps, you must ensure that your Red Hat OpenShift cluster is configured for multi-zone by labeling the cluster nodes with a zone. Cluster administrator permission is required to add labels to your nodes.

   If you are installing IBM Cloud Pak for AIOps on a cloud platform, then refer to your cloud provider's documentation to learn how to select a multi-zone type when you are setting up your cluster, and then skip to step 2, Configure storage.

   If you are installing directly on Red Hat OpenShift on-premises, then label your Red Hat OpenShift cluster nodes as follows.

   1. Label cluster nodes with zones.

      Distribute your cluster nodes across three availability zones, ensuring that you have a cluster master node in each availability zone. Allocate each node to an availability zone by labeling the node with the zone:

      ```
      oc label node <node-name> topology.kubernetes.io/zone=<zone-name>
      ```

      Where

      - `<node-name>` is the fully qualified domain name of your node, for example *worker0.mycluster.subdomain.example.com*.
      - `<zone-name>` is the name of the zone that you want the node to be in.

   2. Label cluster nodes with regions.

      IBM Cloud Pak for AIOps has a dependency that requires the Kubernetes region label to be set on each node. The region label can be set to the same value on all nodes.

      ```
      oc label node <node-name> topology.kubernetes.io/region=<region-name>
      ```

      Where

      - `<node-name>` is the fully qualified domain name of your node, for example *worker0.mycluster.subdomain.example.com*.
      - `<region-name>` is the region name.

   When the `topology.kubernetes.io/zone` label is specified for the nodes in a cluster, Kubernetes tries to schedule a ReplicaSet's pods on different worker nodes in different zones. For example, a deployment of three replicas should result in one replica being deployed in each zone of a three zone cluster.

2. Configure storage

   Refer to your storage provider's documentation for instructions on configuring storage classes for a multi-zone configuration that enables data to remain available if a cluster node becomes unavailable.

3. Install IBM Cloud Pak for AIOps

   Starter deployments are not configured to support multi-zone HA. Use the following instructions to install a production installation of IBM Cloud Pak for AIOps.

   Installing IBM Cloud Pak for AIOps (Production installation)

   IBM Cloud Pak for AIOps uses a preferred scheduling approach instead of a hard cluster topology requirement. This approach provides greater administrative flexibility and helps IBM Cloud Pak for AIOps to remain functional despite any cluster topology issues. Red Hat OpenShift distributes pods on the nodes according to node availability and other considerations such as available resources, node taints, or whether an image already exists on a node. These considerations might sometimes conflict.

   The installation procedure has an optional step to run a status checker script. This script reports whether pods are optimally distributed for resilience within your multi-zone cluster. Manual intervention might sometimes be necessary to move pods to the correct zone. The deletion of one or more incorrectly placed pods is usually sufficient, but it may be necessary to cordon nodes in a zone to help direct Red Hat OpenShift to distribute the pods to the proper zone. For more information about rebalancing, see Rebalancing workloads on a multi-zone architecture (multi-zone HA).

   Note: The Secure Tunnel function is enhanced to better handle zone outages. If you use Secure Tunnel, when you configure connector and tunnel worker replicas, ensure that the replica count is equal to or greater than the number of zones in your environment. The number of replicas is preferably a multiple of the number of zones. For example, if your environment has three zones then you might configure two replicas for each zone, to give a total of six replicas. For more information about configuring connector and tunnel replicas, see Creating Secure Tunnel connections.

Some resources might not failover as expected, and might require intervention. Contact IBM Support if you encounter any problems when you are using this technology preview.

Limitations while workloads are rescheduled

If the following functions are affected by a zone outage, then they are compromised until Red Hat OpenShift reschedules the affected workloads to nodes in an unaffected zone. This takes approximately six minutes.

- Integrations do not collect or forward data.

- Alerts, Events, and Incidents from IBM® Netcool® Operations Insight® probes are paused.
- IBM® Netcool® Agile Service Manager observers do not run.
- AI model management UI is not accessible.
- AI training may be paused and there is no new training of selected analytics.
- You cannot view, edit, delete, create, or deploy integrations.
- Insights Dashboard is not accessible.
- Resource enrichment functionality, which matches resources to resources, updates status, and adds queriable tags is paused.
- The matching of resources to events is paused.
- Timed jobs such as alert expiration and closure do not run.
- Netcool Operations Insight probe data archiving is paused.
- Secure tunnel controller pod - changes to the tunnel connections or application mappings fail. If one of the connection worker pods is not available for Secure Tunnel to use then performance might be impacted, depending on the current workload.
- Runbook Automation: SSH actions and HTTP actions that are running might lose connection to their target if the outage affects the pod that is running them. In this scenario, no further output is received from the target. For SSH actions, the execution of the remote script on the target machine stops. Ansible actions are run by the Ansible Automation Platform. For HADR considerations of Ansible actions, refer to the Ansible Automation Platform documentation.
- No new usage metrics

Multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps

Multi-region cold standby disaster recovery (DR) enables the restoration of your IBM Cloud Pak for AIOps deployment if an unrecoverable failure impacts the deployment or its hosting cluster, data center, or region.

Overview

The multi-region cold standby disaster recovery solution for IBM Cloud Pak for AIOps uses IBM Fusion to create and restore backups of your IBM Cloud Pak for AIOps deployment and its data. For more information about IBM Fusion, see the Fusion documentation.

IBM Fusion uses the concept of a hub and spoke. A Red Hat® OpenShift® Container Platform cluster that has an IBM Fusion backup & restore service installation on it is the hub cluster. The hub manages the backups, and backups can also be taken or restored on a hub cluster. A Red Hat OpenShift cluster that has an IBM Fusion backup & restore agent installation on it is a spoke cluster. Backups can be taken or restored on a spoke, but the spoke cannot manage the backups.

IBM Fusion takes a backup of your IBM Cloud Pak for AIOps deployment, and stores it in external object storage. If a problem occurs that renders your IBM Cloud Pak for AIOps deployment unusable, then the backup can be restored to a Red Hat OpenShift spoke cluster. The entire IBM Cloud Pak for AIOps deployment is restored, along with its data.

Entitlement to IBM Cloud Pak for AIOps provides you with entitlement to the IBM Fusion Data Foundation service in internal deployment mode only. To implement multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps, you must purchase a full IBM Fusion license for access to the backup and disaster recovery features. For more information, see the license terms.

Restrictions

- IBM Fusion and the IBM Cloud Pak for AIOps deployment to be backed up must be installed on the same Red Hat OpenShift cluster.
- The backup and restore procedures cannot be used on offline (air gapped) deployments of IBM Cloud Pak for AIOps.
- The backup and restore procedures cannot be used if IBM Cloud Pak for AIOps is installed with Infrastructure Automation.
- The backup and restore procedures cannot be used on `AllNamespace` deployments of IBM Cloud Pak for AIOps. For more information about installation modes, see Operator installation mode.
- If IBM Cognos® Analytics is installed, it is not backed up or recovered.
- User interface customizations are not backed up or restored.

Before you begin

Red Hat OpenShift

Ensure that you meet the following prerequisites for the hub cluster, and also for the spoke cluster if you are using one:

- The Red Hat OpenShift version is supported by IBM Cloud Pak for AIOps and IBM Fusion v2.8.x or v2.9.x.
  - IBM Cloud Pak for AIOps: For more information, see Supported Red Hat OpenShift versions.
  - IBM Fusion: For more information, see Prerequisites in the IBM Fusion documentation.
- The Red Hat OpenShift command-line interface (oc) is installed. For more information, see the instructions in Getting started with the Red Hat OpenShift CLI in the Red Hat OpenShift documentation.
- You are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).

Storage

Ensure that you meet the following prerequisites for your persistent and external storage.

- In addition to your IBM Cloud Pak for AIOps deployment's persistent storage, you must have external object storage available for IBM Fusion to use as the backup storage location. This is where the IBM Cloud Pak for AIOps volume backups will be stored. This can be any S3 compatible storage, or Microsoft® Azure Blob Storage.
- The amount of external object storage that is required is affected by the amount of data to be stored, the change rate of the data, and the storage efficiencies that can be made from compression and deduplication. As a guide, for a 30-day retention period, you must have object storage capacity equivalent to a minimum of 125% of your IBM Cloud Pak for AIOps deployment's persistent storage. For example, if you have 100 GB of persistent storage for IBM Cloud Pak for AIOps, then you must have 125 GB of object storage available for backups.
- The persistent storage that IBM Cloud Pak for AIOps uses must be Container Storage Interface (CSI) compatible, and must support volume snapshot and restore. The CSI driver must be v1 or higher.

- If you are using Portworx as your storage provider, then IBM Fusion must be at v2.9.0 or higher, or backup and restore will fail.
- PersistentVolumes (PVs) must be created with `volumeMode` set to *Filesystem*.
- The storage class that is used by IBM Cloud Pak for AIOps must have `volumeBindingMode` set to *Immediate*, and `allowVolumeExpansion` set to *true*.

For more information, see the `Backup & Restore` section in System requirements in the IBM Fusion documentation.

Backup and restore procedures

Use the instructions in the following sections to backup or restore an IBM Cloud Pak for AIOps deployment.

- Multi-region cold standby disaster recovery: Backing up IBM Cloud Pak for AIOps
- Multi-region cold standby disaster recovery: Restoring IBM Cloud Pak for AIOps
- Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps

Multi-region cold standby disaster recovery: Backing up IBM Cloud Pak for AIOps

Use IBM Fusion to create a backup of your IBM Cloud Pak for AIOps deployment.

Backup procedure

Ensure that you meet the prerequisites in Before you begin.

Use the following instructions to install IBM Fusion on the same Red Hat OpenShift cluster as IBM Cloud Pak for AIOps, and then create a backup of IBM Cloud Pak for AIOps.

1. Ensure that you have a VolumeSnapshotClass
2. Install IBM Fusion
3. Deploy the IBM Fusion Backup & Restore service
4. Configure the IBM Fusion Backup & Restore service for IBM Cloud Pak for AIOps

1. Ensure that you have a VolumeSnapshotClass

To enable IBM Fusion backups, you must have a `VolumeSnapshotClass` defined for one of the storage classes that host IBM Cloud Pak for AIOps. For more information, see Prerequisites in the IBM Fusion documentation.

Run the following command to check whether a `VolumeSnapshotClass` is defined already:

```
oc get volumesnapshotclass
```

If the preceding command does not return anything, then you do not have a `VolumeSnapshotClass` defined. Refer to your storage provider's documentation to create one.

2. Install IBM Fusion

You must install IBM Fusion v2.8.x or v2.9.x.

Follow the *Installing* instructions for your Red Hat OpenShift deployment type in Deploying IBM Fusion in the IBM Fusion documentation. Accept the default values.

Note: As you are installing IBM Fusion on the same Red Hat OpenShift cluster as IBM Cloud Pak for AIOps, you already have an entitlement pull secret configured.

3. Deploy the IBM Fusion Backup & Restore service

1. Install the IBM Fusion Backup & Restore service.

   Follow the instructions in Backup and restore hub in the IBM Fusion documentation.

   The `ibm-backup-restore` project (namespace) is created, and the backup and restore service is installed in that project.

2. Configure the backup storage location for IBM Fusion to store the IBM Cloud Pak for AIOps backups in.

   The backup storage location must be external object storage, and can be any S3 compatible storage or Microsoft® Azure Blob Storage.

   Follow the instructions in Adding a backup storage location in the IBM Fusion documentation.

3. Create a backup policy.

   The backup policy specifies the backup location, frequency, and retention period of the backup. Specify the backup storage location that you created in the previous step as the backup location.

   Follow the instructions in Creating backup policy in the IBM Fusion documentation.

4. Select the IBM Cloud Pak for AIOps application that you want to backup, and assign the backup policy to it.

Follow the instructions in Selecting applications for protection in the IBM Fusion documentation.

Important: Before you select **Assign** in the user interface, you must deselect **Run backup now** to prevent the backup from running immediately.

5. Find the name of your policy assignment.

   Your policy assignment name is the IBM Cloud Pak for AIOps installation namespace concatenated with the backup policy name. Run the following command to find it, and then make a note of it:

   ```
   oc get fpa -n ibm-spectrum-fusion-ns
   ```

4. Configure the IBM Fusion Backup & Restore service for IBM Cloud Pak for AIOps

1. Run the following commands to set the environment variables that you need.

   ```
   export PROJECT_CP4AIOPS=<namespace>
   export CUSTOM_PROFILE=<custom_profile>
   export POLICY_ASSIGNMENT_NAME=<policy_assignment_name>
   ```

   Where:

   - **<namespace>** is the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in, for example **cp4aiops**.
   - **<custom_profile>** is blank unless IBM Sales representatives and Business Partners used the custom sizing tool to supply you with a custom profile ConfigMap to customize your deployment. If you were supplied with a custom profile ConfigMap, then this is the name of your custom profile ConfigMap, usually **aiops-custom-size-profile**.
   - **<policy_assignment_name>** is the policy assignment name that you found in the previous step.

2. Find your installation name and set an environment variable for it.

   1. Find the name of your IBM Cloud Pak for AIOps installation.

      ```
      oc get installation -n ${PROJECT_CP4AIOPS}
      ```

      Example output, where **ibm-cp-aiops** is the name of the IBM Cloud Pak for AIOps installation:

      ```
      NAME          PHASE    LICENSE   STORAGECLASS STORAGECLASSLARGEBLOCK AGE
      ibm-cp-aiops  Running  Accepted  rook-cephfs  rook-ceph-rbd          34h
      ```

   2. Export an environment variable with the name of your installation.

      ```
      export INSTALLATION_NAME=<name>
      ```

      Where **<name>** is the name returned by the previous command, for example **ibm-cp-aiops**.

3. Run the following commands to add labels to IBM Cloud Pak for AIOps resources so that they are correctly identified.

   ```
   oc -n $PROJECT_CP4AIOPS label secret ${INSTALLATION_NAME}-edb-secret manual=${INSTALLATION_NAME}-edb-secret
   oc -n $PROJECT_CP4AIOPS label secret ${INSTALLATION_NAME}-redis-secret manual=${INSTALLATION_NAME}-redis-secret
   oc -n $PROJECT_CP4AIOPS label secret ibm-zen-secret-jwks manual=ibm-zen-secret-jwks
   oc -n $PROJECT_CP4AIOPS label secret ibm-zen-secret-jwt manual=ibm-zen-secret-jwt
   oc -n $PROJECT_CP4AIOPS label secret ibm-zen-secret-jwt-private manual=ibm-zen-secret-jwt-private
   oc -n $PROJECT_CP4AIOPS label secret aiopsedge-config-encryption-history manual=aiopsedge-config-encryption-history
   oc -n $PROJECT_CP4AIOPS label secret platform-auth-ldaps-ca-cert manual=platform-auth-ldaps-ca-cert
   oc -n $PROJECT_CP4AIOPS label secret ibm-entitlement-key manual=ibm-entitlement-key-secret
   oc -n $PROJECT_CP4AIOPS label subscriptions.operators.coreos.com ibm-aiops-orchestrator manual=ibm-aiops-
   orchestrator
   ```

4. Download the IBM Cloud Pak for AIOps backup and restore IBM Fusion recipe.

   The IBM Fusion recipe defines the sequence of actions and checks that IBM Fusion must use for the backup and restore of IBM Cloud Pak for AIOps resources and PVCs.

   Download the recipe **aiops-backup-restore.yaml**, from github.com/IBM.

5. Adjust the recipe if you have a non-default installation name.

   If your installation name is not **ibm-cp-aiops**, then edit the recipe that you downloaded, and alter all occurences of **ibm-cp-aiops** to be your installation name.

6. Adjust the recipe for custom sizing.

   IBM Sales representatives and Business Partners may have used a custom sizing tool to supply you with a custom profile to customize your IBM Cloud Pak for AIOps deployment at installation time.

   If IBM Sales representatives and Business Partners did not supply you with a custom profile, then skip this step.

   If IBM Sales representatives and Business Partners supplied you with a custom profile, then add a label to the custom profile ConfigMap in your IBM Cloud Pak for AIOps deployment. Run the following command:

   ```
   oc label cm ${CUSTOM_PROFILE} cm=aiops-custom-size-profile
   ```

7. Create the IBM Cloud Pak for AIOps recipe custom resource.

   Run the following command to create the recipe custom resource.

   ```
   oc apply -f aiops-backup-restore.yaml
   ```

8. Configure your policy assignment to use the IBM Cloud Pak for AIOps back and restore recipe.

   Patch the policy assignment with the details of the IBM Cloud Pak for AIOps back and restore recipe.

   ```
   oc -n ibm-spectrum-fusion-ns patch policyassignment ${POLICY_ASSIGNMENT_NAME} --type merge  -p '{"spec":{"recipe":
   {"name":"aiops-backup-restore-recipe", "namespace":"ibm-spectrum-fusion-ns"}}}'
   ```

What to do next

Backups occur according to the schedule that you set in your policy. If you want to run a backup immediately, follow the instructions in Backup now.

You can monitor the progress of the backup from **Backup & restore** > **Jobs** in the IBM Fusion user interface.

To view the IBM Fusion logs, or to see the resources that were backed up, see Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps.

Multi-region cold standby disaster recovery: Restoring IBM Cloud Pak for AIOps

Use IBM Fusion to restore your IBM Cloud Pak for AIOps deployment from backup.

Restore procedure

IBM Fusion recovers the IBM Cloud Pak for AIOps instance to a working state on a target cluster, along with its data. Your target cluster can be the hub cluster, or a different Red Hat OpenShift cluster (a spoke).

Ensure that you meet the prerequisites in Before you begin. User interface customizations are not restored.

Follow the steps for Restoring to the hub cluster or Restoring to a spoke cluster.

Restoring to the hub cluster

If you are restoring IBM Cloud Pak for AIOps to the same Red Hat OpenShift cluster that you created your backup on, then you must completely uninstall your IBM Cloud Pak for AIOps deployment, and remove the deployment namespaces from it (usually **cp4aiops**). The Red Hat OpenShift cluster must not have any residual IBM Cloud Pak for AIOps artifacts. For more information, see Uninstalling IBM Cloud Pak for AIOps.

1. Get the entitlement key.

   Follow the instructions in Obtaining the entitlement key in the IBM Fusion documentation.

2. Create a global pull secret.

   Follow the instructions in Creating image pull secret in the IBM Fusion documentation.

3. Create the required catalogs.

   Follow the instructions in Create the catalog sources.

4. Install Cert Manager

   Skip this step if a certificate manager is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager, then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

   For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-cert-manager
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-cert-manager-operator-group
        namespace: ibm-cert-manager
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      metadata:
        name: ibm-cert-manager-operator
        namespace: ibm-cert-manager
      spec:
        channel: v4.2
        installPlanApproval: Automatic
        name: ibm-cert-manager-operator
        source: ibm-cert-manager-catalog
      ```

```
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-cert-manager get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

   ```
   NAME                                       READY   STATUS    RESTARTS   AGE
   cert-manager-cainjector-674854c49d-vstq4   1/1     Running   0          8d
   cert-manager-controller-646d4bd6fd-zwmqm   1/1     Running   0          8d
   cert-manager-webhook-8598787c8-s41kt       1/1     Running   0          8d
   ibm-cert-manager-operator-c96957695-dkxnm  1/1     Running   0          8d
   ```

5. Install the License Service

   Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-licensing-operator-group
        namespace: ibm-licensing
      spec:
        targetNamespaces:
        - ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      metadata:
        name: ibm-licensing-operator-app
        namespace: ibm-licensing
      spec:
        channel: v4.2
        installPlanApproval: Automatic
        name: ibm-licensing-operator-app
        source: ibm-licensing-catalog
        sourceNamespace: openshift-marketplace
      EOF
      ```

   2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

      ```
      oc -n ibm-licensing get pods
      ```

      Example output for a successful IBM Cloud Pak® foundational services License Service installation:

      ```
      NAME                                              READY   STATUS    RESTARTS   AGE
      ibm-licensing-operator-db4cd746c-xzmlf            1/1     Running   0          8d
      ibm-licensing-service-instance-596b99588f-76cc5   1/1     Running   0          8d
      ```

   For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

6. Update the IBM Fusion Backup & Restore transaction manager cluster roles.

   Run the following command:

   ```
   oc get clusterrole transaction-manager-ibm-backup-restore -o json | jq '.rules += [{"verbs":
   ["get","list"],"apiGroups":["orchestrator.aiops.ibm.com"],"resources":["installations"]},{"verbs":
   ["get","list"],"apiGroups":["ai-manager.watson-aiops.ibm.com"],"resources":["aimanagers"]},{"verbs":
   ["get","list"],"apiGroups":["lifecycle.ir.aiops.ibm.com"],"resources":["lifecycleservices"]}]' | oc apply -f -
   ```

7. Follow the instructions in Restoring the application in the IBM Fusion documentation.

   Select **Same cluster**, and then for **Project destination** select *Use the same project the application is already using*. Accept the default values for the other fields.

   Note: You might notice that the `aiops-configmaps` resource group shows as failed under the **Restore sequence** section of the IBM Cloud Pak for AIOps restore recipe but the overall restore is successful and works as intended.

8. Delete any duplicate observer jobs on the restored cluster.

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. For any duplicate jobs, click the options menu (three vertical dots) and click **Delete**.

9. From the IBM Cloud Pak for AIOps console, select and edit each `incident` policy that utilises a `ticket` integration, and manually reassign the relevant ticketing system (Github/ServiceNow).

Restoring to a spoke cluster

If you are restoring IBM Cloud Pak for AIOps to a different cluster, ensure that your target cluster meets the prerequisites for an IBM Cloud Pak for AIOps deployment, and then install IBM Fusion and the IBM Fusion backup agent on it.

1. Spoke cluster prerequisites

- You must have the same storage provider and storage classes available for your target spoke cluster as you did for your IBM Cloud Pak for AIOps deployment on the hub cluster.
- The target spoke cluster must have the same deployment platform and Red Hat OpenShift version as the source hub cluster. Review the Planning section and ensure that the environment that you are restoring to meets the system requirements.
- The Red Hat OpenShift cluster that you restore on must not have a previous IBM Cloud Pak for AIOps deployment on it, and must not have any residual IBM Cloud Pak for AIOps artifacts or deployment namespaces (usually `cp4aiops`). If you need to uninstall IBM Cloud Pak for AIOps, see the instructions in Uninstalling IBM Cloud Pak for AIOps.

2. Install IBM Fusion on the target spoke cluster

    1. Get the entitlement key.

       Follow the instructions in Obtaining the entitlement key in the IBM Fusion documentation.

    2. Create a global pull secret.

       Follow the instructions in Creating image pull secret in the IBM Fusion documentation.

    3. Create the required catalogs.

       Follow the instructions in Create the catalog sources.

    4. Install IBM Fusion.

       You must install IBM Fusion v2.8.x or v2.9.x.

       Follow the `Installing` instructions for your Red Hat OpenShift deployment type in Deploying IBM Fusion in the IBM Fusion documentation. Accept the default values.

3. Install Cert Manager

   Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

   For more information about IBM Cloud Pak® foundational services Cert Manager, see Certificate Management in the IBM Cloud Pak foundational services documentation.

    1. Run the following command to create the resource definitions that you need:

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Namespace
metadata:
  name: ibm-cert-manager
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-cert-manager-operator-group
  namespace: ibm-cert-manager
---
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-cert-manager-operator
  namespace: ibm-cert-manager
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-cert-manager-operator
  source: ibm-cert-manager-catalog
  sourceNamespace: openshift-marketplace
EOF
```

    2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

```
oc -n ibm-cert-manager get pods
```

Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-cainjector-674854c49d-vstq4   1/1     Running   0          8d
cert-manager-controller-646d4bd6fd-zwmqm   1/1     Running   0          8d
cert-manager-webhook-8598787c8-s41kt       1/1     Running   0          8d
ibm-cert-manager-operator-c96957695-dkxnm  1/1     Running   0          8d
```

4. Install the License Service

   Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-licensing-operator-group
        namespace: ibm-licensing
      spec:
        targetNamespaces:
        - ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      metadata:
        name: ibm-licensing-operator-app
        namespace: ibm-licensing
      spec:
        channel: v4.2
        installPlanApproval: Automatic
        name: ibm-licensing-operator-app
        source: ibm-licensing-catalog
        sourceNamespace: openshift-marketplace
      EOF
      ```

   2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

      ```
      oc -n ibm-licensing get pods
      ```

      Example output for a successful IBM Cloud Pak® foundational services License Service installation:

      ```
      NAME                                              READY   STATUS    RESTARTS   AGE
      ibm-licensing-operator-db4cd746c-xzmlf            1/1     Running   0          8d
      ibm-licensing-service-instance-596b99588f-76cc5   1/1     Running   0          8d
      ```

   For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

5. Get connection YAML from the hub cluster.

   On the hub cluster, follow the **`Use the Fusion UI`** instructions in Connect clusters in the IBM Fusion documentation.

   When you have copied the connection snippet, return to these steps. The connection snippet is used in the next step to connect the hub and spoke clusters.

6. Install the **`Backup & Restore Agent`** on the spoke cluster, and connect the spoke cluster to the hub cluster.

   On the spoke cluster, follow the procedure in Backup & Restore spoke in the IBM Fusion documentation.

   For the **Hub Connection Snippet** field, use the connection snippet that you copied in the previous step. The storage classes must be the same storage classes that the IBM Cloud Pak for AIOps deployment on the hub cluster used.

7. On the spoke cluster, update the IBM Fusion Backup & Restore transaction manager cluster roles.

   Run the following command:

   ```
   oc get clusterrole transaction-manager-ibm-backup-restore -o json | jq '.rules += [{"verbs":
   ["get","list"],"apiGroups":["orchestrator.aiops.ibm.com"],"resources":["installations"]},{"verbs":
   ["get","list"],"apiGroups":["ai-manager.watson-aiops.ibm.com"],"resources":["aimanagers"]},{"verbs":
   ["get","list"],"apiGroups":["lifecycle.ir.aiops.ibm.com"],"resources":["lifecycleservices"]}]' | oc apply -f -
   ```

8. Follow the instructions in Restoring the application in the IBM Fusion documentation, and wait for the restore to complete.

   Select **New cluster**, and then accept the default values for the other fields.

Note: You might notice that the `aiops-configmaps` resource group shows as failed under the **Restore sequence** section of the IBM Cloud Pak for AIOps restore recipe but the overall restore is successful and works as intended.

9. Redeploy remote integrations.

   Re-run the bootstrap procedure for any remote connections that are configured.

   1. Log in to IBM Cloud Pak for AIOps console.
   2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
   3. For each remote integration, click the integration type on the **Manage integrations** tab of the Integrations page, then:
      1. Click the **Download** link in the **Remote deployment script** column for the integration.
      2. Click **Download as a sh-file** to download the deployment script as a `bootstrap.sh` file.
      3. From the Red Hat OpenShift CLI, switch to the target project (namespace).

         ```
         oc project <namespace>
         ```

         Where `<namespace>` is the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in, for example *cp4aiops*.
      4. Run the `bootstrap.sh` deployment script.

10. If you have secure tunnel connections, then re-create them. For more information, see Create the secure tunnel connection on your restored cluster.
11. Delete any duplicate observer jobs on the restored cluster.
    1. Log in to IBM Cloud Pak for AIOps console.
    2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
    3. For any duplicate jobs, click the options menu (three vertical dots) and click **Delete**.
12. From the IBM Cloud Pak for AIOps console, select and edit each `incident` policy that utilises a `ticket` integration, and manually reassign the relevant ticketing system (Github/ServiceNow).

What to do next

The restore takes a few hours to run. You are notified on the IBM Fusion user interface (UI) when the restore is complete. You can also monitor the progress of the restore from **Backup & restore** > **Jobs** in the IBM Fusion UI.

Important: If you restored to a spoke cluster, the URL and password for accessing the IBM Cloud Pak for AIOps console are different from the URL and password that you used on the hub cluster. Follow the steps in Access the Cloud Pak for AIOps console to find the new URL and password.

(Optional) After the restore is complete, you can verify the status of your deployment by using the steps in Verify your installation (CLI) or Verify your installation (console).

To view the IBM Fusion logs, or to see the resources that were backed up or restored, see Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps.

Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps

Troubleshoot your IBM Fusion backup or restore of IBM Cloud Pak for AIOps.

General troubleshooting

- Retrieve backup or restore logs
- List resources that were backed up or restored

Restore issues

- Policy configuration is not retained on the restored deployment
- PostgresSQL instance is out of sync after fusion restore

General troubleshooting tips

Retrieve backup or restore logs

1. Download `getRecipeWorkflow.sh` from github.com/IBM.
2. Obtain the job UID for the backup or restore job. The job UID can be obtained from the IBM Fusion user interface, or from the command-line.

   From the IBM Fusion user interface:

1. Select **Applications** from the left navigation menu.
2. Select the Application from the table, for example `filebrowser`.
3. Select **Backups**.
4. For the backup or restore job of interest, select the right ... menu and select **Details**.
5. Click the job name, for example `filebrowser-demo-daily-apps.test.stglabs.ibm.com-202311220800`.
6. Note the **Job ID** in the **Details** window, for example: `63eb6ea5-dc24-41ef-9fb7-199c48df1508`.`

From the command-line:

1. Open the YAML file for the backup custom resource. For example:

   ```
   oc get fbackup filebrowser-demo-daily-apps.test.stglabs.ibm.com-202311220800 -n ibm-spectrum-fusion-ns -o yaml
   ```

2. Locate the `uid` in `spec: metatdata`, for example: `uid: 63eb6ea5-dc24-41ef-9fb7-199c48df1508`.

3. Run `getRecipeWorkflow.sh` with the job UID.

   ```
   getRecipeWorkflow.sh <job_type> <job_uid>
   ```

   Where

   - `<job_type>` is `backup` or `restore`.
   - `<job_uid>` is the job UID that you obtained.

   Example command:

   ```
   getRecipeWorkflow.sh backup 63eb6ea5-dc24-41ef-9fb7-199c48df1508
   ```

List resources that were backed up or restored

1. Download `getResources.sh` from github.com/IBM.
2. Use step 2 in Retrieve backup or restore logs to get the job UID.
3. Run `getResources.sh` with the job UID.

   ```
   getReesources.sh <job_type> <job_uid>
   ```

   Where

   - `<job_type>` is `backup` or `restore`.
   - `<job_uid>` is the job UID that you obtained.

   Example command:

   ```
   getResources.sh backup 63eb6ea5-dc24-41ef-9fb7-199c48df1508
   ```

Troubleshooting restore issues

Policy configuration is not retained on the restored deployment

Incident policies that previously had a ticket integration are missing the ticket integration on the restored deployment. If GitHub or ServiceNow are configured, then external tickets are not created in them. The policy page has a **Warning** similar to the following example:

```
The previously selected ticket connection Github -mygit is no longer available. Please check the status of your connector.
```

Solution: From the IBM Cloud Pak for AIOps console, edit the policy and add the connection that is shown in the warning.

PostgresSQL instance is out of sync after fusion restore

After restore, an EDB Postgres instance has a different value for the Log Sequence Number (LSN), which means that it is not synchronized with the other instances.

1. If it is not already installed, install the `kubectl` plug-in.

   Run the following command:

   ```
   curl -sSfL \
   https://github.com/EnterpriseDB/kubectl-cnp/raw/main/install.sh | \
   sudo sh -s -- -b /usr/local/bin
   ```

2. Run the following command to check whether all the EDB Postgres instances are synchronized.

   ```
   oc cnp status ibm-cp-aiops-edb-postgres
   ```

   If a Postgres instance is not synchronized, then the value for `Current LSN` is not the same as the `Current LSN` for the other instances.

   Example output where a Postgres instance is not synchronized: `worker9.ir-backend-backup-acme.com` has a different Log Sequence Number (LSN):

```
 Name                          Database  Current     Replication            Status  QoS         Manager  Node
                               Size      LSN         role                                       Version
 ibm-cp-aiops-edb-postgres-1   83 MB     6/C214B440  Primary                OK      Burstable   1.18.13  worker7.ir-
backend-backup-acme.com
 ibm-cp-aiops-edb-postgres-2   82 MB     6/C214B440  Standby (async)        OK      Burstable   1.18.13  worker2.ir-
backend-backup-acme.com
 ibm-cp-aiops-edb-postgres-3   82 MB     6/A124B330  Standby (file based)   OK      Burstable   1.18.13  worker9.ir-
backend-backup-acme.com
```

Solution: If one or more of the Postgres instances are not synchronized, follow the instructions in Postgres EDB database crashes.

Security considerations

IBM Cloud Pak® for AIOps supports different mechanisms for securing your environment and your data.

IBM Cloud Pak for AIOps builds on the security features provided by Red Hat OpenShift Container Platform by creating Security Context Constraints (SCC), service accounts, and roles. These features ensure that IBM Cloud Pak for AIOps pods and users have the lowest level of privileges to the Red Hat OpenShift Container Platform that is needed for them. These features protect sensitive customer data with strong encryption controls and improve the oversight of access control across applications and the platform itself.

In addition, ensure that you keep up to date on any security-related news or vulnerabilities with IBM Cloud Pak for AIOps by subscribing to security bulletins.

Security context constraints (SCC)

Administrators can use SCCs to control permissions for pods on their Red Hat OpenShift Container Platform cluster. These permissions include actions that a pod can perform and what resources it can access. Red Hat OpenShift Container Platform clusters contain default security context constraints (SCCs). IBM Cloud Pak for AIOps runs with the **`restricted`** or **`restricted-v2`** SCC that is included within this default set of constraints. For more information, see Red Hat® OpenShift® Container Platform SCCs and Red Hat - Managing Security Context Constraints.

Note: SecurityContextConstraints do not apply to the **`default`** or **`kube-system`** namespaces.

Permissions

For more information about the permissions that are required for Cloud Pak for AIOps, see Permissions.

Volume level encryption

You can configure Portworx encryption or host-level encryption, depending on your requirements. Decide which level of encryption is needed for each stateful data store in your environment.

- For more information about using encrypted volumes on Red Hat OpenShift Container Storage, see Creating a storage class for persistent volume encryption.
- For more information about using the encryption feature for Portworx volumes, see Create encrypted PVCs.

Security hardening

For production environments, ensure that the Red Hat OpenShift Container Platform cluster where you are installing IBM Cloud Pak for AIOps is configured securely. To help harden the security for your cluster, consider completing the following tasks:

- Configure the Red Hat OpenShift Container Platform to enable etcd data encryption. For more information, see the Red Hat documentation about Encrypting etcd data.
- Implement a network egress policy that strictly controls what outbound calls can be made from applications in the cluster and from the IBM Cloud Pak for AIOps project (namespace). For more information, see the Red Hat documentation about Creating a network policy.
- If you use your own certificate authority (CA), replace the default certificate manager CA with your own CA.
- Ensure that your Red Hat OpenShift Container Platform and Kubernetes environment is configured according to the Center for Internet Security (CIS) Benchmark for Red Hat Enterprise Linux based OpenShift V4 and Kubernetes V1.6 security hardening. For more information, see the Center for Internet Security (CIS) Benchmarks about Securing Kubernetes.
- Configure lockout mechanisms on your authentication server to handle excessive login attempts.
- Shorten session timeouts to the shortest tolerable duration.
- Use your own certificate authority and monitor certificate expiration dates.
- Configure rate limiting connections for basic protection against distributed denial-of-service (DDoS) attacks. For more information about how to configure this limiting, see the Red Hat documentation about Route configuration.
- Limit users from viewing information about other users. By default, user IDs, user groups, roles, and permissions for other users are visible to users. To block non-administrative users from viewing user groups, roles, and permissions,

    1. Edit the config map **`product-configmap`** to add the configuration **`usermgmt_limit_user_info: "true"`**.

2. Restart the user management pods, by running the following command:

```
oc delete pod -l component=usermgmt
```

Protecting against HTTP Host header attacks

The mandatory request header specifies the domain that you want to access can be altered as part of an exploitative attack. If your installation does not use a load balancer or proxy that depends on http **HOST** headers, then use the following steps to enable HTTP Host header injection protection:

1. Ensure that the HTTP Host header matches the value of **URL_PREFIX** from the ConfigMap **product-configmap**. If necessary, specify the project (namespace) of your Cloud Pak for AIOps deployment.
2. In configmap **product-configmap**, add or edit the **HOST_INJECTION_CHECK_ENABLED** entry and set its value to **true**. To set the entry by using the Red Hat OpenShift, select the **product-configmap** in your Cloud Pak for AIOps project (namespace). From the menu, select **Edit configmap**. On the YAML page, find or add the **HOST_INJECTION_CHECK_ENABLED** entry, and set the value to **true**.
3. Restart the **ibm-nginx-*** pods.
   - If you are using the Red Hat OpenShift console, select the pods and use the delete pod action.
   - If you are using the CLI, use the **oc delete <pod-name> -n <namespace>** command.

     Where **<namespace>** is the project (namespace) of your Cloud Pak for AIOps deployment.

If you need to disable this protection for any reason, remove the **HOST_INJECTION_CHECK_ENABLED** entry, or set its value to **false**, and restart the Nginx pods.

Certificates

If you want to use a custom certificate for IBM Cloud Pak for AIOps, then you can do this with either of the following methods:

- Configure a custom certificate for the Red Hat OpenShift cluster. Follow the instructions in the Red Hat OpenShift documentation Replacing the default ingress certificate. Then, deploy the signing CA certificate into the cluster by following the instructions in the Red Hat OpenShift documentation Replacing the CA Bundle certificate.
- If you would like to use a custom certificate for IBM Cloud Pak for AIOps, then after installation is complete follow the instructions in Using a custom certificate.

Image verification

You can optionally verify the IBM Cloud Pak for AIOps images before you install IBM Cloud Pak for AIOps. For more information, see Verifying images.

Verifying images

Use this information to verify the signatures on the IBM Cloud Pak® for AIOps images.

Digital signatures provide a way for consumers of content to ensure that what they download is authentic (it originated from the expected source) and has integrity (it is what it is expected to be). All images for IBM Cloud Pak for AIOps are signed.

Prerequisites

- Ensure that you these command line tools are installed (they can usually be installed on Linux® with the package manager):
  - GNU Privacy Guard v2 (package name **gpg2**)
  - OpenSSL (package name **openssl**)
  - skopeo
- The IBM Cloud Pak for AIOps public key must exist on the same machine as the command line tools. Copy the following text block exactly as shown into a text editor, and save it in a file named **cp4waiops-public.pub.asc**:

```

-----END PGP PUBLIC KEY BLOCK-----
```

- You must have a list of images to verify. To get a list of container images used in Cloud Pak for AIOps, refer to the procedure in Downloading or listing container images. In the following procedure, the example image *cp.icr.io/cp/cp4waiops/node-server:v3.7.0-00000000.0000-000000000* is used.

  Note: This tag is an example for demonstration purposes; it is not a real tag. Obtain the most up-to-date image names and tags with the procedure in Downloading or listing container images.

Procedure

1. Log in to the entitled registry `cp.icr.io` so that you can pull images from that registry.

   ```
   podman login cp.icr.io --username cp --password <entitlement_key>
   ```

   If you need to obtain the entitlement key that is assigned to your ID, complete the following steps:

   1. Log in to MyIBM Container Software Library with the IBMid and password that are associated with the entitled software.
   2. In the Entitlement keys section, select **Copy key** to copy the entitlement key to the clipboard.
2. Import the IBM Cloud Pak for AIOps public key on the machine that you prepared according to the Prerequisites section:

   ```
   sudo gpg2 --import cp4waiops-public.pub.asc
   ```

   Note: This step needs to be done only once on each machine you use for signature verification.

3. Calculate the fingerprint:

   ```
   fingerprint=$(sudo gpg2 --fingerprint --with-colons IBM Cloud Pak for AIOps | grep fpr | tr -d 'fpr:')
   ```

   This command stores the key's fingerprint in an environment variable called *fingerprint*, which is need for the command to verify the signature. When you exit your shell session, the variable is deleted. The next time that you log in to your machine, you can set it again by rerunning the command.

4. Create a directory for the image and use skopeo to pull it into local storage:

   ```
   mkdir images
   skopeo copy docker://cp.icr.io/cpopen/ibm-aiops-orchestrator:3.2.0-2021-00-00-0000-00000000 dir:$HOME/images
   ```

   This command downloads the image as a set of files and places them in the images directory (or another directory that you choose).

   Note: There is a manifest file named *images/manifest.json*, and a signature file named *images/signature-1*. You reference both these files in the next step (in the command to verify the signature).

5. Verify the signature:

   ```
   for SIGNATURE in $(ls $HOME/images | grep signature); do
       skopeo standalone-verify $HOME/images/manifest.json cp.icr.io/cp/cp4waiops/node-server:v3.7.0-00000000.0000-
   000000000 ${fingerprint} $HOME/images/$SIGNATURE 2> /dev/null
       if [ $? -eq 0 ]; then
          break
       fi
   done
   ```

   If the signature is verified, you get a confirmation similar to the following output. Otherwise, no output is provided:

   ```
   Signature verified, digest sha256:0000000000000000000000000000000000000000000000000000000000000000
   ```

Downloading or listing IBM Cloud Pak for AIOps images

You might need to download all of the container images for IBM Cloud Pak for AIOps, for example, to copy them to an internal registry, scan them for vulnerabilities, or verify their signatures. This procedure describes how to download container images, although you may need to use different tools, depending on your particular environment.

1. Follow the procedure in Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline) using a bastion host, up to and including the "Section 2 Download the CASE".

   These steps:

   - download the product CASE packages, which contain metadata for the container images required to deploy each capability. Each CASE package also contains the required scripts to mirror images to a private registry, and to configure the target cluster to use the private registry as a mirror.
   - generate comma-separated value (CSV) files listing the images for all capabilities (one CSV file is created for each capability and required dependencies). The CSV files, combined with your IBM Entitled Registry entitlement key, are used to download or mirror the images manually in the scripts below.

2. Log in to your container tool to access the entitled registry, using the username `cp` and your entitlement key.

3. Use a shell script to process all images from all capabilities supported on the target architecture.

   For example, for x86/amd64 architecture:

   ```
   tail -q -n +2 $HOME/offline/*-images.csv | while IFS="," read registry image_name tag digest mtype os arch variant
   insecure digest_source image_type groups; do
   if [[ "$arch" == "amd64" ]]; then
     podman pull "$registry/$image_name@$digest"
     podman tag "$registry/$image_name@$digest" "$registry/$image_name:$tag"
   fi
   done
   ```

   Instead of podman, you can use alternative container tools such as skopeo. Use one skopeocommand to replace the podman pull podman tag commands. For example:

   ```
   skopeo copy --dest-tls-verify=false docker://$registry/$image_name@$digest docker-daemon:$registry/$image_name:$tag
   ```

   You can also use skopeo to save images to disk, or to copy them directly to another container registry.

   Note: If you need your clusters to access these images from a private registry, the image digests must be preserved. If this is your intention, IBM recommends using the procedure in Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline).

Licensing

Review the following to learn about the licensing and entitlements for IBM Cloud Pak® for AIOps 4.8.0.

Notice: This License Guide is intended to provide only supplementary information to assist you in deploying the Programs you have licensed from IBM within your purchased entitlement. Your license agreement (such as the IBM International Program License Agreement (IPLA) or equivalent and its transaction documents, including the License Information for IBM Cloud Pak® for AIOps 4.8.0), is the sole and complete agreement between you and IBM regarding use of the Program.

- Viewing the license
- What's included in your purchaseof IBM Cloud Pak® for AIOps 4.8.0
- Red Hat Products
- Entitlement details
- License reporting

Viewing the license

To review the license agreement for IBM Cloud Pak® for AIOps 4.8.0 to find more information about licensing and entitlements for this offering, see L-BBAE-L53CM5.

What's included in your purchase of IBM Cloud Pak® for AIOps 4.8.0

Your purchase of IBM Cloud Pak for AIOps includes the following entitlements:

- Bundled Programs
- Supporting Programs
- Non-Production features
- Prohibited Components

Evaluation Period

The evaluation period starts upon agreement and lasts for 60 days.

Bundled Programs

As a licensee, you are authorized to install and use the followinig Bundled Programs:

- IBM Netcool Operations Insight Operations Management
- IBM Netcool Operations Insight Connection
- IBM Operations Analytics Predictive Insights
- IBM Robotic Process Automation Platform
- IBM Process Mining
- Monitoring

Supporting Programs

As a licensee, you are authorized to install and use the following supporting programs:

- IBM Netcool Operations Insight Agile Service Manager
- IBM Cloud Pak Foundational Services
- IBM Fusion
- IBM Cognos Analytics User Cartridge for IBM Cloud Pak for Data
- IBM Cognos Analytics Administrator Cartridge for IBM Cloud Pak for Data

Non-Production

As a licensee, the following components are limited for internal development and test environments for internal non-production activities ("Non-Production"):

- Story prioritization from persistence analysis and golden signals extraction
- Deploy to single ROSA cluster configured across multiple AWS Zones
- Multi-zone high availability and disaster recovery (HADR)
- IBM Cognos Analytics Integration for AIOps Custom Dashboards and Reporting

Prohibited Components

As a licensee, you are not authorized to use any of the following components or functions of the Program:

- Application Discovery component (of IBM Netcool Operations Insight Agile Service Manager)
- Network Discovery component (of IBM Netcool Operations Insight Agile Service Manager)
- Attended Bot Agent add-on (of IBM Robotic Process Automation)
- ABBYY FineReader OCR Provider (of IBM Robotic Process Automation)
- Business Process Model and Notation Export/Import Capability (of IBM Process Mining)
- Decision Model and Notation Export/Import Capability (of IBM Process Mining)

Red Hat Products

As a licensee, your purchase of IBM Cloud Pak® for AIOps 4.8.0 includes restricted entitlements for the following Red Hat products in the quantities and/or ratios set out in your license agreement:

- Red Hat OpenShift Container Platform

Entitlement details

Various metrics and conversion ratios apply to your entitlement of IBM Cloud Pak® for AIOps 4.8.0. These metrics and conversion ratios include, but not limited to, the following:

- Managed Client Device
- Managed Device
- Process
- Resource Unit
- Virtual Processor Core
- Virtual Server

The following table lists some of the entitlements per resource unit (perpetual) for IBM Cloud Pak for AIOps:

Table. Entitlement per resource units

Event Processing & Analytics	Metric Processing & Analytics	Log Processing & Analytics
- 1 Managed Device = 1 resource - 20 Client Devices = 1 resource - 10,000 Monthly Events = 7 resource	- 1 Managed Device = 1 resource - 20 Client Devices = 1 resource	• 50GB Monthly logs = 7 resource

License reporting

As part of using IBM Cloud Pak for AIOps, tracking your license usage is required. Although IBM Cloud Pak for AIOps provides license options not tracked directly by the product, to track usage, you must install and deploy the IBM Cloud Pak foundational services License Service on all clusters where IBM Cloud Pak for AIOps is installed.

IBM Cloud Pak foundational services License Service

This background License Service collects and stores the license usage information for tracking license consumption and for audit purposes. You can retrieve this data upon request for monitoring and compliance. You can also retrieve an audit snapshot of the data that is audit evidence.

Note: For IBM Cloud Pak for AIOps, the license service collects usage data for only IBM Cloud Pak for AIOps. Although IBM Cloud Pak for AIOps provides license options not tracked directly by the product, to track usage, you must deploy the IBM Cloud Pak for AIOps License Service on all clusters where IBM Cloud Pak for AIOps is installed.

Refer to the IBM Cloud Pak foundational services documentation to learn about how License Service collects and measures the license usage of IBM Cloud Pak for AIOps, and how to retrieve the license usage data.

- License Service
- License Service Reporter

Passport Advantage part numbers

You might need to download a package from IBM® Passport Advantage® to install some products and extensions for IBM Cloud Pak® for AIOps. This requirement can be due to your entitlement or based on how you choose to install the product or extension.

Use these tables to find the files for IBM Cloud Pak® for AIOps that are included in Passport Advantage and the corresponding part numbers.

- Downloading packages
- Quick start guide
- IBM Cloud Pak for AIOps Core packages
- IBM Cloud Pak for AIOps Supporting product packages

- Infrastructure Automation packages
- IBM Cloud Pak for AIOps Topology Manager product packages
- IBM Cloud Pak for AIOps Metrics Manager product packages
- IBM Cloud Pak for AIOps Extension eAssemblies

Downloading packages

Complete the following procedure to download your packages:

1. Go to the Passport Advantage Online tab at Passport Advantage and log in with your IBM ID.
2. Find your part number.
3. Search for your files by using the part numbers that are listed in the tables.
4. Download the files to a directory on your computer.

Core component eAssemblies

The following table lists the available multiplatform eAssembly number for IBM Cloud Pak for AIOps.

Table 1. Software eAssembly part numbers for base components

eAssembly #	Description
G0DB3EN	IBM Cloud Pak for AIOps 4.8.0 Installation Packages eAssembly

Quick start guide

The following table lists the quick start guide eImage number for IBM Cloud Pak for AIOps.

Table 1. Software eImage part number for quick start guide

eImage #	Description
M0NXBEN	IBM Cloud Pak for AIOps 4.8.0 Quick Start Guide

Supporting product eAssemblies

The following tables list the available eAssembly numbers for IBM Cloud Pak® for AIOps supporting products.

Table 2. Software eAssembly part numbers for supporting products

eAssembly #	Description
G0DCBML	IBM Robotic Process Automation for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCCML	IBM Process Mining for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCDML	IBM Netcool Operations Insight V1.6.13 Quick Start Guide for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCTML	IBM Netcool Operations Insight v1.6.13 Cloud Paks for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCVML	IBM Tivoli Netcool/OMNIbus v8.1 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCWML	IBM Tivoli Netcool Impact v7.1 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCXML	IBM Operations Analytics Log Analysis v1.3.8 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCYEN	IBM Operations Analytics Log Analysis Service Desk Extension v1.1 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DCZEN	IBM Operations Analytics Advanced Insights v1.3.6 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DD0ML	Jazz for Service Management 1.1.3.19 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DDGML	IBM Db2 Server Edition v11.5.x from Netcool Operations Insight V1.6.13 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DDHML	IBM Tivoli Monitoring for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DDJEN	IBM Tivoli Monitoring Agents for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DDLEN	IBM Tivoli Netcool/OMNIbus Probes for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DDMEN	IBM Tivoli Netcool/OMNIbus Probe Dependencies for IBM Cloud Pak for AIOps 4.8.0 eAssembly

G0DH9ML	ITCAM Transactions V7.4.0.1 Transaction Tracking for IBM Cloud Pak for AIOps 4.8.0 eAssembly

eAssembly #	Description
G0DHBML	IBM Rational 8.6 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DJ4ML	ITCAM for Microsoft Applications Version 6.3.1 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DJ5ML	ITCAM for Applications V7.2.2.2 for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DJ6ML	IBM Tivoli Monitoring for Virtual Environments V7.2.0.3 QSG for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DJ8ML	ITCAM for Application Diagnostics V7.1.0.4: Managing Server Component for IBM Cloud Pak for AIOps 4.8.0 eAssembly

Infrastructure Automation packages

The following table lists the eAssembly number for Infrastructure Automation - Infrastructure Management.

Table. Software eAssembly part numbers for Infrastructure Automation

eAssembly #	Description
G0DB2EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure Automation eAssembly

The following table lists the eImage numbers for Infrastructure Automation - Infrastructure Management.

Table. Software eImage part number for Infrastructure Automation

eImage #	Description
M0NX4EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure automation for VMware vSphere with PVSCSI controller
M0NX5EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure automation for Red Hat OpenStack Platform
M0NX6EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure automation for Amazon EC2
M0NX7EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure automation for Red Hat Virtualization
M0NX8EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure automation RPM updates
M0NX9EN	IBM Cloud Pak for AIOps 4.8.0 Infrastructure automation for Google Compute Engine

Topology Manager eAssemblies

Table 4. Software eAssembly part numbers for Topology Manager supporting products

eAssembly #	Description
G0DFYEN	IBM Netcool Agile Service Manager v1.1 Base for IBM Cloud Pak for AIOps 4.8.0 eAssembly
G0DFZEN	IBM Netcool Agile Service Manager v1.1 Observers for IBM Cloud Pak for AIOps 4.8.0 eAssembly

Metrics Manager eAssemblies

Table 5. Software eAssembly part numbers for Metrics Manager supporting products

eAssembly #	Description
G0DGTEN	IBM Operations Analytics Predictive Insights v1.3.6 for IBM Cloud Pak for AIOps 4.8.0 eAssembly

Supporting products and extensions

After you purchase an extension, follow these instructions to install your IBM Cloud Pak® for AIOps extension.

The part numbers for supporting products and extensions can be found in Passport Advantage part numbers.

Installing the Network Manager extension

You can integrate an on-premises IBM Netcool Network Management or IBM® Netcool® Operations Insight® - Network Management installation with IBM Cloud Pak for AIOps, while continuing to discover and manage physical and virtual network infrastructure.

To install the Network Manager extension, see Installing Network Management. To configure the IBM Cloud Pak for AIOps Network Manager observer to load data from the Network Manager extension into IBM Cloud Pak for AIOps, see Configuring Network Manager Observer jobs.

Installing IBM Cloud Pak for AIOps on OpenShift

You can choose to complete a standard production environment installation of IBM Cloud Pak® for AIOps, or a streamlined small starter installation for a non-production proof-of-concept or trial deployment.

Starter installation

A starter installation provides a concise installation of IBM Cloud Pak for AIOps for deployments that do not require a sustained workload. Use a starter installation only for proof-of-concept or experimentation environments.

- Online starter installation of IBM Cloud Pak for AIOps

Note: If you require an air-gapped (offline) deployment, you must complete a production installation.

Production installation

Production installations are intended for real world use cases and typically require more system and storage resources.

- Installing IBM Cloud Pak for AIOps (Production installation)

Online starter installation of IBM Cloud Pak for AIOps (CLI)

If you are a trial user of IBM Cloud Pak® for AIOps, or you want a proof-of-concept deployment that does not require a sustained workload, consider a starter installation to get a smaller, nonproduction deployment up and running quickly.

If you are installing on Azure Red Hat OpenShift (ARO), Google Cloud Platform (GCP), Red Hat® OpenShift® on IBM Cloud® service (ROKS), or Red Hat OpenShift Service on AWS (ROSA), then review the information in Installing on cloud platforms.

If you require a production-grade deployment, or an offline air-gapped deployment, see Installing IBM Cloud Pak for AIOps.

Before you begin

- You must know whether you are deploying a base deployment or a extended deployment of IBM Cloud Pak for AIOps. For more information, see Incremental adoption.
- Review the Planning section, and ensure that your cluster meets the system requirements for a starter deployment.
- Online installations of IBM Cloud Pak for AIOps can be run entirely as a non-root user, and do not require that user to have sudo access.
- Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).
- If you require details about the permissions that the IBM Cloud Pak for AIOps operators need, see Permissions (IBM Cloud Pak for AIOps).
- A user with `cluster-admin` privileges is needed for the following operations:
  - Create a custom project
  - Install Cert Manager
  - Install the License Service
  - Create the catalog sources
  - Create an OperatorGroup

Limitations

- After installation, you cannot increase the size of your IBM Cloud Pak for AIOps deployment from a starter deployment to a larger production deployment.
- High availability is not supported for starter deployments.
- This starter installation uses the `OwnNamespace` installation mode, which is the recommended installation mode for IBM Cloud Pak for AIOps, to provide better resilience and performance. For more information, see Operator installation mode.
- If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description

`icr.io`
`cp.icr.io`
`dd0.icr.io`
`dd2.icr.io`
`dd4.icr.io`
`dd6.icr.io`
	Allow access to these hosts on port 443 to enable access to the `IBM Cloud Container Registry` and IBM Cloud Pak® foundational services catalog source.

`dd1-icr.ibm-zh.com`
`dd3-icr.ibm-zh.com`
`dd5-icr.ibm-zh.com`
`dd7-icr.ibm-zh.com`
	If you are located in China, also allow access to these hosts on port 443.

`github.com`	Github houses IBM Cloud Pak tools and scripts.
`redhat.com`	Red Hat OpenShift registries that are required for Red Hat OpenShift, and for Red Hat OpenShift upgrades.

For more information, see Configuring your firewall for OpenShift Container Platform.

1. Install and configure Red Hat OpenShift Container Platform

IBM Cloud Pak for AIOps requires Red Hat OpenShift to be installed and running. You must have administrative access to your Red Hat OpenShift cluster.

For more information about the supported versions of Red Hat OpenShift, see Supported Red Hat OpenShift Container Platform versions.

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation.

2. Install the Red Hat OpenShift (**oc**) command-line interface (CLI) on your cluster's boot node and run **oc login**. For more information, see Getting started with the Red Hat OpenShift CLI.

3. Ensure that the clocks on your Red Hat OpenShift cluster are synchronized. Each Red Hat OpenShift node in the cluster must have access to an NTP server. Red Hat OpenShift nodes use NTP to synchronize their clocks. IBM Cloud Pak for AIOps runs on Red Hat OpenShift and also has this requirement. Discrepancies between the clocks on the Red Hat OpenShift nodes can cause IBM Cloud Pak for AIOps to experience operational issues. See the Red Hat OpenShift documentation for information about how to use a **MachineConfig** custom resource to configure chrony to connect to your NTP servers.

4. Optionally configure a custom certificate for IBM Cloud Pak for AIOps to use. You can use either of the following methods:

   - Configure a custom certificate for the Red Hat OpenShift cluster. Follow the instructions in the Red Hat OpenShift documentation Replacing the default ingress certificate. Then, deploy the signing CA certificate into the cluster by following the instructions in the Red Hat OpenShift documentation Replacing the CA Bundle certificate.
   - If you would like to use a custom certificate for IBM Cloud Pak for AIOps only, then after installation is complete follow the instructions in Using a custom certificate.

2. Configure storage

Configure your own storage for use with IBM Cloud Pak for AIOps. For more information, see Storage.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **RWX-storage-class-name** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

3. Create a custom project (namespace)

Create a project (namespace) called **cp4aiops** for your IBM Cloud Pak for AIOps deployment, by running the following command:

```
oc create namespace cp4aiops
```

4. Create an OperatorGroup in your custom project (namespace)

Create the Operator group by running the following command:

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: cp4aiops-operator-group
  namespace: cp4aiops
spec:
  targetNamespaces:
    - cp4aiops
EOF
```

5. Create the entitlement key pull secret

1. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.

2. In the *Entitlement keys* section, select **Copy** to copy your entitlement key to the clipboard.

3. From the Red Hat OpenShift CLI, run the following command:

   ```
   oc create secret docker-registry ibm-entitlement-key \
       --docker-username=cp \
       --docker-password=<entitlement-key> \
       --docker-server=cp.icr.io \
       --namespace=cp4aiops
   ```

   Where **<entitlement-key>** is the entitlement key that you copied in the previous step.

6. Configure usage data collection

To help the development of IBM Cloud Pak for AIOps, daily aggregated usage data is collected to analyse how IBM Cloud Pak for AIOps is used. The usage data is collected by the **cp4waiops-metricsprocessor** pod, and is sent to and stored in IBM controlled GDPR-compliant systems. The collection of usage data is enabled by default, but can be disabled. For transparency, the **cp4waiops-metricsprocessor** pod's logs contain all the information that is collected. The usage data that is collected is numeric, or is about the deployment type and platform. It does not include email addresses, passwords, or specific details. Only the following data is collected:

- Current number of applications
- Current number of alerts (all severities aggregated)
- Current number of incidents (all priorities aggregated)
- Current number of policies (includes predefined and user created)
- Current number of runbooks run since installation
- Current number of integrations of each type (For example ServiceNow, Instana, Falcon Logscale)
- Secure tunnel enablement: whether *connection* (which controls whether you can create a secure tunnel) is enabled in the *Installation* custom resource
- Deployment type: base deployment or extended deployment
- Deployment platform: Red Hat® OpenShift® Container Platform or Linux®

Configuring the collection of usage data

If you do not want to disable the collection of usage data, run the following steps.

1. Set environment variables.

```
export CUSTOMER_NAME=<your company name>
export CUSTOMER_ICN=<your IBM Customer Number>
export CUSTOMER_ENVIRONMENT=<Set to `trial` or `poc`>
export PROJECT_CP4AIOPS=cp4aiops
```

2. Configure the usage data with your customer details.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME}
--from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT}
```

3. If you have a firewall enabled, ensure that outbound traffic to https://api.segment.io is allowed.

Important: Usage data without your customer details is still collected even if you do not create this secret. If you do not want any usage data collected, then you must run the command given in *Disabling the collection of usage data*.

Disabling the collection of usage data

If you want to disable the collection of usage data, run the following commands.

1. Set environment variables.

```
export CUSTOMER_NAME=<your company name>
export CUSTOMER_ICN=<your IBM Customer Number>
export CUSTOMER_ENVIRONMENT=<Set to `trial` or `poc`>
export PROJECT_CP4AIOPS=cp4aiops
```

2. Disable usage data collection

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME}
--from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT} --from-
literal=enableCollection=false
```

Note: You can update your usage data collection preferences after installation. For more information, see Updating usage data collection preferences.

7. Create the catalog sources

1. Run the following command to create the catalog sources for IBM Cloud Pak for AIOps and IBM Cloud Pak® foundational services Cert Manager and License Service in the *openshift-marketplace* namespace.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-aiops-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-aiops-catalog
  publisher: IBM Content
  sourceType: grpc
  image: icr.io/cpopen/ibm-aiops-catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cert-manager-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cert-manager
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-cert-manager-operator-catalog
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-licensing-catalog
  namespace: openshift-marketplace
spec:
  displayName: IBM License Service Catalog
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-licensing-catalog
EOF
```

2. Verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* `CatalogSource` objects are in the output that is returned by the following command:

```
oc get CatalogSources -n openshift-marketplace
```

Example output:

```
oc get CatalogSources -n openshift-marketplace
NAME                    DISPLAY                     TYPE   PUBLISHER   AGE
```

```
ibm-aiops-catalog        ibm-aiops-catalog            grpc   IBM          2m
ibm-cert-manager-catalog ibm-cert-manager             grpc   IBM          2m
ibm-licensing-catalog    IBM License Service Catalog  grpc   IBM          2m
```

8. Install Cert Manager

Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

1. Run the following command to create the resource definitions that you need:

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Namespace
metadata:
  name: ibm-cert-manager
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-cert-manager-operator-group
  namespace: ibm-cert-manager
---
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-cert-manager-operator
  namespace: ibm-cert-manager
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-cert-manager-operator
  source: ibm-cert-manager-catalog
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

```
oc -n ibm-cert-manager get pods
```

Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-cainjector-674854c49d-vstq4   1/1     Running   0          8d
cert-manager-controller-646d4bd6fd-zwmqm   1/1     Running   0          8d
cert-manager-webhook-8598787c8-s41kt       1/1     Running   0          8d
ibm-cert-manager-operator-c96957695-dkxnm  1/1     Running   0          8d
```

9. Install the License Service

Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

1. Run the following command to create the resource definitions that you need:

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Namespace
metadata:
  name: ibm-licensing
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-licensing-operator-group
  namespace: ibm-licensing
spec:
  targetNamespaces:
  - ibm-licensing
---
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-licensing-operator-app
  namespace: ibm-licensing
```

```
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-licensing-operator-app
  source: ibm-licensing-catalog
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-licensing get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services License Service installation:

   ```
   NAME                                                READY   STATUS    RESTARTS   AGE
   ibm-licensing-operator-db4cd746c-xzmlf              1/1     Running   0          8d
   ibm-licensing-service-instance-596b99588f-76cc5     1/1     Running   0          8d
   ```

For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

10. Verify cluster readiness

Run the prerequisite checker script to verify whether your Red Hat OpenShift cluster is correctly set up for an IBM Cloud Pak for AIOps installation.

Download the prerequisite checker script from github.com/IBM, and run it with the following command:

```
./prereq.sh -n cp4aiops
```

Example output:

```
# ./prereq.sh -n cp4aiops

[INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

```

11. Install the IBM Cloud Pak for AIOps operator

For more information about the operators which are installed with IBM Cloud Pak for AIOps, see Operator Details.

Run the following command:

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-aiops-orchestrator
  namespace: cp4aiops
spec:
  channel: v4.8
  installPlanApproval: Automatic
  name: ibm-aiops-orchestrator
  source: ibm-aiops-catalog
  sourceNamespace: openshift-marketplace
EOF
```

Warning: installPlanApproval must not be changed to *Manual*. Manual approval, which requires the manual review and approval of the generated InstallPlans, is not supported. Incorrect timing or ordering of manual approvals of InstallPlans can result in a failed installation.

After a few minutes, the IBM Cloud Pak for AIOps operator is installed. Verify that the all of the components have a state of **Succeeded** by running the following command:

```
oc get csv -n cp4aiops | egrep "ibm-aiops-orchestrator"
```

Example output:

```
$ oc get csv -n cp4aiops | egrep "ibm-aiops-orchestrator"
ibm-aiops-orchestrator.v4.8.0         IBM Cloud Pak for AIOps               4.8.0   Succeeded
```

12. Install IBM Cloud Pak for AIOps

Note: A maximum of one IBM Cloud Pak for AIOps custom resource is allowed per cluster.

Run the following command to create an instance of the IBM Cloud Pak for AIOps custom resource called **ibm-cp-aiops**.

Warning: The pakModules **aiopsFoundation**, **applicationManager**, and **aiManager** must be enabled as in the following YAML. Do not change these values to false.

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ibm-cp-aiops
  namespace: cp4aiops
spec:
  imagePullSecret: ibm-entitlement-key
  license:
    accept: <license_acceptance>
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: false
  - name: logAnomalyDetection
    enabled: <enable_log_anomaly_detection>
  size: small
  storageClass: <storage_class_name>
  storageClassLargeBlock: <large_block_storage_class_name>
  topologyModel: application
EOF
```

Where

- **<license_acceptance>** - is set to *true* to agree to the license terms.
- **<enable_log_anomaly_detection>** - set to *true* to install an extended deployment with log anomaly detection and ticket analysis capabilities enabled. Set to *false* to install a base deployment without log anomaly detection and ticket analysis capabilities enabled. For more information, see Incremental adoption.
- **<storage_class_name>** and **<large_block_storage_class_name>** are the storage classes that you want to use, as detailed in the following table. For more information about storage, see Storage.

Note: To confirm that you have the storage classes for your chosen storage provider as shown in the table, run **oc get sc**.

Table 1. Storage provider classes

Storage provider	storage_class_name	large_block_storage_class_name
IBM Cloud®	ibmc-block-gold	ibmc-block-gold
IBM Cloud® with OADP backup and restore	ibmc-file-gold-gid	ibmc-block-gold
Red Hat® OpenShift® Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
Red Hat® OpenShift® Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Global Data Platform	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc
IBM Storage Scale Container Native	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc
Portworx	px-csi-aiops	px-csi-aiops
Portworx (multi-zone HA)	px-csi-aiops-mz	px-csi-aiops-mz
AWS native storage	gp3-csi	gp3-csi
AWS native storage with OADP backup and restore	efs-sc	gp3-csi

13. Verify your installation

Run the following command to check that the **PHASE** of your installation is **Updating**.

```
oc get installations.orchestrator.aiops.ibm.com -n cp4aiops
```

Example output:

```
NAME            PHASE      LICENSE    STORAGECLASS    STORAGECLASSLARGEBLOCK    AGE
ibm-cp-aiops    Updating   Accepted   rook-cephfs     rook-ceph-block           3m
```

It takes around 60-90 minutes for the installation to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **PHASE** of your installation changes to **Running**. If your installation phase does not change to **Running**, then use the following command to find out which components are not ready:

```
oc get installation.orchestrator.aiops.ibm.com -o yaml -n cp4aiops | grep 'Not Ready'
```

Example output:

```
lifecycleservice: Not Ready
zenservice: Not Ready
```

To see details about why a component is **Not Ready** run the following command, where **<component>** is the component that is not ready, for example **zenservice**.

```
oc get <component> -o yaml -n cp4aiops
```

(Optional) You can also download and run a status checker script to see information about the status of your deployment. For more information about how to download and run the script, see github.com/IBM.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

14. Log in to the IBM Cloud Pak for AIOps console

1. Find the password for the **admin** username by running the following command:

   ```
   oc -n cp4aiops get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d
   ```

2. Find the URL to access the IBM Cloud Pak for AIOps console with the following command.

   ```
   oc get route -n cp4aiops cpd -o jsonpath='{.spec.host}'
   ```

   The following output is a sample output:

   ```
   cpd-cp4aiops.apps.mycluster.mydomain
   ```

Based on the sample output, your console URL would be **`https://cpd-cp4aiops.apps.mycluster.mydomain`**

3. Enter the URL in your browser to open the IBM Cloud Pak for AIOps console and log in with a username of **`cpadmin`** and the password that you found in the previous step.

What to do next

- Define integrations and applications with Defining.
- You can integrate with IBM Cognos® Analytics. For more information, see Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.

Installing IBM Cloud Pak for AIOps (Production installation)

Depending on whether your OpenShift cluster is connected to the internet, choose either an online or an offline installation.

If you are installing on Azure Red Hat OpenShift (ARO), Google Cloud Platform (GCP), Red Hat® OpenShift® on IBM Cloud® service (ROKS), Red Hat OpenShift Service on AWS (ROSA), or AWS GovCloud, then review the information in Installing on cloud platforms.

Online installation

If your cluster is connected to the internet, then you can install IBM Cloud Pak® for AIOps using the Red Hat® OpenShift® Container Platform console or the command line interface (CLI). Choose one of the following topics.

- Online production installation of IBM Cloud Pak for AIOps (console method)
- Online production installation of IBM Cloud Pak for AIOps (CLI method)

Offline installation

If your Red Hat OpenShift cluster is not connected to the internet, then you can perform an airgapped (offline) installation.

- Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline)

Online production installation of IBM Cloud Pak for AIOps (console method)

If your cluster is connected to the internet, you can complete a production installation of IBM Cloud Pak® for AIOps with the Red Hat® OpenShift® Container Platform console.

Before you begin

- You must know whether you are deploying a base deployment or a extended deployment of IBM Cloud Pak for AIOps. For more information, see Incremental adoption.
- Review the Planning section.
- Online installations of IBM Cloud Pak for AIOps can be run entirely as a non-root user, and do not require that user to have sudo access.
- Some steps must still be run with the command line. Ensure that you are logged in to your Red Hat OpenShift cluster with **`oc login`** for any steps that use the Red Hat OpenShift command-line interface (CLI).
- The display names of some Red Hat OpenShift console components, such as window titles and push buttons, vary between Red Hat OpenShift versions. The following instructions are based on Red Hat OpenShift version 4.14 console components.
- If you require details about the permissions that the IBM Cloud Pak for AIOps operators need, see Permissions (IBM Cloud Pak for AIOps).
- A user with **`cluster-admin`** privileges is needed for the following operations:
  - Create a custom project
  - Create the catalog sources
  - Install Cert Manager
  - Install the License Service
  - Install the operator

Important: If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

Installation procedure

Follow these steps to install IBM Cloud Pak for AIOps.

1. Install and configure Red Hat OpenShift
2. Configure storage

3. Create a custom project (namespace)
4. Create the entitlement key secret
5. Configure usage data collection
6. Create the catalog sources
7. Install Cert Manager
8. Install the License Service
9. Verify cluster readiness
10. Install the operator
11. Install IBM Cloud Pak for AIOps
12. Verify your installation
13. Create an EgressFirewall to restrict outgoing traffic
14. Access the IBM Cloud Pak for AIOps console

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description

`icr.io`
`cp.icr.io`
`dd0.icr.io`
`dd2.icr.io`
`dd4.icr.io`
`dd6.icr.io`
	Allow access to these hosts on port 443 to enable access to the **`IBM Cloud Container Registry`** and IBM Cloud Pak® foundational services catalog source.

`dd1-icr.ibm-zh.com`
`dd3-icr.ibm-zh.com`
`dd5-icr.ibm-zh.com`
`dd7-icr.ibm-zh.com`
	If you are located in China, also allow access to these hosts on port 443.

`github.com`	Github houses IBM Cloud Pak tools and scripts.
`redhat.com`	Red Hat OpenShift registries that are required for Red Hat OpenShift, and for Red Hat OpenShift upgrades.

For more information, see Configuring your firewall for OpenShift Container Platform.

1. Install and configure Red Hat OpenShift

IBM Cloud Pak for AIOps requires Red Hat OpenShift to be installed and running. You must have administrative access to your Red Hat OpenShift cluster.

For more information about supported versions of Red Hat OpenShift, see Supported Red Hat OpenShift Container Platform versions.

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation.
2. Install the Red Hat OpenShift command line interface (**`oc`**) on your cluster's boot node and run **`oc login`**. For more information, see the instructions in Getting started with the Red Hat OpenShift CLI.
3. Ensure that the clocks on your Red Hat OpenShift cluster are synchronized. Each Red Hat OpenShift node in the cluster must have access to an NTP server. Red Hat OpenShift nodes use NTP to synchronize their clocks. IBM Cloud Pak for AIOps runs on Red Hat OpenShift and also has this requirement. Discrepancies between the clocks on the Red Hat OpenShift nodes can cause IBM Cloud Pak for AIOps to experience operational issues. See the Red Hat OpenShift documentation for information about how to use a **`MachineConfig`** custom resource to configure chrony to connect to your NTP servers.
4. Optionally configure a custom certificate for IBM Cloud Pak for AIOps to use. You can use either of the following methods:
   - Configure a custom certificate for the Red Hat OpenShift cluster. Follow the instructions in the Red Hat OpenShift documentation Replacing the default ingress certificate. Then, deploy the signing CA certificate into the cluster by following the instructions in the Red Hat OpenShift documentation Replacing the CA Bundle certificate.
   - If you would like to use a custom certificate for IBM Cloud Pak for AIOps only, then after installation is complete follow the instructions in Using a custom certificate.

2. Configure storage

The storage configuration must satisfy your sizing requirements. For more information about the storage classes that are needed for installing IBM Cloud Pak for AIOps, see Storage.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **`RWX-storage-class-name`** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

3. Create a custom project (namespace)

Create a project (namespace) to deploy IBM Cloud Pak for AIOps into.

A project is a Kubernetes namespace. You must create a custom project (namespace) and not use the **`default`**, **`kube-system`**, **`kube-public`**, **`openshift-node`**, **`openshift-infra`**, or **`openshift`** projects (namespaces). This is because IBM Cloud Pak for AIOps uses Security Context Constraints (SCC), and SCCs cannot be assigned to pods created in one of the default Red Hat OpenShift projects (namespaces).

1. From your Red Hat OpenShift console, click **Home** > **Projects**.
2. Select **Create Project**, specify the **Name** of the project that you want to create, for example *cp4aiops* and click **Create**.

4. Create the entitlement key secret

Complete the following steps to create a registry secret to enable your deployment to pull the IBM Cloud Pak for AIOps images from the IBM® Entitled Registry.

1. Obtain the entitlement key that is assigned to your IBMid. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
2. In the *Active entitlement keys* section, select **Copy** to copy the entitlement key to the clipboard.
3. From your Red Hat OpenShift console, click **Workloads** > **Secrets**.
4. From the **Project** menu, select the project that you created earlier in Create a custom project (namespace).
5. Click the **Create** button, and select **Image pull secret** from the menu. The **Create image pull secret** form is displayed. Enter the following values and then click **Create**.
   - **Secret name**: `ibm-entitlement-key`
   - **Authentication type**: `Image registry credentials`
   - **Registry server address**: `cp.icr.io`
   - **Username**: `cp`
   - **Password**: use the entitlement key that you copied in step 2.

5. Configure usage data collection

To help the development of IBM Cloud Pak for AIOps, daily aggregated usage data is collected to analyse how IBM Cloud Pak for AIOps is used. The usage data is collected by the `cp4waiops-metricsprocessor` pod, and is sent to and stored in IBM controlled GDPR-compliant systems. The collection of usage data is enabled by default, but can be disabled. For transparency, the `cp4waiops-metricsprocessor` pod's logs contain all the information that is collected. The usage data that is collected is numeric, or is about the deployment type and platform. It does not include email addresses, passwords, or specific details. Only the following data is collected:

- Current number of applications
- Current number of alerts (all severities aggregated)
- Current number of incidents (all priorities aggregated)
- Current number of policies (includes predefined and user created)
- Current number of runbooks run since installation
- Current number of integrations of each type (For example ServiceNow, Instana, Falcon Logscale)
- Secure tunnel enablement: whether *connection* (which controls whether you can create a secure tunnel) is enabled in the *Installation* custom resource
- Deployment type: base deployment or extended deployment
- Deployment platform: Red Hat® OpenShift® Container Platform or Linux®

Use the following steps to configure or disable usage data collection.

1. From your Red Hat OpenShift console, click **Workloads** > **Secrets**.
2. From the **Project** menu, select the project that you created earlier in Create a custom project (namespace).
3. Click the **Create** button, and select **Key/value secret** from the menu. The **Create key/value secret** form is displayed. Enter the following values and then click **Create**.
   - **Secret name**: `aiops-metrics-processor`
   - Add the following **Key**/**Value** pairs:
     - **customerName**: your company name
     - **customerICN**: your IBM Customer Number (ICN)
     - **environment**: `trial` for testing, `poc` for proof of concept, or `production` for production environments.
   - If you want to disable usage data collection, also add the following key/value pair: **enableCollection**: false
4. If you have a firewall enabled, ensure that outbound traffic to https://api.segment.io is allowed.

Important: Usage data without your customer details is still collected even if you do not create this secret. If you do not want any usage data collected, then you must create this secret with **enableCollection** set to false.

You can update your usage data collection preferences after installation. For more information, see Updating usage data collection preferences.

6. Create the catalog sources

1. Run the following command to create the catalog sources for IBM Cloud Pak for AIOps and IBM Cloud Pak® foundational services Cert Manager and License Service in the *openshift-marketplace* namespace.

   Log in to your Red Hat OpenShift cluster's console. Click the plus icon in the upper right to open the **Import YAML** dialog box, paste in the following YAML, and then click **Create**.

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-aiops-catalog
  namespace: openshift-marketplace
spec:
```

```
  displayName: ibm-aiops-catalog
  publisher: IBM Content
  sourceType: grpc
  image: icr.io/cpopen/ibm-aiops-catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cert-manager-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cert-manager
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-cert-manager-operator-catalog
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-licensing-catalog
  namespace: openshift-marketplace
spec:
  displayName: IBM License Service Catalog
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-licensing-catalog
```

2. Go to **Administration** > **Cluster Settings**. Under **Configuration** > **OperatorHub** > **Sources**, verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* `CatalogSource` objects are present.

7. Install Cert Manager

Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

1. Log in to your Red Hat OpenShift cluster's console.
2. Click **Operators** > **OperatorHub**. The **OperatorHub** page is displayed.
3. In the **All Items** field, enter `IBM Cert Manager`. The **IBM Cert Manager** operator is displayed.
4. Click the **IBM Cert Manager** tile. The **IBM Cert Manager** window is displayed.
5. Click **Install**. You see the **Install Operator** page.
6. Set the **Update Channel** to the `v4.2` version. If the Channel `v4.2` version is not available, click other **IBM Cert Manager** tile from OperatorHub to install the correct version.
7. Set **Installation Mode** to `All namespaces on the cluster (default)`.
8. Set **Installed Namespace** to `ibm-cert-manager(Operator recommended)`.
9. Set **Update approval** to `Automatic`.
10. Click **Install**.

8. Install the License Service

Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not know whether the License Service is already installed, then see Verifying if License Service is already installed on the cluster in the IBM Cloud Pak foundational services documentation.

IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

Follow the instructions in Installing the License Service with OpenShift console in the IBM Cloud Pak foundational services documentation, from step 2 `Create the ibm-licensing namespace` onwards.

9. Verify cluster readiness

Run the prerequisite checker script to verify whether your Red Hat OpenShift cluster is correctly set up for a IBM Cloud Pak for AIOps installation.

Download the prerequisite checker script from github.com/IBM, and run it with the following command:

```
./prereq.sh -n <project>
```

Where `<project>` is the project that your IBM Cloud Pak for AIOps installation is deployed in.

Important: If you are installing on a multi-zone cluster, then also specify the `-m` flag to assess whether there are sufficient resources to withstand a zone outage.

Example output:

```
# ./prereq.sh -n cp4aiops

[INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

```

10. Install the operator

For more information about installing operators, see Adding Operators to a cluster in the Red Hat OpenShift documentation.

For more information about the operators which are installed with IBM Cloud Pak for AIOps, see Operator Details.

Note: During the initial installation of Cloud Pak for AIOps, Kubernetes jobs might fail and re-run. If a job succeeds on the second or third attempt, there can be one or two pods in `Error` state and one pod in the `Completed` state. If a job fails repeatedly, the attempt is abandoned, and the logs from failed pods can be used to determine the cause of the failure. When you determine the cause for the failure, you can delete the job, and the operator can recreate it to reattempt the operations.

1. Log in to your Red Hat OpenShift cluster's console.
2. Click **Operators** > **OperatorHub**. The **OperatorHub** page is displayed.

3. In the **All Items** field, enter `IBM Cloud Pak for AIOps`. The **IBM Cloud Pak for AIOps** operator is displayed.
4. Click the **IBM Cloud Pak for AIOps** tile with the CatalogSource tag *ibm-aiops-catalog*. The **IBM Cloud Pak for AIOps** window is displayed.
5. Click **Install**. The **Install Operator** page is displayed.
6. Enter the following values:
   - Set **Update channel** to *v4.8*.
   - **Installation mode** - For more information about installation modes, see Operator installation mode.
   - **Installed Namespace** - If you are using the `OwnNamespace` installation mode (a specific namespace), then set this field to be the project (namespace) in which to install the operator, such as `cp4aiops`. If you are using the `AllNamespaces` installation mode, then set this field to `openshift-operators`.
   - Set **Update approval** to *Automatic*. This must not be changed to *Manual*. Manual approval, which requires the manual review and approval of the generated InstallPlans, is not supported. Incorrect timing or ordering of manual approvals of InstallPlans can result in a failed installation.
7. Click **Install** and wait for the IBM Cloud Pak for AIOps operator to install.
8. Verify that the IBM Cloud Pak for AIOps operator is successfully installed.

   Navigate to **Operators** > **Installed Operators**, and select your project from the **Projects** dropdown. **IBM Cloud Pak for AIOps** and its dependant operators in the project are listed with a **Status** of *Succeeded*.

11. Install IBM Cloud Pak for AIOps

Create an instance of the IBM Cloud Pak for AIOps custom resource. A maximum of one IBM Cloud Pak for AIOps custom resource is allowed per cluster.

1. From your Red Hat OpenShift console, click **Operators** > **Installed Operators**.
2. From the **Project** dropdown menu, select the project that you want to create the IBM Cloud Pak for AIOps instance in. Use the project that you created earlier in Create a custom project (namespace).

   Note: You cannot use the `default`, `kube-system`, `kube-public`, `openshift-node`, `openshift-infra`, or `openshift` projects. This is because IBM Cloud Pak for AIOps uses Security Context Constraints (SCC), and SCCs cannot be assigned to pods created in one of the default Red Hat OpenShift projects.
3. Select **IBM Cloud Pak for AIOps** operator, then click the **IBM Cloud Pak for AIOps** tab.
4. Click **Create Installation**. The default **Form View** is displayed.

   Warning: The pakModules `aiopsFoundation`, `applicationManager`, and `aiManager` must be enabled. Do not change these values to false.

   Enter the following values:
   - **Name**: Specify the name that you want your IBM Cloud Pak for AIOps instance to be called, for example `ibm-cp-aiops`.
   - **license**: Expand the **license** section and read the agreement. Toggle the **License Acceptance** switch to **true** to accept the license.
   - **File Storage Class** and **Large Block Storage Class** are the storage classes that you want to use, as detailed in the following table. For more information about storage, see Storage.
   - **Enable Secure Tunnel**: Set to true if you want to install Secure Tunnel. For more information about Secure Tunnel, see Secure Tunnel.
   - **Image Pull Secret**: Select the `ibm-entitlement-key` secret that you created in the step Create the entitlement key secret.
   - **Resource Overrides ConfigMap** Do not edit this field unless you have been supplied with a custom `ConfigMap` by an IBM Sales representative (or Business Partner).
   - **Size**: Select the size that you require for your IBM Cloud Pak for AIOps installation.
   - **Topology resource group terminology**: Specify `application` or `service` as the terminology to be used for collections of topology resource groups. The default is `application`.
   - **Zones**: If you are installing on a multi-zone cluster, then add the names of the zones that you are using. The zone names must exactly match the zone labels that you applied to each of your nodes in step 1a of Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA).

     Note: To confirm that you have the storage classes for your chosen storage provider as shown in the table, run `oc get sc`.

Table 1. Storage provider classes

Storage provider	File Storage Class	Large Block Storage Class
IBM Cloud®	ibmc-block-gold	ibmc-block-gold
IBM Cloud® with OADP backup and restore	ibmc-file-gold-gid	ibmc-block-gold
Red Hat® OpenShift® Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
Red Hat® OpenShift® Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Global Data Platform	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc

Storage provider	File Storage Class	Large Block Storage Class
IBM Storage Scale Container Native	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc
Portworx	px-csi-aiops	px-csi-aiops
Portworx (multi-zone HA)	px-csi-aiops-mz	px-csi-aiops-mz
AWS native storage	gp3-csi	gp3-csi
AWS native storage with OADP backup and restore	efs-sc	gp3-csi

5. Configure your deployment to be a base deployment or an extended deployment.

   For more information about these deployment types, see Incremental adoption.

   Your deployment defaults to a base deployment which does not have log anomaly detection and ticket analysis capabilites. If you want a base deployment, then proceed to the next step.

   If you want an extended deployment with log anomaly detection and ticket analysis capabilites, then switch to the **YAML** view and set the value of **enabled** to **`true`**.

   Example excerpt:

   ```
   spec:
     pakModules:
     - enabled: true
       name: logAnomalyDetection
   ```

   You can update your deployment type after installation. For more information, see Updating the deployment type.

6. Click **Create** to create a custom resource that is an instance of IBM Cloud Pak for AIOps.

12. Verify your installation

1. After a few minutes, use the following steps to check the status of your installation. Click **Operators** > **Installed Operators**.
2. From the **Project** list, select the project (namespace) that IBM Cloud Pak for AIOps is deployed in.
3. Select **IBM Cloud Pak for AIOps** and then click the **IBM Cloud Pak for AIOps** tab.
4. Under **Installations**, look for the entry with the name that you specified for your IBM Cloud Pak for AIOps instance, and verify that it has a **Status** of *Phase: Updating*. It takes around 60-90 minutes for the installation to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **Status** changes to *Phase: Running*.
5. (Optional) If you want to see more detail about the status of the installation's components, select the entry with the name that you specified for your IBM Cloud Pak for AIOps instance, and then switch to the **YAML** view. Scroll down to the **Status** section near the end of the YAML. A component's installation is complete and successful when the component has a value of **`Ready`**.

   Example YAML:

   ```
   status:
     size: small
     customProfileConfigmap: aiops-custom-size-profile
     customProfileValidationStatus: >-
       Custom profile configmap not found, continue installation process without customization
     storageclasslargeblock: rook-ceph-rbd
     componentstatus:
       issueresolutioncore: Ready
       kafka: Ready
       aiopsanalyticsorchestrator: Ready
       aiopsedge: Ready
       tunnel: Ready
       lifecycleservice: Ready
       zenservice: Ready
       flinkcluster: Ready
       cluster: Ready
       elasticsearchcluster: Ready
       aiopsui: Ready
       redissentinel: Ready
       <...>
   ```

(Optional) You can also download and run a status checker script to see information about the status of your deployment. For more information about how to download and run the script, see github.com/IBM.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems

13. Create an EgressFirewall

There is no egress firewall policy defined when you install IBM Cloud Pak for AIOps, so outgoing traffic from workload pods to the internal and external network is unrestricted.

To create a more secure environment, use the following steps.

1. Create an **`EgressFirewall`** on your Red Hat OpenShift cluster to limit egress from the IBM Cloud Pak for AIOps project (namespace).

   For more information about creating an **`EgressFirewall`**, see Configuring an egress firewall for a project.

   Note: You can only have one **`EgressFirewall`** per project/namespace.

2. Configure exceptions to the **`EgressFirewall`**.

   Edit your **`EgressFirewall`** to add exceptions for the following IBM Cloud Pak for AIOps components that have egress dependencies, otherwise these IBM Cloud Pak for AIOps components fail when they attempt egress.

   1. Allow egress to any external services, such as the following integrations:
      - Kubernetes
      - GitHub
      - Microsoft® Teams
      - ServiceNow
      - Slack
      - VMware® vCenter
   2. Configure your **`EgressFirewall`** to allow traffic for your GitHub, Kubernetes, ServiceNow, and VMware vCenter integrations.

      Edit your **`EgressFirewall`** to allow or deny egress, as in the following example:

```
kind: EgressFirewall
metadata:
  name: default
spec:
  egress:
  - type: Allow
    to:
      cidrSelector: <1.2.3.0/24>
  - type: Allow
    to:
      dnsName: <www.github.com>
  - type: Allow
    to:
      dnsName: <www.developer.kubernetes.com>
  - type: Allow
    to:
      dnsName: <www.developer.servicenow.com>
  - type: Allow
    to:
      dnsName: <www.developer.vcenter.com>
  - type: Deny
    to:
      cidrSelector: <0.0.0.0/0>
```

      Where the values you enter for **`dnsName`** and **`cidrSelector`** are the DNS names and addresses of your GitHub, Kubernetes, ServiceNow, or VMware vCenter sources.

14. Access the IBM Cloud Pak for AIOps UI

After you successfully install IBM Cloud Pak for AIOps, you can use the IBM Cloud Pak Administration panel to manage the underlying deployment, or use the IBM Cloud Pak for AIOps console to use IBM Cloud Pak for AIOps.

IBM Cloud Pak Administration panel

You can use the **Launch Admin Hub** link to access the IBM Cloud Pak Administration panel:

1. Log in to the Red Hat OpenShift Container Platform web console as an administrator.
2. Click **Operators** > **Installed Operators**.
3. Click **IBM Cloud Pak for AIOps**.
4. On the *Operator Details* page, click the **IBM Cloud Pak for AIOps** tab, and then click the IBM Cloud Pak for AIOps installation name.
5. In the Details tab, right-click on the URL underneath **Launch Admin Hub**, and select **Open Link in New Tab**.
6. On the IBM Cloud Pak Administration panel login page, select one of the following login options:
   - **OpenShift authentication**: The **`kubeadmin`** user is automatically used to log in to the Administration panel. The **`kubeadmin`** user has the same privileges as the Administration panel admin user.
   - **IBM provided credentials (admin only)**: The default username to access the console is **`admin`**. To obtain the username and password, see Obtain IBM provided credentials (admin only).

Cloud Pak for AIOps console

You can use the **Launch Cloud Pak in IBM Automation** link to access the Cloud Pak for AIOps console:

1. Log in to the Red Hat OpenShift Container Platform web console as an administrator.
2. Click **Operators** > **Installed Operators**.
3. Click **IBM Cloud Pak for AIOps**.

4. On the *Operator Details* page, click the **IBM Cloud Pak for AIOps** tab, and then click the IBM Cloud Pak for AIOps installation name.
5. In the **Details** tab, right-click on the URL underneath **Launch Cloud Pak in IBM Automation**, and select **Open Link in New Tab**.
6. In the Cloud Pak for AIOps console login page, select one of the following login options:
   - **OpenShift authentication**: The `kubeadmin` user is automatically used to log in to the Cloud Pak for AIOps console. The `kubeadmin` user has the same privileges as the Cloud Pak for AIOps console admin user.
   - **IBM provided credentials (admin only)**: The default username to access the console is `admin`. To obtain the username and password, see Obtain IBM provided credentials (admin only).
   - **Enterprise LDAP**: LDAP users can log in to the Cloud Pak for AIOps console after IBM Cloud Pak for AIOps is configured with a single or multiple LDAP servers for the authentication and authorization. For more information, see Identity Management (IM).

Obtain IBM provided credentials (admin only)

1. To find the default username, run the following command:

   ```
   oc -n <project> get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_username}' | base64 -d && echo
   ```

   Where `<project>` is the project (namespace) that IBM Cloud Pak for AIOps is deployed in.

2. To get the password for the *admin* username, run the following command:

   ```
   oc -n <project> get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d
   ```

   Where `<project>` is the project (namespace) that IBM Cloud Pak for AIOps is deployed in.

   The following is a sample output:

   ```
   EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA
   ```

   Based on the sample output, your password would be `EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA`.

   Important: You can change this default password at any time. For more information, see Changing the cluster administrator password.

What to do next

- Define integrations and applications with Defining.
- You can integrate with IBM Cognos® Analytics. For more information, see Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.
- Familiarize yourself with backup and restore procedures. It is recommended that you take regular backups of your IBM Cloud Pak for AIOps deployment. For more information, see Backup and restore.
- For more information about health checks and monitoring, see Health checks and monitoring.

Online production installation of IBM Cloud Pak for AIOps (CLI method)

If your cluster is connected to the internet, you can complete a production installation of IBM Cloud Pak® for AIOps with the Red Hat® OpenShift® Container Platform command line interface (CLI).

Before you begin

- You must know whether you are deploying a base deployment or a extended deployment of IBM Cloud Pak for AIOps. For more information, see Incremental adoption.
- Review the Planning section.
- Online installations of IBM Cloud Pak for AIOps can be run entirely as a non-root user, and do not require that user to have sudo access.
- Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).
- If you require details about the permissions that the IBM Cloud Pak for AIOps operators need, see Permissions (IBM Cloud Pak for AIOps).
- A user with `cluster-admin` privileges is needed for the following operations:
  - Create a custom project
  - Install Cert Manager
  - Install the License Service
  - Create the catalog sources
  - Create an OperatorGroup

Important: If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

Installation procedure

Follow these steps to install IBM Cloud Pak for AIOps.

1. Install and configure Red Hat OpenShift
2. Configure storage
3. Retrieve your entitlement key
4. Create environment variables
5. Create a custom project (namespace)
6. Create the entitlement key secret
7. Configure usage data collection
8. Create the catalog sources
9. Install Cert Manager
10. Install the License Service
11. Verify cluster readiness
12. Install the operator
13. Install IBM Cloud Pak for AIOps
14. Verify your installation
15. Create an EgressFirewall to restrict outgoing traffic
16. Access the Cloud Pak for AIOps console

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description

`icr.io`
`cp.icr.io`
`dd0.icr.io`
`dd2.icr.io`
`dd4.icr.io`
`dd6.icr.io`
	Allow access to these hosts on port 443 to enable access to the **`IBM Cloud Container Registry`** and IBM Cloud Pak® foundational services catalog source.

`dd1-icr.ibm-zh.com`
`dd3-icr.ibm-zh.com`
`dd5-icr.ibm-zh.com`
`dd7-icr.ibm-zh.com`
	If you are located in China, also allow access to these hosts on port 443.

`github.com`	Github houses IBM Cloud Pak tools and scripts.
`redhat.com`	Red Hat OpenShift registries that are required for Red Hat OpenShift, and for Red Hat OpenShift upgrades.

For more information, see Configuring your firewall for OpenShift Container Platform.

1. Install and configure Red Hat OpenShift

IBM Cloud Pak for AIOps requires Red Hat OpenShift to be installed and running. You must have administrative access to your Red Hat OpenShift cluster.

For more information about the supported versions of Red Hat OpenShift, see Supported Red Hat OpenShift Container Platform versions.

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation.
2. Install the Red Hat OpenShift command line interface (**`oc`**) on your cluster's boot node and run **`oc login`**. For more information, see the instructions in Getting started with the Red Hat OpenShift CLI.
3. Ensure that the clocks on your Red Hat OpenShift cluster are synchronized. Each Red Hat OpenShift node in the cluster must have access to an NTP server. Red Hat OpenShift nodes use NTP to synchronize their clocks. IBM Cloud Pak for AIOps runs on Red Hat OpenShift and also has this requirement. Discrepancies between the clocks on the Red Hat OpenShift nodes can cause IBM Cloud Pak for AIOps to experience operational issues. See the Red Hat OpenShift documentation for information about how to use a **`MachineConfig`** custom resource to configure chrony to connect to your NTP servers.
4. Optionally configure a custom certificate for IBM Cloud Pak for AIOps to use. You can use either of the following methods:
   - Configure a custom certificate for the Red Hat OpenShift cluster. Follow the instructions in the Red Hat OpenShift documentation Replacing the default ingress certificate. Then, deploy the signing CA certificate into the cluster by following the instructions in the Red Hat OpenShift documentation Replacing the CA Bundle certificate.
   - If you would like to use a custom certificate for IBM Cloud Pak for AIOps only, then after installation is complete follow the instructions in Using a custom certificate.

2. Configure storage

Configure persistent storage for IBM Cloud Pak for AIOps that satisfies your sizing requirements. For more information about storage, see Storage.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **`RWX-storage-class-name`** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

3. Retrieve your entitlement key

Obtain the IBM entitlement key that is assigned to your **IBMid**, which is needed to pull the IBM Cloud Pak for AIOps images from the IBM® Entitled Registry.

1. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
2. In the *Entitlement key* section, select **Copy** to copy the entitlement key to the clipboard. You will need to use this value to set the environment variable $IBM_ENTITLEMENT_KEY in the next step.

4. Create environment variables

Create and then source a shell script named *waiops_var.sh* that defines the environment variables that will be used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets **< ... >** with values for your environment.

You can use the following table to find the values to set for your storage environment variables.

Table 1. Storage provider classes

Storage provider	RWX-storage-class-name	RWO-storage-class-name
IBM Cloud®	ibmc-block-gold	ibmc-block-gold
IBM Cloud® with OADP backup and restore	ibmc-file-gold-gid	ibmc-block-gold
Red Hat® OpenShift® Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
Red Hat® OpenShift® Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Global Data Platform	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc
IBM Storage Scale Container Native	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc
Portworx	px-csi-aiops	px-csi-aiops
Portworx (multi-zone HA)	px-csi-aiops-mz	px-csi-aiops-mz
AWS native storage	gp3-csi	gp3-csi
AWS native storage with OADP backup and restore	efs-sc	gp3-csi

Note: To confirm that you have the storage classes for your chosen storage provider as shown in the table, run **oc get sc**.

```
#============================================================================================================================
# Cloud Pak for AIOps installation variables
#============================================================================================================================
export CP4AIOPS_NAME=ibm-cp-aiops
export CP4AIOPS_SIZE=large # Set to `small` if you only require a starter, non-production deployment.
export SECURE_TUNNEL=false # Set to `true` to install Secure Tunnel, otherwise set to `false`.
export PROJECT_CP4AIOPS=cp4aiops
export ACCEPT_LICENSE=false # Set to `true` to agree to the license terms, otherwise install will fail.
export CATALOG_SRC_CP4AIOPS=ibm-aiops-catalog

# ----------------------------------------------------------------------------------------------------------------------------
# Incremental adoption - set your deployment type
# Set to `true` to install an extended deployment with log anomaly detection and ticket analysis capabilities
# Set to `false` to install a base deployment without log anomaly detection and ticket analysis capabilities
# ----------------------------------------------------------------------------------------------------------------------------
export LOG_ANOMALY=false

# ----------------------------------------------------------------------------------------------------------------------------
# Storage
# ----------------------------------------------------------------------------------------------------------------------------
export STG_CLASS=<RWX-storage-class-name>
export STG_CLASS_BLOCK=<RWO-storage-class-name>

# ----------------------------------------------------------------------------------------------------------------------------
# Your customer details
# ----------------------------------------------------------------------------------------------------------------------------
export CUSTOMER_NAME=<your company name>
export CUSTOMER_ICN=<your IBM Customer Number>
export CUSTOMER_ENVIRONMENT=<Set to `trial`, `poc`, or `production`>

# ----------------------------------------------------------------------------------------------------------------------------
# IBM Entitled Registry
# ----------------------------------------------------------------------------------------------------------------------------
export IBM_ENTITLEMENT_KEY=<IBM-entitlement-key> # Set to the entitlement key retrieved in previous step.

# ----------------------------------------------------------------------------------------------------------------------------
# `OwnNamespace` installation mode:  leave INSTALL_MODE_NAMESPACE as it is.
# `AllNamespaces` installation mode: change to export INSTALL_MODE_NAMESPACE=openshift-operators
# ----------------------------------------------------------------------------------------------------------------------------
export INSTALL_MODE_NAMESPACE=${PROJECT_CP4AIOPS}

# ----------------------------------------------------------------------------------------------------------------------------
# Topology resource group terminology
# Specify `application` or `service` as the terminology to be used for collections of topology resource
```

```
# groups. The default is `application`.
# ----------------------------------------------------------------------------------------------------------
export TOPOLOGY_TERMINOLOGY=application
```

If you need help with deciding on the values to set for these environment variables, see the following topics.

- LOG_ANOMALY: Incremental adoption
- CP4AIOPS_SIZE: Sizing
- SECURE_TUNNEL: Secure Tunnel
- INSTALL_MODE_NAMESPACE: Operator installation mode

You can update your deployment type after installation. For more information, see Updating the deployment type.

Note: You can set a different value for $PROJECT_CP4AIOPS and $CP4AIOPS_NAME if you want. However, you must not use the **default**, **kube-system**, **kube-public**, **openshift-node**, **openshift-infra**, or **openshift** projects (namespaces) for $PROJECT_CP4AIOPS. This is because IBM Cloud Pak for AIOps uses Security Context Constraints (SCC), and SCCs cannot be assigned to pods created in one of the default Red Hat OpenShift projects (namespaces).

Run the following command to source your script and set the environment variables:

```
. ./waiops_var.sh
```

5. Create a custom project (namespace)

Run the following command to create a project (namespace) to deploy IBM Cloud Pak for AIOps into.

```
oc create namespace "${PROJECT_CP4AIOPS}"
```

6. Create the entitlement key secret

Run the following command to create an image pull secret called *ibm-entitlement-key* to enable your deployment to pull the IBM Cloud Pak for AIOps images from the IBM Entitled Registry.

```
oc create secret docker-registry ibm-entitlement-key --docker-username=cp --docker-password="${IBM_ENTITLEMENT_KEY}" --docker-server=cp.icr.io --namespace=${PROJECT_CP4AIOPS}
```

7. Configure usage data collection

To help the development of IBM Cloud Pak for AIOps, daily aggregated usage data is collected to analyse how IBM Cloud Pak for AIOps is used. The usage data is collected by the **cp4waiops-metricsprocessor** pod, and is sent to and stored in IBM controlled GDPR-compliant systems. The collection of usage data is enabled by default, but can be disabled. For transparency, the **cp4waiops-metricsprocessor** pod's logs contain all the information that is collected. The usage data that is collected is numeric, or is about the deployment type and platform. It does not include email addresses, passwords, or specific details. Only the following data is collected:

- Current number of applications
- Current number of alerts (all severities aggregated)
- Current number of incidents (all priorities aggregated)
- Current number of policies (includes predefined and user created)
- Current number of runbooks run since installation
- Current number of integrations of each type (For example ServiceNow, Instana, Falcon Logscale)
- Secure tunnel enablement: whether *connection* (which controls whether you can create a secure tunnel) is enabled in the *Installation* custom resource
- Deployment type: base deployment or extended deployment
- Deployment platform: Red Hat® OpenShift® Container Platform or Linux®

Configuring the collection of usage data

If you do not want to disable the collection of usage data, run the following command to configure the usage data with your customer details.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME} --from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT}
```

If you have a firewall enabled, ensure that outbound traffic to https://api.segment.io is allowed.

Important: Usage data without your customer details is still collected even if you do not create this secret. If you do not want any usage data collected, then you must run the command that is given in *Disabling the collection of usage data*.

Disabling the collection of usage data

If you want to disable the collection of usage data, run the following command.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME} --from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT} --from-literal=enableCollection=false
```

Note: You can update your usage data collection preferences after installation. For more information, see Updating usage data collection preferences.

8. Create the catalog sources

1. Run the following command to create the catalog sources for IBM Cloud Pak for AIOps and IBM Cloud Pak® foundational services Cert Manager and License Service in the *openshift-marketplace* namespace.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ${CATALOG_SRC_CP4AIOPS}
  namespace: openshift-marketplace
spec:
  displayName: ${CATALOG_SRC_CP4AIOPS}
  publisher: IBM Content
  sourceType: grpc
  image:
icr.io/cpopen/${CATALOG_SRC_CP4AIOPS}@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cert-manager-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cert-manager
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-cert-manager-operator-catalog
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-licensing-catalog
  namespace: openshift-marketplace
spec:
  displayName: IBM License Service Catalog
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-licensing-catalog
EOF
```

2. Verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* **CatalogSource** objects are in the output that is returned by the following command:

   ```
   oc get CatalogSources -n openshift-marketplace
   ```

   Example output:

   ```
   oc get CatalogSources -n openshift-marketplace
   NAME                     DISPLAY                     TYPE   PUBLISHER   AGE
   ibm-aiops-catalog        ibm-aiops-catalog           grpc   IBM         2m
   ibm-cert-manager-catalog ibm-cert-manager            grpc   IBM         2m
   ibm-licensing-catalog    IBM License Service Catalog grpc   IBM         2m
   ```

9. Install Cert Manager

Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

1. Run the following command to create the resource definitions that you need:

   ```
   cat << EOF | oc apply -f -
   apiVersion: v1
   kind: Namespace
   metadata:
     name: ibm-cert-manager
   ---
   apiVersion: operators.coreos.com/v1
   kind: OperatorGroup
   metadata:
     name: ibm-cert-manager-operator-group
     namespace: ibm-cert-manager
   ---
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: ibm-cert-manager-operator
     namespace: ibm-cert-manager
   spec:
     channel: v4.2
     installPlanApproval: Automatic
     name: ibm-cert-manager-operator
     source: ibm-cert-manager-catalog
     sourceNamespace: openshift-marketplace
   EOF
   ```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

```
oc -n ibm-cert-manager get pods
```

Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-cainjector-674854c49d-vstq4   1/1     Running   0          8d
cert-manager-controller-646d4bd6fd-zwmqm   1/1     Running   0          8d
cert-manager-webhook-8598787c8-s41kt       1/1     Running   0          8d
ibm-cert-manager-operator-c96957695-dkxnm  1/1     Running   0          8d
```

10. Install the License Service

Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

1. Run the following command to create the resource definitions that you need:

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Namespace
metadata:
  name: ibm-licensing
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-licensing-operator-group
  namespace: ibm-licensing
spec:
  targetNamespaces:
  - ibm-licensing
---
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-licensing-operator-app
  namespace: ibm-licensing
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-licensing-operator-app
  source: ibm-licensing-catalog
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

```
oc -n ibm-licensing get pods
```

Example output for a successful IBM Cloud Pak® foundational services License Service installation:

```
NAME                                              READY   STATUS    RESTARTS   AGE
ibm-licensing-operator-db4cd746c-xzmlf            1/1     Running   0          8d
ibm-licensing-service-instance-596b99588f-76cc5   1/1     Running   0          8d
```

For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

11. Verify cluster readiness

Run the prerequisite checker script to verify whether your Red Hat OpenShift cluster is correctly set up for a IBM Cloud Pak for AIOps installation.

Download the prerequisite checker script from github.com/IBM, and run it with the following command:

```
./prereq.sh -n ${PROJECT_CP4AIOPS}
```

Important: If you are installing on a multi-zone cluster, then also specify the `-m` flag to assess whether there are sufficient resources to withstand a zone outage.

Example output:

```
# ./prereq.sh -n cp4aiops

[INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

CLI: oc

[INFO] ================================Platform Version Check================================
[INFO] Checking Platform Type....
[INFO] You are using Openshift Container Platform

```

12. Install the operator

For more information about installing operators, see Adding Operators to a cluster in the Red Hat OpenShift documentation.

For more information about the operators which are installed with IBM Cloud Pak for AIOps, see Operator Details.

Note: During the initial installation of Cloud Pak for AIOps, Kubernetes jobs might fail and re-run. If a job succeeds on the second or third attempt, there can be one or two pods in `Error` state and one pod in the `Completed` state. If the job fails repeatedly, the attempt is abandoned, and the logs from failed pods are used to determine the cause of the failure. When you determine the cause for the failure, you can delete the job, and the operator can recreate it to reattempt the operations.

1. Create an OperatorGroup.

   Important: Skip this step if you are installing using the 'All Namespaces' installation mode. Check that you set `INSTALL_MODE_NAMESPACE` correctly in step 4, and proceed to the next step, Install the IBM Cloud Pak for AIOps operator.

   If you are installing using the 'OwnNamespace' installation mode, then you must create an operator group in your custom project (namespace), or the IBM Cloud Pak for AIOps operator will not install. There might be an operator group for managing a namespace for given APIs. If there is an operator group for the namespace, do not create a second one.

   Create the operator group by running the following command:

   ```
   cat << EOF | oc apply -f -
   apiVersion: operators.coreos.com/v1
   kind: OperatorGroup
   metadata:
     name: cp4aiops-operator-group
   ```

```
  namespace: ${PROJECT_CP4AIOPS}
spec:
  targetNamespaces:
    - "${PROJECT_CP4AIOPS}"
EOF
```

2. Install the IBM Cloud Pak for AIOps operator.

   Run the following command.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-aiops-orchestrator
  namespace: $INSTALL_MODE_NAMESPACE
spec:
  channel: v4.8
  installPlanApproval: Automatic
  name: ibm-aiops-orchestrator
  source: ${CATALOG_SRC_CP4AIOPS}
  sourceNamespace: openshift-marketplace
EOF
```

   Warning: installPlanApproval must not be changed to *Manual*. Manual approval, which requires the manual review and approval of the generated InstallPlans, is not supported. Incorrect timing or ordering of manual approvals of InstallPlans can result in a failed installation.

3. After a few minutes, the IBM Cloud Pak for AIOps operator is installed. Verify that the all of the components have a state of **Succeeded** by running the following command:

```
oc get csv -n ${INSTALL_MODE_NAMESPACE} | egrep "ibm-aiops-orchestrator"
```

   Example output:

```
$ oc get csv -n ${INSTALL_MODE_NAMESPACE} | egrep "ibm-aiops-orchestrator"
ibm-aiops-orchestrator.v4.8.0         IBM Cloud Pak for AIOps                4.8.0   Succeeded
```

13. Install IBM Cloud Pak for AIOps

Create an instance of the IBM Cloud Pak for AIOps custom resource. A maximum of one IBM Cloud Pak for AIOps custom resource is allowed per cluster.

Use one of the following YAML codeblocks to create an instance of the IBM Cloud Pak for AIOps custom resource, depending on whether you are installing on a multi-zone cluster.

Installing on a non multi-zone cluster:

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ${CP4AIOPS_NAME}
  namespace: ${PROJECT_CP4AIOPS}
spec:
  size: ${CP4AIOPS_SIZE}
  storageClass: ${STG_CLASS}
  storageClassLargeBlock: ${STG_CLASS_BLOCK}
  imagePullSecret: ibm-entitlement-key
  topologyModel: ${TOPOLOGY_TERMINOLOGY}
  license:
    accept: ${ACCEPT_LICENSE}
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: ${SECURE_TUNNEL}
  - name: logAnomalyDetection
    enabled: ${LOG_ANOMALY}
EOF
```

Installing on a multi-zone cluster:

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ${CP4AIOPS_NAME}
  namespace: ${PROJECT_CP4AIOPS}
spec:
  size: ${CP4AIOPS_SIZE}
  storageClass: ${STG_CLASS}
  storageClassLargeBlock: ${STG_CLASS_BLOCK}
  imagePullSecret: ibm-entitlement-key
  topologyModel: ${TOPOLOGY_TERMINOLOGY}
```

```
  license:
    accept: ${ACCEPT_LICENSE}
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: ${SECURE_TUNNEL}
  - name: logAnomalyDetection
    enabled: ${LOG_ANOMALY}
  zones:
  - name: <zone_name1>
  - name: <zone_name2>
  - name: <zone_name3>
EOF
```

Where **<zone_name1>**, **<zone_name2>**, and **<zone_name3>** exactly match the zone labels that you applied to each of your nodes in step 1a of Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA).

Warning: The pakModules **aiopsFoundation**, **applicationManager**, and **aiManager** must be enabled as in the preceding YAML. Do not change these values to false.

14. Verify your installation

Run the following command to check that the **PHASE** of your installation is **Updating**.

```
oc get installations.orchestrator.aiops.ibm.com -n ${PROJECT_CP4AIOPS}
```

Example output:

```
NAME                  PHASE      LICENSE    STORAGECLASS    STORAGECLASSLARGEBLOCK    AGE
ibm-cp-aiops          Updating   Accepted   rook-cephfs     rook-ceph-block           3m
```

It takes around 60-90 minutes for the installation to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **PHASE** of your installation changes to **Running**. If your installation phase does not change to **Running**, then use the following command to find out which components are not ready:

```
oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'Not Ready'
```

Example output:

```
lifecycleservice: Not Ready
zenservice: Not Ready
```

To see details about why a component is **Not Ready** run the following command, where **<component>** is the component that is not ready, for example **zenservice**.

```
oc get <component> -o yaml -n ${PROJECT_CP4AIOPS}
```

(Optional) You can also download and run a status checker script to see information about the status of your deployment. For more information about how to download and run the script, see github.com/IBM.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

15. Create an EgressFirewall

There is no egress firewall policy defined when you install IBM Cloud Pak for AIOps, so outgoing traffic from workload pods to the internal and external network is unrestricted.

To create a more secure environment, use the following steps.

1. Create an **EgressFirewall** on your Red Hat OpenShift cluster to limit egress from the IBM Cloud Pak for AIOps project (namespace).

   For more information about creating an **EgressFirewall**, see Configuring an egress firewall for a project.

   Note: You can have only one **EgressFirewall** per project/namespace.

2. Configure exceptions to the **EgressFirewall**.

   Edit your **EgressFirewall** to add exceptions for the following IBM Cloud Pak for AIOps components that have egress dependencies, otherwise these components fail when they attempt egress.

   1. Allow egress to any external services, such as the following integrations:
      - Kubernetes
      - GitHub
      - Microsoft® Teams
      - ServiceNow
      - Slack
      - VMware® vCenter

2. Configure your **EgressFirewall** to allow traffic for your GitHub, Kubernetes, ServiceNow, and VMware vCenter integrations.

   Edit your **EgressFirewall** to allow or deny egress, as in the following example. Substitute values for **dnsName** and **cidrSelector** that are the DNS names and addresses of your GitHub, Kubernetes, ServiceNow, or VMware vCenter sources.

```
kind: EgressFirewall
metadata:
  name: default
spec:
  egress:
  - type: Allow
    to:
      cidrSelector: <1.2.3.0/24>
  - type: Allow
    to:
      dnsName: <www.github.com>
  - type: Allow
    to:
      dnsName: <www.developer.kubernetes.com>
  - type: Allow
    to:
      dnsName: <www.developer.servicenow.com>
  - type: Allow
    to:
      dnsName: <www.developer.vcenter.com>
  - type: Deny
    to:
      cidrSelector: <0.0.0.0/0>
```

16. Access the Cloud Pak for AIOps console

After you successfully install IBM Cloud Pak for AIOps, get the URL for accessing the Cloud Pak for AIOps console.

1. Use the following command to get the URL to access the Cloud Pak for AIOps console:

   ```
   oc get route -n ${PROJECT_CP4AIOPS} cpd -o jsonpath='{.spec.host}'
   ```

   The following output is a sample output:

   ```
   cpd-cp4aiops.apps.mycluster.mydomain
   ```

   Based on the sample output, your console URL would be **https://cpd-cp4aiops.apps.mycluster.mydomain**

2. Enter the URL in your browser to open the Cloud Pak for AIOps console. Log in with your username and password.

Find the IBM Cloud Pak for AIOps console username and password

The default username to access the Cloud Pak for AIOps console is **admin**. You can check the default username and their password with the following commands.

Note: This information is for the **IBM provided credentials (admin only)** authentication type.

1. Find the default username.

   ```
   oc -n ${PROJECT_CP4AIOPS} get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_username}' | base64 -d
   && echo
   ```

2. Get the password for the **admin** username.

   ```
   oc -n ${PROJECT_CP4AIOPS} get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d
   ```

   The following extract shows a sample output:

   ```
   EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA
   ```

   Based on the sample output, your password would be **EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA**.

Important: You can change this default password at any time. For more information, see Changing the cluster administrator password.

What to do next

- Define integrations and applications with Defining.
- You can integrate with IBM Cognos® Analytics. For more information, see Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.
- Familiarize yourself with backup and restore procedures. It is recommended that you take regular backups of your IBM Cloud Pak for AIOps deployment. For more information, see Backup and restore.
- For more information about health checks and monitoring, see Health checks and monitoring.

Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline)

If your cluster is not connected to the internet, you can install IBM Cloud Pak® for AIOps in your cluster by using either a bastion host, portable compute device, or a portable storage device.

The IBM Catalog Management Plug-in for IBM Cloud Pak® is used for the deployment of IBM Cloud Paks® in a disconnected environment. It simplifies the process for discovering IBM product images, uses standard tools for registry and cluster access, and extends the Red Hat OpenShift CLI (`oc`) capability to streamline the air-gapped deployment process.

Overview

It is common in production to have a cluster that does not have internet access. In these cases, you can still install IBM Cloud Pak for AIOps and Red Hat® OpenShift® Container Platform in an air-gapped (otherwise known as offline or disconnected) environment. Unlike online installations, air-gapped installations require you to enable the IBM Operator Catalog to mimic a typical online installation by using images in your own registry.

The following diagram provides an overview of air-gapped installation scenarios for portable compute, portable storage, and bastion hosts:

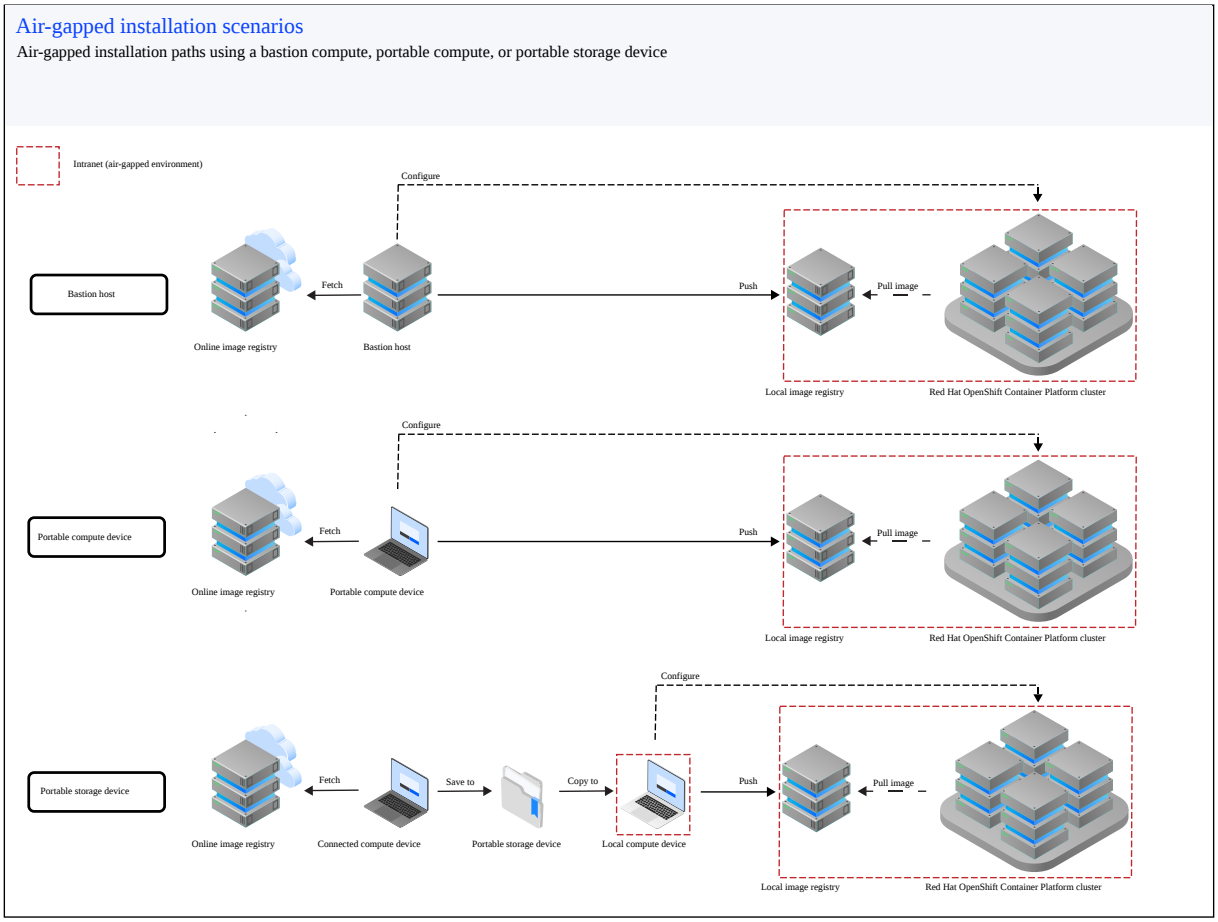

Figure 1. Air-gap scenario

All of these scenarios use Container Application Software for Enterprises (CASE) files. CASE is a specification that defines the metadata and structure for packaging, managing, and unpacking containerized applications.

You can store the product code and images to a portable compute device (like a laptop), portable storage device (like an external hard disk drive), or a bastion host and then transfer them to a local air-gapped network. The images that are stored are large, and you must ensure that each of your airgap devices have enough storage, as follows.

- Bastion host method - the local target registry must have at least 140 GB of storage space.
- Portable device methods - the portable device and the local target registry must each have at least 140 GB of storage space.

Table 1. Air-gapped installation scenarios

Air-gapped installation approach	Example	Description
Bastion host	Bastion host	The bastion host has access to the public internet and the air-gapped environment where a local target registry and a Red Hat OpenShift Container Platform cluster are. The IBM Cloud Pak for AIOps images are replicated from the IBM Entitled Registry through the bastion server directly to the local target registry behind the firewall.
Portable compute device	Laptop	IBM Cloud Pak for AIOps images are downloaded from the IBM Entitled Registry to a file system on a portable compute device. The portable compute device is then disconnected from the internet and brought into the air-gapped environment so that the images can be copied from the file system to the local target registry behind the firewall.

Air-gapped installation approach	Example	Description
Portable storage device	Portable hard disk drive	IBM Cloud Pak for AIOps images are downloaded from the IBM Entitled Registry through an internet connected device to a file system on a portable storage device. The portable storage device is then disconnected and brought into the air-gapped environment so that the images can be copied from the file system to the local target registry behind the firewall.

Installation methods

Choose one of the following deployment methods to complete an air-gapped installation.

- Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline) using a bastion host
- Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline) using a portable device

Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline) using a bastion host

If your cluster is not connected to the internet, you can deploy a production installation of IBM Cloud Pak® for AIOps on your Red Hat® OpenShift® Container Platform cluster by using a bastion host.

In this scenario, your air-gapped (offline) environment has a target registry, and a Red Hat OpenShift cluster on which IBM Cloud Pak for AIOps is to be installed. The bastion host has access to the internet and to the offline environment. IBM Cloud Pak for AIOps images are mirrored from the internet through the bastion server to the target registry in the offline environment. IBM Cloud Pak for AIOps can then be installed in the offline environment by using the target registry.

Before you begin

- You must know whether you are deploying a base deployment or a extended deployment of IBM Cloud Pak for AIOps. For more information, see Incremental adoption.
- Review the Planning section. Your environment must meet the system requirements.
- Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).
- The following commands must be run as a root user or by a user with sudo access: `yum install podman` and `podman login`. The rest of the procedure can be run as a non-root user.
- If you require details about the permissions that are needed by the IBM Cloud Pak for AIOps operators, see Permissions (IBM Cloud Pak for AIOps).
- A user with `cluster-admin` privileges is needed for the following operations:
  - Install Cert Manager
  - Install the License Service
  - Create a custom project
  - Configure the cluster
  - Create the catalog source
  - Create an OperatorGroup

Important: If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

The following procedure is based on an Red Hat OpenShift 4.17 environment and includes links for that version. If your environment uses a different supported version of Red Hat OpenShift, ensure that you follow the Red Hat OpenShift documentation for that version.

Installation procedure

1. Set up the mirroring environment
2. Download the CASE
3. Mirror images
4. Configure storage
5. Install IBM Cloud Pak for AIOps

1. Set up the mirroring environment

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description

`icr.io`
`cp.icr.io`
`dd0.icr.io`
`dd2.icr.io`
`dd4.icr.io`
`dd6.icr.io`
	Allow access to these hosts on port 443 to enable access to the `IBM Cloud Container Registry`, CASE OCI artifact, and IBM Cloud Pak® foundational services catalog source.

Site	Description

`dd1-icr.ibm-zh.com`
`dd3-icr.ibm-zh.com`
`dd5-icr.ibm-zh.com`
`dd7-icr.ibm-zh.com`
	If you are located in China, also allow access to these hosts on port 443.

`github.com`	Github houses CASE files, IBM Cloud Pak tools and scripts.
`redhat.com`	Red Hat OpenShift registries that are required for Red Hat OpenShift, and for Red Hat OpenShift upgrades.

1.1 Download documentation and scripts for offline access

Download the following documentation and scripts that you might need to access during your IBM Cloud Pak for AIOps installation, and copy them to your air-gapped environment.

1. IBM Cloud Pak for AIOps 4.8.0 documentation

   Download the Cloud Pak for AIOps 4.8.0 PDF (this documentation) so that you can access it offline.

2. IBM Cloud Pak for AIOps 4.8.0 scripts

   - The prerequisite checker script verifies whether your Red Hat OpenShift cluster is correctly set up for a IBM Cloud Pak for AIOps installation. You will need to run this script in step 5.7 Verify cluster readiness. Download this script from github.com/IBM.
   - An uninstall script can be downloaded from github.com/IBM.
   - (Optional) The status checker script can be used in step 5.9 Install IBM Cloud Pak for AIOps to give information about the status of your deployment. The use of this script is optional, as status can be found directly from the **`ibm-aiops-orchestrator`** custom resource. This script can be downloaded from github.com/IBM.

3. Red Hat OpenShift documentation

   The Red Hat OpenShift documentation can be downloaded for offline access from Red Hat. The **`Security and compliance`**, **`Installing`**, **`CLI Tools`**, **`Images`**, and **`Operators`** sections are referenced by this documentation.

1.2 Install and configure Red Hat OpenShift

IBM Cloud Pak for AIOps requires Red Hat OpenShift to be installed and running on your target cluster. You must have administrative access to your Red Hat OpenShift cluster.

For more information about the supported versions of Red Hat OpenShift, see Supported Red Hat OpenShift Container Platform versions.

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation. Information about installing a cluster in a restricted network is given in Mirroring images for a disconnected installation.

2. Install the Red Hat OpenShift command line interface (**`oc`**) on your cluster's boot node and run **`oc login`**. For more information, see the instructions in Getting started with the Red Hat OpenShift CLI.

3. Ensure that the clocks on your Red Hat OpenShift cluster are synchronized. Each Red Hat OpenShift node in the cluster must have access to an NTP server. Red Hat OpenShift nodes use NTP to synchronize their clocks. IBM Cloud Pak for AIOps runs on Red Hat OpenShift and also has this requirement. Discrepancies between the clocks on the Red Hat OpenShift nodes can cause IBM Cloud Pak for AIOps to experience operational issues. See the Red Hat OpenShift documentation for information about how to use a **`MachineConfig`** custom resource to configure chrony to connect to your NTP servers.

4. Optionally configure a custom certificate for IBM Cloud Pak for AIOps to use. You can use either of the following methods:

   - Configure a custom certificate for the Red Hat OpenShift cluster. Follow the instructions in the Red Hat OpenShift documentation Replacing the default ingress certificate. Then, deploy the signing CA certificate into the cluster by following the instructions in the Red Hat OpenShift documentation Replacing the CA Bundle certificate.
   - If you would like to use a custom certificate for IBM Cloud Pak for AIOps only, then after installation is complete follow the instructions in Using a custom certificate.

1.3 Set up a target registry

You must have a local Docker type production-grade registry available to store the IBM Cloud Pak for AIOps images in. The registry must meet the following requirements:

- supports Docker Manifest V2, Schema 2.
- supports multi-architecture images.
- is accessible from the Red Hat OpenShift cluster nodes.
- allows path separators in the image name.
- you have the username and password for a user who can read from and write to the registry.
- must have 140 GB of storage to hold all the software that is to be transferred to the target registry.

If you do not already have a suitable production-grade registry available, then you must install and configure one. For more information, see About the mirror registry in the Red Hat OpenShift documentation.

Important: Do not use the Red Hat OpenShift image registry as your target registry. The Red Hat OpenShift registry does not support multi-architecture images or path separators in the image name.

1.4 Prepare a host

Prepare a bastion host that can connect to the internet and to the air-gapped network with access to the Red Hat OpenShift cluster and the target registry. Your host must be on a Linux® x86_64 or Mac platform with any operating system that the IBM Cloud Pak® CLI and the Red Hat OpenShift CLI support. If you are on a Windows® platform, you must run the actions in a Linux® x86_64 VM or from a Windows Subsystem for Linux (WSL) terminal.

Complete the following steps on your host.

1. Install Podman.

   To install Podman, see the Podman Installation Instructions.

   Note: Docker is not shipped or supported for Red Hat Enterprise Linux (RHEL) 8. The Podman container engine replaced docker as the preferred, maintained, and supported container runtime of choice for Red Hat Enterprise Linux 8 systems. For more information, see Running containers without Docker in the Red Hat documentation.

2. Install the Red Hat OpenShift CLI tool, **`oc`**.

   `oc` is required for Red Hat OpenShift management. For more information, see Getting started with the OpenShift CLI in the Red Hat OpenShift documentation.

1.5 Install the IBM Catalog Management Plug-in for IBM Cloud Pak®

The IBM Catalog Management Plug-in for IBM Cloud Pak (**`ibm-pak-plugin`**) is used for the deployment of IBM Cloud Paks® in a disconnected environment. It simplifies the process for discovering required IBM product images and uses standard tools for registry and cluster access. The ibm-pak-plugin also extends the Red Hat OpenShift CLI (**`oc`**) capability to streamline the process of delivering installation images to the IBM Cloud Pak in an air-gapped environment.

1. Download and install the most recent version of the **`ibm-pak-plugin`** for your host operating system from github.com/IBM.

2. Run the following command to extract the files.

   ```
   tar -xf oc-ibm_pak-linux-amd64.tar.gz
   ```

3. Run the following command to move the file to the **`/usr/local/bin`** directory.

   ```
   mv oc-ibm_pak-linux-amd64 /usr/local/bin/oc-ibm_pak
   ```

   Note: If you are installing as a non-root user, you must use sudo.

4. Confirm that the **`ibm-pak-plugin`** is installed by running the following command.

   ```
   oc ibm-pak --help
   ```

   Expected result: The **`ibm-pak-plugin`** usage is displayed.

2. Download the CASE

Set environment variables on the bastion host, and connect to the internet so that you can download the IBM Cloud Pak for AIOps CASE files.

Note: Save a copy of your environment variable values to a file that you can use as a reference when you are completing your air-gapped installation tasks.

1. Create the following environment variables.

   ```
   export CASE_NAME=ibm-cp-waiops
   export CASE_VERSION=1.14.0
   export CASE_INVENTORY_SETUP=cpwaiopsSetup
   export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
   export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   export TARGET_REGISTRY_USER=<username>
   export TARGET_REGISTRY_PASSWORD=<password>
   ```

   The target registry is the registry where the IBM Cloud Pak for AIOps images are mirrored to, and accessed from by the Red Hat OpenShift cluster, as setup in 1.3 Set up a target registry.

   If your bastion host must connect to the internet through a proxy, then also set the following environment variables.

   ```
   export https_proxy=http://proxy-server-hostname:port
   export http_proxy=http://proxy-server-hostname:port
   ```

2. Connect your host to the internet and disconnect it from the local air-gapped network.

3. Download the IBM Cloud Pak for AIOps installer and image inventory to your host.

   ```
   oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
   ```

   The CASE is downloaded to **`~/.ibm-pak/data/cases/$CASE_NAME/$CASE_VERSION`**. The logs files are available at **`~/.ibm-pak/logs/oc-ibm_pak.log`**.

   Note: If you do not specify the CASE version, then the latest CASE is downloaded. The root directory that is used by **`ibm-pak-plugin`** is **`~/.ibm-pak`**. If required, the root directory can be configured by setting the **`IBMPAK_HOME`** environment variable.

3. Mirror images

Complete the following steps to mirror the IBM Cloud Pak for AIOps, IBM Cloud Pak foundational services Cert Manager, and IBM Cloud Pak foundational services License Service images from the internet to the target registry in the air-gapped environment.

3.1. Generate mirror manifests

Run the following command to generate mirror manifests to be used when mirroring the images to the target registry.

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} ${TARGET_REGISTRY} --version ${CASE_VERSION} --filter ibm_es_opensearch
```

A new directory named **~/.ibm-pak/mirror** is created when you issue the **oc ibm-pak generate mirror-manifests** command. The files **images-mapping.txt** and **image-content-source-policy.yaml** are generated at **~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION**.

3.2. Authenticate with the registries

Log in to the registries to generate an authentication file containing the registry credentials, and then create an environment variable that has the location of the authentication file. This file is used later to enable the **oc image mirror** command to pull the images from the IBM Entitled Registry, and push them to the target registry.

1. Get the authentication credentials for the IBM Entitled Registry.
    1. To obtain the entitlement key that is assigned to your IBMid, log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
    2. In the *Entitlement keys* section, select **Copy key** to copy the entitlement key.
2. Run the following command to create an environment variable that contains your entitlement key.

    ```
    export ENTITLED_REGISTRY_PASSWORD=<key>
    ```

    Where **<key>** is the entitlement key that you copied in the previous step.
3. Store the authentication credentials for the IBM Entitled Registry and the target registry.

    Run the following commands:

    ```
    podman login cp.icr.io -u cp -p ${ENTITLED_REGISTRY_PASSWORD}
    podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD}
    export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
    unset ENTITLED_REGISTRY_PASSWORD
    ```

    Note: The authentication file is usually at **${XDG_RUNTIME_DIR}/containers/auth.json**. For more information, see the Options section in the Podman documentation.

3.3. Mirror the images

Complete these steps on your host that is connected to both the local registry and the Red Hat OpenShift cluster.

Mirror images to the target registry.

```
nohup oc image mirror \
-f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/images-mapping.txt \
-a ${REGISTRY_AUTH_FILE} \
--filter-by-os '.*' \
--insecure \
--skip-multiple-scopes \
--max-per-registry=1 > my-mirror-progress.txt 2>&1 &
```

The UNIX command **nohup** is used to ensure that the mirroring process continues even if there is a loss of network connection, and redirection of output to a file provides improved monitoring and error visibility.

Run the following command if you want to see the progress of the mirroring:

```
tail -f my-mirror-progress.txt
```

Note: If an error occurs during mirroring, the mirror command can be rerun.

3.4 Configure the cluster

1. Log in to your Red Hat OpenShift cluster.

    You can identify your specific **oc login** command by clicking the user menu in the upper left of the Red Hat OpenShift console, and then clicking **Copy Login Command**.

    Example:

    ```
    oc login <server> -u <cluster username> -p <cluster pass>
    ```
2. Update the global image pull secret for your Red Hat OpenShift cluster.

    Follow the steps in the Red Hat OpenShift documentation topic Updating the global cluster pull secret.

    These steps enable your cluster to have authentication credentials in place to pull images from your TARGET_REGISTRY as specified in the **image-content-source-policy.yaml**, which you will apply to your cluster in the next step.
3. Create the **ImageContentSourcePolicy**.

    Run the following command to create the ImageContentSourcePolicy.

    ```
    oc apply -f  ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/image-content-source-policy.yaml
    ```
4. Verify that the **ImageContentSourcePolicy** resource is created.

```
oc get imageContentSourcePolicy
```

5. Verify your cluster node status.

```
oc get MachineConfigPool -w
```

Important: After the `ImageContentsourcePolicy` and global image pull secret are applied, the configuration of your nodes will be updated sequentially. Wait until all the `MachineConfigPools` are updated before you proceed to the next step.

6. (Optional) If you use an insecure registry, you must add the target registry to the cluster's `insecureRegistries` list.

```
oc patch image.config.openshift.io/cluster --type=merge \
-p '{"spec":{"registrySources":{"insecureRegistries":["'${TARGET_REGISTRY}'"]}}}'
```

4. Configure storage

The storage configuration must satisfy your sizing requirements. Two storage classes are needed for installing IBM Cloud Pak for AIOps. For more information, see Storage.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the `RWX-storage-class-name` in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

5. Install IBM Cloud Pak for AIOps

Now that the images are mirrored to your air-gapped environment, you can deploy IBM Cloud Pak for AIOps to that environment. To install IBM Cloud Pak for AIOps, complete the following steps.

- 5.1 Create environment variables
- 5.2 Create the catalog source
- 5.3 Create a custom project
- 5.4 Configure usage data collection
- 5.5 Install Cert Manager
- 5.6 Install the License Service
- 5.7 Verify cluster readiness
- 5.8 Install the operator
- 5.9 Install IBM Cloud Pak for AIOps
- 5.10 Create an EgressFirewall
- 5.11 Access the Cloud Pak for AIOps console

5.1 Create environment variables

Create and then source a shell script named *waiops_var.sh* that defines the environment variables that will be used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets `< ... >` with values for your environment.

You can use the following table to find the values to set for your storage environment variables.

Table 2. Storage provider classes

Storage provider	RWX-storage-class-name	RWO-storage-class-name
IBM Cloud®	ibmc-block-gold	ibmc-block-gold
IBM Cloud® with OADP backup and restore	ibmc-file-gold-gid	ibmc-block-gold
Red Hat® OpenShift® Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
Red Hat® OpenShift® Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Global Data Platform	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc
IBM Storage Scale Container Native	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc
Portworx	px-csi-aiops	px-csi-aiops
Portworx (multi-zone HA)	px-csi-aiops-mz	px-csi-aiops-mz
AWS native storage	gp3-csi	gp3-csi
AWS native storage with OADP backup and restore	efs-sc	gp3-csi

```
#============================================================================================================
# Cloud Pak for AIOps installation variables
#============================================================================================================

export CP4AIOPS_NAME=ibm-cp-aiops
export CP4AIOPS_SIZE=large # Set to small if you only require a starter non-production deployment.
export SECURE_TUNNEL=false # Set to `true` to install Secure Tunnel, otherwise set to `false`.
export PROJECT_CP4AIOPS=cp4aiops
export ACCEPT_LICENSE=false # Set to `true` to agree to the license terms, otherwise install will fail.
export CATALOG_SRC_CP4AIOPS=ibm-aiops-catalog
```

```
# ------------------------------------------------------------------------------------------------------------------
# Incremental adoption - set your deployment type
# Set to `true` to install an extended deployment with log anomaly detection and ticket analysis capabilities
# Set to `false` to install a base deployment without log anomaly detection and ticket analysis capabilities
# ------------------------------------------------------------------------------------------------------------------
export LOG_ANOMALY=false

# ------------------------------------------------------------------------------------------------------------------
# Storage
# ------------------------------------------------------------------------------------------------------------------
export STG_CLASS=<RWX-storage-class-name>
export STG_CLASS_BLOCK=<RWO-storage-class-name>

# ------------------------------------------------------------------------------------------------------------------
# Your customer details
# ------------------------------------------------------------------------------------------------------------------
export CUSTOMER_NAME=<your company name>
export CUSTOMER_ICN=<your IBM Customer Number>
export CUSTOMER_ENVIRONMENT=<Set to `trial`, `poc`, or `production`>

# ------------------------------------------------------------------------------------------------------------------
# `OwnNamespace` installation mode:  leave INSTALL_MODE_NAMESPACE as it is.
# `AllNamespaces` installation mode: change to export INSTALL_MODE_NAMESPACE=openshift-operators
# ------------------------------------------------------------------------------------------------------------------
export INSTALL_MODE_NAMESPACE=${PROJECT_CP4AIOPS}

# ------------------------------------------------------------------------------------------------------------------
# Topology resource group terminology
# Specify `application` or `service` as the terminology to be used for collections of topology resource
# groups. The default is `application`.
# ------------------------------------------------------------------------------------------------------------------
export TOPOLOGY_TERMINOLOGY=application
```

You can update your deployment type after installation. For more information, see Updating the deployment type.

If you need help with deciding on the values to set for these environment variables, see the following topics.

- LOG_ANOMALY: Incremental adoption
- CP4AIOPS_SIZE: Sizing
- SECURE_TUNNEL: Secure Tunnel
- INSTALL_MODE_NAMESPACE: Operator installation mode

Note: You can set a different value for $PROJECT_CP4AIOPS, $CP4AIOPS_NAME if you want. However, you must not use the **default**, **kube-system**, **kube-public**, **openshift-node**, **openshift-infra**, or **openshift** projects (namespaces) for $PROJECT_CP4AIOPS. This is because IBM Cloud Pak for AIOps uses Security Context Constraints (SCC), and SCCs cannot be assigned to pods created in one of the default Red Hat OpenShift projects (namespaces).

Run the following command to source your script and set the environment variables:

```
. ./waiops_var.sh
```

5.2 Create the catalog sources

1. Run the following command to create the catalog sources for IBM Cloud Pak for AIOps and IBM Cloud Pak® foundational services Cert Manager and License Service in the *openshift-marketplace* namespace.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ${CATALOG_SRC_CP4AIOPS}
  namespace: openshift-marketplace
spec:
  displayName: ${CATALOG_SRC_CP4AIOPS}
  publisher: IBM Content
  sourceType: grpc
  image:
icr.io/cpopen/${CATALOG_SRC_CP4AIOPS}@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cert-manager-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cert-manager
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-cert-manager-operator-
catalog@sha256:c41e4d3314fac0d2cf5f08e7db85801cb2098d37d0aa8104a347e9e82526e914
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-licensing-catalog
  namespace: openshift-marketplace
spec:
  displayName: IBM License Service Catalog
  publisher: IBM
  sourceType: grpc
```

```
  image: icr.io/cpopen/ibm-licensing-catalog@sha256:9669ed5ba26ef32ad36a6784b2658553c00ac2a89cf4e9caddadf7bf46c1592e
EOF
```

2. Verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* **CatalogSource** objects are in the output that is returned by the following command:

```
oc get CatalogSources -n openshift-marketplace
```

Example output:

```
oc get CatalogSources -n openshift-marketplace
NAME                    DISPLAY                       TYPE   PUBLISHER   AGE
ibm-aiops-catalog       ibm-aiops-catalog             grpc   IBM         2m
ibm-cert-manager-catalog ibm-cert-manager             grpc   IBM         2m
ibm-licensing-catalog    IBM License Service Catalog  grpc   IBM         2m
```

5.3 Create a custom project (namespace)

Run the following command to create a project (namespace) to deploy IBM Cloud Pak for AIOps into.

```
oc create namespace ${PROJECT_CP4AIOPS}
```

5.4. Configure usage data collection

To help the development of IBM Cloud Pak for AIOps, daily aggregated usage data is collected to analyse how IBM Cloud Pak for AIOps is used. The collection of usage data is enabled by default, but can be disabled. Usage data is collected by the **cp4waiops-metricsprocessor** pod, and stored in the **cp4waiops-metricsprocessor** pod's logs. This usage data is sent to IBM when MustGather output is sent to IBM, as the MustGather includes the output from the **cp4waiops-metricsprocessor** pod's logs. The usage data is then sent to and stored in IBM controlled GDPR-compliant systems. The usage data that is collected is numeric, or is about the deployment type and platform. It does not include email addresses, passwords, or specific details. Only the following data is collected:

- Current number of applications
- Current number of alerts (all severities aggregated)
- Current number of incidents (all priorities aggregated)
- Current number of policies (includes predefined and user created)
- Current number of runbooks run since installation
- Current number of integrations of each type (For example ServiceNow, Instana, Falcon Logscale)
- Secure tunnel enablement: whether *connection* (which controls whether you can create a secure tunnel) is enabled in the *Installation* custom resource
- Deployment type: base deployment or extended deployment
- Deployment platform: Red Hat® OpenShift® Container Platform or Linux®

Configuring the collection of usage data

If you do not want to disable the collection of usage data, run the following command to configure the usage data with your customer details.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME} --
from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT}
```

Important: Usage data without your customer details is still collected even if you do not create this secret. If you do not want any usage data collected, then you must run the command given in *Disabling the collection of usage data*.

Disabling the collection of usage data

If you want to disable the collection of usage data, run the following command.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME} --
from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT} --from-
literal=enableCollection=false
```

Note: You can update your usage data collection preferences after installation. For more information, see Updating usage data collection preferences.

5.5 Install Cert Manager

Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

1. Run the following command to create the resource definitions that you need:

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Namespace
metadata:
  name: ibm-cert-manager
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-cert-manager-operator-group
  namespace: ibm-cert-manager
---
```

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-cert-manager-operator
  namespace: ibm-cert-manager
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-cert-manager-operator
  source: ibm-cert-manager-catalog
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-cert-manager get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

   ```
   NAME                                          READY   STATUS    RESTARTS   AGE
   cert-manager-cainjector-674854c49d-vstq4      1/1     Running   0          8d
   cert-manager-controller-646d4bd6fd-zwmqm      1/1     Running   0          8d
   cert-manager-webhook-8598787c8-s41kt          1/1     Running   0          8d
   ibm-cert-manager-operator-c96957695-dkxnm     1/1     Running   0          8d
   ```

5.6 Install the License Service

Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

1. Run the following command to create the resource definitions that you need:

   ```
   cat << EOF | oc apply -f -
   apiVersion: v1
   kind: Namespace
   metadata:
     name: ibm-licensing
   ---
   apiVersion: operators.coreos.com/v1
   kind: OperatorGroup
   metadata:
     name: ibm-licensing-operator-group
     namespace: ibm-licensing
   spec:
     targetNamespaces:
     - ibm-licensing
   ---
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: ibm-licensing-operator-app
     namespace: ibm-licensing
   spec:
     channel: v4.2
     installPlanApproval: Automatic
     name: ibm-licensing-operator-app
     source: ibm-licensing-catalog
     sourceNamespace: openshift-marketplace
   EOF
   ```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-licensing get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services License Service installation:

   ```
   NAME                                              READY   STATUS    RESTARTS   AGE
   ibm-licensing-operator-db4cd746c-xzmlf            1/1     Running   0          8d
   ibm-licensing-service-instance-596b99588f-76cc5   1/1     Running   0          8d
   ```

For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

5.7 Verify cluster readiness

Run the prerequisite checker script that you downloaded in step 1.1 Download documentation and scripts for offline access to verify whether your Red Hat OpenShift cluster is correctly set up for an IBM Cloud Pak for AIOps installation.

Run the script with the following command:

```
./prereq.sh -n ${PROJECT_CP4AIOPS}
```

Important: If you are installing on a multi-zone cluster, then also specify the `-m` flag to assess whether there are sufficient resources to withstand a zone outage.

Example output:

```
# ./prereq.sh -n cp4aiops

[INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

CLI: oc

[INFO] ================================Platform Version Check================================

```

5.8 Install the operator

For more information about installing operators, see Adding Operators to a cluster in the Red Hat OpenShift documentation.

For more information about the operators which are installed with IBM Cloud Pak for AIOps, see Operator Details.

1. Create an OperatorGroup.

   Important: Skip this step if you are installing using the 'All Namespaces' installation mode. Check that you set `INSTALL_MODE_NAMESPACE` correctly in step 5.2, and proceed to the next step, Install the IBM Cloud Pak for AIOps operator.

   If you are installing using the 'OwnNamespace' installation mode, then you must create an operator group in your custom project (namespace), or the IBM Cloud Pak for AIOps operator will not install. There might be an operator group for managing a namespace for given APIs. If there is an operator group for the namespace, do not create a second one.

Create the Operator group by running the following command:

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: cp4aiops-operator-group
  namespace: ${PROJECT_CP4AIOPS}
spec:
  targetNamespaces:
    - "${PROJECT_CP4AIOPS}"
EOF
```

2. Install the IBM Cloud Pak for AIOps operator.

   Run the following command.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-aiops-orchestrator
  namespace: $INSTALL_MODE_NAMESPACE
spec:
  channel: v4.8
  installPlanApproval: Automatic
  name: ibm-aiops-orchestrator
  source: ${CATALOG_SRC_CP4AIOPS}
  sourceNamespace: openshift-marketplace
EOF
```

   Warning: installPlanApproval must not be changed to *Manual*. Manual approval, which requires the manual review and approval of the generated InstallPlans, is not supported. Incorrect timing or ordering of manual approvals of InstallPlans can result in a failed installation.

3. After a few minutes, the IBM Cloud Pak for AIOps operator is installed. Verify that the all of the components have a state of **Succeeded** by running the following command:

```
oc get csv -n ${INSTALL_MODE_NAMESPACE} | egrep "ibm-aiops-orchestrator"
```

   Example output:

```
$ oc get csv -n ${INSTALL_MODE_NAMESPACE} | egrep "ibm-aiops-orchestrator"
ibm-aiops-orchestrator.v4.8.0          IBM Cloud Pak for AIOps                4.8.0   Succeeded
```

5.9 Install IBM Cloud Pak for AIOps

Create an instance of the IBM Cloud Pak for AIOps custom resource. A maximum of one IBM Cloud Pak for AIOps custom resource is allowed per cluster.

1. Use one of the following YAML codeblocks to create an instance of the IBM Cloud Pak for AIOps custom resource, depending on whether you are installing on a multi-zone cluster.

   Installing on a non multi-zone cluster:

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ${CP4AIOPS_NAME}
  namespace: ${PROJECT_CP4AIOPS}
spec:
  size: ${CP4AIOPS_SIZE}
  storageClass: ${STG_CLASS}
  storageClassLargeBlock: ${STG_CLASS_BLOCK}
  imagePullSecret:
  topologyModel: ${TOPOLOGY_TERMINOLOGY}
  license:
    accept: ${ACCEPT_LICENSE}
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: ${SECURE_TUNNEL}
  - name: logAnomalyDetection
    enabled: ${LOG_ANOMALY}
EOF
```

   Installing on a multi-zone cluster:

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ${CP4AIOPS_NAME}
  namespace: ${PROJECT_CP4AIOPS}
spec:
```

```
  size: ${CP4AIOPS_SIZE}
  storageClass: ${STG_CLASS}
  storageClassLargeBlock: ${STG_CLASS_BLOCK}
  imagePullSecret:
  topologyModel: ${TOPOLOGY_TERMINOLOGY}
  license:
    accept: ${ACCEPT_LICENSE}
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: ${SECURE_TUNNEL}
  - name: logAnomalyDetection
    enabled: ${LOG_ANOMALY}
  zones:
  - name: <zone_name1>
  - name: <zone_name2>
  - name: <zone_name3>
EOF
```

Where **<zone_name1>**, **<zone_name2>**, and **<zone_name3>** exactly match the zone labels that you applied to each of your nodes in step 1a of Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA).

Warning: The pakModules **aiopsFoundation**, **applicationManager**, and **aiManager** must be enabled as in the preceding YAML. Do not change these values to false.

2. Verify your installation.

   Run the following command to check that the **PHASE** of your installation is **Updating**.

   ```
   oc get installations.orchestrator.aiops.ibm.com -n ${PROJECT_CP4AIOPS}
   ```

   Example output:

   ```
   NAME           PHASE     LICENSE    STORAGECLASS    STORAGECLASSLARGEBLOCK    AGE
   ibm-cp-aiops   Updating  Accepted   rook-cephfs     rook-ceph-block           3m
   ```

   It takes around 60-90 minutes for the installation to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **PHASE** of your installation changes to **Running**. If your installation phase does not change to **Running**, then use the following command to find out which components are not ready:

   ```
   oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'Not Ready'
   ```

   Example output:

   ```
   lifecycleservice: Not Ready
   zenservice: Not Ready
   ```

   To see details about why a component is **Not Ready** run the following command, where **<component>** is the component that is not ready, for example **zenservice**.

   ```
   oc get <component> -o yaml -n ${PROJECT_CP4AIOPS}
   ```

   (Optional) If you downloaded the status checker script earlier in step 1.1 Download documentation and scripts for offline access, then you can also run this script to see information about the status of your deployment.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

5.10 Create an EgressFirewall

There is no egress firewall policy defined when you install IBM Cloud Pak for AIOps, so outgoing traffic from workload pods to the internal and external network is unrestricted.

To create a more secure environment, use the following steps.

1. Create an **EgressFirewall** on your Red Hat OpenShift cluster to limit egress from the IBM Cloud Pak for AIOps project (namespace).

   For more information about creating an **EgressFirewall**, see Configuring an egress firewall for a project.

   Note: You can have only one **EgressFirewall** per project/namespace.

2. Configure exceptions to the **EgressFirewall**.

   Edit your **EgressFirewall** to add exceptions for the following IBM Cloud Pak for AIOps components that have egress dependencies, otherwise these IBM Cloud Pak for AIOps components fail when they attempt egress.

   1. Allow egress to any external services, such as the following integrations:
      - Kubernetes
      - GitHub
      - Microsoft® Teams
      - ServiceNow

- Slack
- VMware® vCenter

2. Configure your **EgressFirewall** to allow traffic for your GitHub, Kubernetes, ServiceNow, and VMware vCenter integrations.

   Edit your **EgressFirewall** to allow or deny egress, as in the following example:

```
kind: EgressFirewall
metadata:
  name: default
spec:
  egress:
  - type: Allow
    to:
      cidrSelector: <1.2.3.0/24>
  - type: Allow
    to:
      dnsName: <www.github.com>
  - type: Allow
    to:
      dnsName: <www.developer.kubernetes.com>
  - type: Allow
    to:
      dnsName: <www.developer.servicenow.com>
  - type: Allow
    to:
      dnsName: <www.developer.vcenter.com>
  - type: Deny
    to:
      cidrSelector: <0.0.0.0/0>
```

   Substitute values for `dnsName` and `cidrSelector` that are the DNS names and addresses of your GitHub, Kubernetes, ServiceNow, or VMware vCenter sources.

5.11 Access the Cloud Pak for AIOps console

After you successfully install IBM Cloud Pak for AIOps, get the URL for accessing the Cloud Pak for AIOps console.

1. Use the following command to get the URL to access the Cloud Pak for AIOps console:

   ```
   oc get route -n ${PROJECT_CP4AIOPS} cpd -o jsonpath='{.spec.host}'
   ```

   The following output is a sample output:

   ```
   cpd-cp4aiops.apps.mycluster.mydomain
   ```

   Based on the sample output, your console URL would be **https://cpd-cp4aiops.apps.mycluster.mydomain**

2. Enter the URL in your browser to open the Cloud Pak for AIOps console. Log in with your username and password.

Find the IBM Cloud Pak for AIOps console username and password

The default username to access the Cloud Pak for AIOps console is **admin**. You can check the default username and their password with the following commands.

Note: This information is for the **IBM provided credentials (admin only)** authentication type.

1. Find the default username.

   ```
   oc -n ${PROJECT_CP4AIOPS} get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_username}' | base64 -d
   && echo
   ```

2. Get the password for the **admin** username.

   ```
   oc -n ${PROJECT_CP4AIOPS} get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d
   ```

   The following extract shows a sample output:

   ```
   EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA
   ```

   Based on the sample output, your password would be **EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA**.

Important: You can change this default password at any time. For more information, see Changing the cluster administrator password.

What to do next

- Define integrations and applications with Defining.
- You can integrate with IBM Cognos® Analytics. For more information, see Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps.
- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.
- Familiarize yourself with backup and restore procedures. It is recommended that you take regular backups of your IBM Cloud Pak for AIOps deployment. For more information, see Backup and restore.
- For more information about health checks and monitoring, see Health checks and monitoring.

Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline) using a portable device

If your cluster is not connected to the internet, you can deploy an installation of IBM Cloud Pak® for AIOps on your Red Hat® OpenShift® Container Platform cluster by using a portable compute device such as a laptop, or a portable storage device such as a USB device.

In this scenario, your air-gapped (offline) environment has a target registry, and a Red Hat OpenShift cluster on which IBM Cloud Pak for AIOps is to be installed. IBM Cloud Pak for AIOps images are mirrored from the internet to a file system on a portable compute device or a portable storage device. The portable device is then disconnected from the internet and connected in the offline environment, where the images are loaded to the target registry. IBM Cloud Pak for AIOps can then be installed in the offline environment by using the target registry.

Before you begin

- You must know whether you are deploying a base deployment or a extended deployment of IBM Cloud Pak for AIOps. For more information, see Incremental adoption.
- Review the Planning section. Your environment must meet the system requirements.
- Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).
- The following commands must be run as a root user or by a user with sudo access: `yum install podman` and `podman login`. The rest of the procedure can be run as a non-root user.
- If you require details about the permissions that the IBM Cloud Pak for AIOps operators need, see Permissions (IBM Cloud Pak for AIOps).
- A user with `cluster-admin` privileges is needed for the following operations:
  - Install Cert Manager
  - Install the License Service
  - Create a custom project
  - Configure the cluster
  - Create the catalog source
  - Create an OperatorGroup

Important: If IBM Sales representatives and Business Partners supplied you with a custom profile ConfigMap to customize your deployment, then you must follow their instructions to apply it during installation. The custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. For more information about custom sizing, see Custom sizing.

The following procedure is based on an Red Hat OpenShift 4.17 environment and includes links for that version. If your environment uses a different supported version of Red Hat OpenShift, ensure that you follow the Red Hat OpenShift documentation for that version.

Installation procedure

1. Set up the mirroring environment
2. Download the CASE
3. Mirror images
4. Configure storage
5. Install IBM Cloud Pak for AIOps

1. Set up the mirroring environment

Prerequisites

Allow access to the following sites and ports:

Table 1. Sites and ports that must be accessible

Site	Description

`icr.io`
`cp.icr.io`
`dd0.icr.io`
`dd2.icr.io`
`dd4.icr.io`
`dd6.icr.io`
	Allow access to these hosts on port 443 to enable access to the `IBM Cloud Container Registry`, CASE OCI artifact, and IBM Cloud Pak® foundational services catalog source.

`dd1-icr.ibm-zh.com`
`dd3-icr.ibm-zh.com`
`dd5-icr.ibm-zh.com`
`dd7-icr.ibm-zh.com`
	If you are located in China, also allow access to these hosts on port 443.

`github.com`	Github houses CASE files, IBM Cloud Pak tools and scripts.
`redhat.com`	Red Hat OpenShift registries that are required for Red Hat OpenShift, and for Red Hat OpenShift upgrades.

1.1 Download documentation and scripts for offline access

Download the following documentation and scripts that you might need to access during your IBM Cloud Pak for AIOps installation, and copy them to your air-gapped environment.

1. IBM Cloud Pak for AIOps 4.8.0 documentation

Download the Cloud Pak for AIOps 4.8.0 PDF (this documentation) so that you can access it offline.

2. IBM Cloud Pak for AIOps 4.8.0 scripts

   - The prerequisite checker script verifies whether your Red Hat OpenShift cluster is correctly set up for a IBM Cloud Pak for AIOps installation. You will need to run this script in step 5.7 Verify cluster readiness. Download this script from github.com/IBM.
   - An uninstall script can be downloaded from github.com/IBM.
   - (Optional) The status checker script can be used in step 5.9 Install IBM Cloud Pak for AIOps to give information about the status of your deployment. The use of this script is optional, as status can be found directly from the **`ibm-aiops-orchestrator`** custom resource. This script can be downloaded from github.com/IBM.

3. Red Hat OpenShift documentation

   The Red Hat OpenShift documentation can be downloaded for offline access from Red Hat. The **`Security and compliance`**, **`Installing`**, **`CLI Tools`**, **`Images`**, and **`Operators`** sections are referenced by this documentation.

1.2 Install and configure Red Hat OpenShift

IBM Cloud Pak for AIOps requires Red Hat OpenShift to be installed and running on your target cluster. You must have administrative access to your Red Hat OpenShift cluster.

For more information about the supported versions of Red Hat OpenShift, see Supported Red Hat OpenShift Container Platform versions.

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation. Information about installing a cluster in a restricted network is given in Mirroring images for a disconnected installation.

2. Install the Red Hat OpenShift command line interface (**`oc`**) on your cluster's boot node and run **`oc login`**. For more information, see the instructions in Getting started with the Red Hat OpenShift CLI.

3. Ensure that the clocks on your Red Hat OpenShift cluster are synchronized. Each Red Hat OpenShift node in the cluster must have access to an NTP server. Red Hat OpenShift nodes use NTP to synchronize their clocks. IBM Cloud Pak for AIOps runs on Red Hat OpenShift and also has this requirement. Discrepancies between the clocks on the Red Hat OpenShift nodes can cause IBM Cloud Pak for AIOps to experience operational issues. See the Red Hat OpenShift documentation for information about how to use a **`MachineConfig`** custom resource to configure chrony to connect to your NTP servers.

4. Optionally configure a custom certificate for IBM Cloud Pak for AIOps to use. You can use either of the following methods:

   - Configure a custom certificate for the Red Hat OpenShift cluster. Follow the instructions in the Red Hat OpenShift documentation Replacing the default ingress certificate. Then, deploy the signing CA certificate into the cluster by following the instructions in the Red Hat OpenShift documentation Replacing the CA Bundle certificate.
   - If you would like to use a custom certificate for IBM Cloud Pak for AIOps only, then after installation is complete follow the instructions in Using a custom certificate.

1.3 Set up a target registry

You must have a local Docker type production-grade registry available in the air-gapped environment to store the IBM Cloud Pak for AIOps images in. The registry must meet the following requirements:

- supports Docker Manifest V2, Schema 2.
- supports multi-architecture images.
- is accessible from the Red Hat OpenShift cluster nodes.
- allows path separators in the image name.
- you have the username and password for a user who can read from and write to the registry.
- must have 140 GB of storage to hold all of the software that is to be transferred to the target registry.

If you do not already have a suitable production-grade registry available, then you must install and configure one. For more information, see About the mirror registry in the Red Hat OpenShift documentation.

Important: Do not use the Red Hat OpenShift image registry as your target registry. The Red Hat OpenShift registry does not support multi-architecture images or path separators in the image name.

1.4 Prepare a host

Prepare a portable compute device, or if you are using a portable storage device then a connected compute device, as follows.

You must be able to connect your host to the internet. Your host must be on a Linux® x86_64 or Mac platform with any operating system that the IBM Cloud Pak CLI and the Red Hat OpenShift CLI support. If you are on a Windows® platform, you must run the actions in a Linux® x86_64 VM or from a Windows Subsystem for Linux® (WSL) terminal.

Your portable device and any intermediary devices must have 140 GB of storage to hold all the software that is to be transferred to the local target registry.

Complete the following steps on your host.

1. Install Podman.

   To install Podman, see the Podman Installation Instructions.

   Note: Docker is not shipped or supported for Red Hat Enterprise Linux (RHEL) 8. The Podman container engine replaced docker as the preferred, maintained, and supported container runtime of choice for Red Hat Enterprise Linux 8 systems. For more information, see Running containers without Docker in the Red Hat documentation.

2. Install the Red Hat OpenShift CLI tool, **`oc`**.

`oc` is required for Red Hat OpenShift management. For more information, see Getting started with the Red Hat OpenShift CLI in the Red Hat OpenShift documentation.

1.5 Install the IBM Catalog Management Plug-in for IBM Cloud Pak®

The IBM Catalog Management Plug-in for IBM Cloud Pak (`ibm-pak-plugin`) is used for the deployment of IBM Cloud Paks® in a disconnected environment. It simplifies the process for discovering required IBM product images and uses standard tools for registry and cluster access. The `ibm-pak-plugin` also extends the Red Hat OpenShift CLI (`oc`) capability to streamline the process of delivering installation images to the IBM Cloud Pak in an air-gapped environment.

1. Download and install the most recent version of the IBM Catalog Management Plug-in for IBM Cloud Pak for your host operating system from github.com/IBM.
2. Run the following command to extract the files.

   ```
   tar -xf oc-ibm_pak-linux-amd64.tar.gz
   ```

3. Run the following command to move the file to the `/usr/local/bin` directory.

   ```
   mv oc-ibm_pak-linux-amd64 /usr/local/bin/oc-ibm_pak
   ```

   Note: If you are installing as a non-root user, you must use sudo.

4. Confirm that `ibm-pak-plugin` is installed by running the following command.

   ```
   oc ibm-pak --help
   ```

   Expected result: The `ibm-pak-plugin` usage is displayed.

2. Download the CASE

Set environment variables on the portable device, and connect it to the internet so that you can download the IBM Cloud Pak for AIOps CASE files.

Note: Save a copy of your environment variable values to a file that you can use as a reference when you are completing your air-gapped installation tasks.

1. Create the following environment variables.

   ```
   export CASE_NAME=ibm-cp-waiops
   export CASE_VERSION=1.14.0
   export CASE_INVENTORY_SETUP=cpwaiopsSetup
   export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
   export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   export TARGET_REGISTRY_USER=<username>
   export TARGET_REGISTRY_PASSWORD=<password>
   ```

   The target registry is the registry where the IBM Cloud Pak for AIOps images are mirrored to, and accessed from by the Red Hat OpenShift cluster, as setup in 1.3 Set up a target registry

   If your portable device must connect to the internet through a proxy, then also set the following environment variables.

   ```
   export https_proxy=http://proxy-server-hostname:port
   export http_proxy=http://proxy-server-hostname:port
   ```

2. Connect your portable device to the internet and disconnect it from the air-gapped environment.
3. Download the IBM Cloud Pak for AIOps installer and image inventory to your portable device.

   ```
   oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
   ```

   The CASE is downloaded to `~/.ibm-pak/data/cases/$CASE_NAME/$CASE_VERSION`. The logs files are available at ~/.ibm-pak/logs/oc-ibm_pak.log.

   Note: If you do not specify the CASE version, then the latest CASE is downloaded. The root directory that is used by the `ibm-pak-plugin` is `~/.ibm-pak`. If required, the root directory can be configured by setting the `IBMPAK_HOME` environment variable.

3. Mirror images

Complete the following steps to mirror the IBM Cloud Pak for AIOps, IBM Cloud Pak foundational services Cert Manager, and IBM Cloud Pak foundational services License Service images from the internet to the file system on your portable device, and then from the file system to the target registry in the air-gapped environment.

3.1. Generate mirror manifests

Run the following command to generate mirror manifests to be used when mirroring the images to the target registry.

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} file://cpfs --version ${CASE_VERSION} --filter ibm_es_opensearch --final-registry ${TARGET_REGISTRY}/cpfs
```

Table 2. Parameter description

Argument	Description
`file://cpfs`	Specifies the path extension where images are mirrored to. Images are mirrored to `$IMAGE_PATH/cpfs` when the `oc image mirror` command is run with `images-mapping-to-filesystem.txt`. For more information, see Mirror the images to the file system.

Argument	Description
`$TARGET_REGISTRY/cpfs`	This argument generates an image-mapping file that is used by the `oc image mirror` commands to mirror images to the `TARGET_REGISTRY` at namespace `cpfs`. For example, if the CASE you are installing needs the image, `quay.io/opencloudio/ibm-events-kafka-2.6.0@sha256:10d422dddd29ff19c87066fc6510eee05f5fa4ff608b87a06e898b3b6a3a13c7`, then its final URL in your target registry will be `$TARGET_REGISTRY/cpfs/opencloudio/ibm-events-kafka-2.6.0`. Note the new namespace of `cpfs` in the URL. The namespace path can be multi level if your target registry supports it.

The command generates the following files at `~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION`:

- images-mapping-to-filesystem.txt
- images-mapping-from-filesystem.txt
- image-content-source-policy.yaml

3.2. Authenticate with the IBM Entitled Registry

Log in to the IBM Entitled Registry to generate an authentication file containing the IBM Entitled Registry credentials, and then create an environment variable that has the location of the authentication file. This file is used later to enable the `oc image mirror` command to pull the images from the IBM Entitled Registry.

1. Get the authentication credentials for the IBM Entitled Registry.
    1. To obtain the entitlement key that is assigned to your IBMid, log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.
    2. In the *Entitlement keys* section, select **Copy key** to copy the entitlement key.
2. Run the following command to create an environment variable that contains your entitlement key.

    ```
    export ENTITLED_REGISTRY_PASSWORD=<key>
    ```

    Where `<key>` is the entitlement key that you copied in the previous step.
3. Store the authentication credentials for the IBM Entitled Registry.

    Run the following commands:

    ```
    podman login cp.icr.io -u cp -p ${ENTITLED_REGISTRY_PASSWORD}
    export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
    unset ENTITLED_REGISTRY_PASSWORD
    ```

    Note: The authentication file is usually at `${XDG_RUNTIME_DIR}/containers/auth.json`. For more information, see the Options section in the Podman documentation.

3.3. Mirror the images to the file system

Complete these steps to mirror the images from the internet to a file system on your portable device.

1. Create an environment variable to store the location of the file system where the images are to be stored.

    ```
    export IMAGE_PATH=<image-path>
    ```

    Where `<image-path>` is the directory where you want the images to be stored.
2. Run the following command to mirror the images from the IBM Entitled Registry to the file system.

    ```
    nohup oc image mirror \
    -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/images-mapping-to-filesystem.txt \
    -a ${REGISTRY_AUTH_FILE} \
    --filter-by-os '.*' \
    --insecure \
    --skip-multiple-scopes \
    --dir "${IMAGE_PATH}" \
    --max-per-registry=1 > my-mirror-progress.txt 2>&1 &
    ```

    The UNIX® command `nohup` is used to ensure that the mirroring process continues even if there is a loss of network connection, and redirection of output to a file provides improved monitoring and error visibility.

    Run the following command if you want to see the progress of the mirroring:

    ```
    tail -f my-mirror-progress.txt
    ```

    Note: If an error occurs during mirroring, the mirror command can be rerun.

3.4 Setup the file system in the air-gapped environment

1. Copy files to the air-gapped environment (portable storage device only)

    If you are using a portable storage device, you must copy the files from the portable storage device to a local compute device in the air-gapped environment that has access to the target registry. If you are using a portable compute device, then these items are already present, and you can proceed to the next step.

    Copy the following items to your local compute device:

    - the file system located at $IMAGE_PATH, which you specified earlier
    - `~/.ibm-pak` directory
2. Disconnect the device that has your file system, (the portable compute device or the local compute device) from the internet and connect it to the air-gapped environment.
3. Ensure that environment variables are set on the device in the air-gapped environment that has access to the target registry.

If you are using a portable storage device, then set the following environment variables on your local compute device within the air-gapped environment.

If you are using a portable compute device that you have restarted since mirroring the images, then your environment variables will have been lost and you will need to set the following environment variables on your portable compute device again.

```
export CASE_NAME=ibm-cp-waiops
export CASE_VERSION=1.14.0
export CASE_INVENTORY_SETUP=cpwaiopsSetup
export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
export TARGET_REGISTRY=${TARGET_REGISTRY_HOST}:${TARGET_REGISTRY_PORT}
export TARGET_REGISTRY_USER=<username>
export TARGET_REGISTRY_PASSWORD=<password>
export IMAGE_PATH=<image_path>
```

3.5 Authenticate with the target registry

Authenticate with the target registry in the air-gapped environment that you are mirroring the images into.

Run the following commands:

```
podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD}
export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
```

Note: The authentication file is usually at **`${XDG_RUNTIME_DIR}/containers/auth.json`**. For more information, see the Options section in the Podman documentation.

3.6 Mirror the images to the target registry from the file system

Complete the steps in this section on the device that has your file system (the portable compute device or the local compute device) to copy the images from the file system to the $TARGET_REGISTRY. Your device with the file system must be connected to both the target registry and the Red Hat OpenShift cluster.

Run the following command to copy the images referenced in the **`images-mapping-from-filesystem.txt`** from the $IMAGE_PATH file system to the final target registry.

```
nohup oc image mirror \
-f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/images-mapping-from-filesystem.txt \
--from-dir "${IMAGE_PATH}" \
-a ${REGISTRY_AUTH_FILE} \
--filter-by-os '.*' \
--insecure  \
--skip-multiple-scopes \
--max-per-registry=1 > my-mirror-progress2.txt 2>&1 &
```

The UNIX command **`nohup`** is used to ensure that the mirroring process continues even if there is a loss of network connection, and redirection of output to a file provides improved monitoring and error visibility.

Run the following command if you want to see the progress of the mirroring:

```
tail -f my-mirror-progress2.txt
```

Note: If an error occurs during mirroring, the mirror command can be rerun.

3.7 Configure the cluster

1. Log in to your Red Hat OpenShift cluster.

   You can identify your specific **`oc login`** command by clicking the user menu in the upper left of the Red Hat OpenShift console, and then clicking **Copy Login Command**.

   Example:

   ```
   oc login <server> -u <cluster username> -p <cluster pass>
   ```

2. Update the global image pull secret for your Red Hat OpenShift cluster.

   Follow the steps in the Red Hat OpenShift documentation topic Updating the global cluster pull secret.

   These steps enable your cluster to have authentication credentials in place to pull images from your TARGET_REGISTRY as specified in the **`image-content-source-policy.yaml`**, which you will apply to your cluster in the next step.

3. Create the **`ImageContentSourcePolicy`**.

   Run the following command to create an ImageContentSourcePolicy (ICSP).

   ```
   oc apply -f  ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/image-content-source-policy.yaml
   ```

4. Verify that the **`ImageContentSourcePolicy`** resource is created.

   ```
   oc get imagecontentsourcepolicy
   ```

   Example output, showing a newly created **`ibm-cp-waiops`** ICSP.

   ```
   oc get imagecontentsourcepolicy
   NAME                        AGE
   ibm-cp-waiops               95s
   redhat-operator-index-0     5d18h
   ```

5. Verify your cluster node status.

```
oc get MachineConfigPool -w
```

Important: After the `ImageContentsourcePolicy` and global image pull secret are applied, the configuration of your nodes will be updated sequentially. Wait until all the `MachineConfigPools` are updated before proceeding to the next step.

6. (Optional) If you use an insecure registry, you must add the target registry to the cluster's `insecureRegistries` list.

```
oc patch image.config.openshift.io/cluster --type=merge \
-p '{"spec":{"registrySources":{"insecureRegistries":["'${TARGET_REGISTRY}'"]}}}'
```

4. Configure storage

The storage configuration must satisfy your sizing requirements. Two storage classes are needed for installing IBM Cloud Pak for AIOps. For more information, see Storage.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the `RWX-storage-class-name` in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

5. Install IBM Cloud Pak for AIOps

Now that the images are mirrored to your air-gapped environment, you can deploy IBM Cloud Pak for AIOps to that environment. To install IBM Cloud Pak for AIOps, complete the following steps.

- 5.1 Create environment variables
- 5.2 Create the catalog source
- 5.3 Create a custom project
- 5.4 Configure usage data collection
- 5.5 Install Cert Manager
- 5.6 Install the License Service
- 5.7 Verify cluster readiness
- 5.8 Install the operator
- 5.9 Install IBM Cloud Pak for AIOps
- 5.10 Create an EgressFirewall
- 5.11 Access the Cloud Pak for AIOps console

5.1 Create environment variables

Create and then source a shell script named *waiops_var.sh* that defines the environment variables which will be used to provide installation parameters for your deployment. Use the following codeblock as a template, replacing the brackets **< ... >** with values for your environment.

You can use the following table to find the values to set for your storage environment variables.

Table 3. Storage provider classes

Storage provider	RWX-storage-class-name	RWO-storage-class-name
IBM Cloud®	ibmc-block-gold	ibmc-block-gold
IBM Cloud® with OADP backup and restore	ibmc-file-gold-gid	ibmc-block-gold
Red Hat® OpenShift® Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
Red Hat® OpenShift® Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation	ocs-storagecluster-ceph-rbd	ocs-storagecluster-ceph-rbd
IBM Fusion Data Foundation with OADP backup and restore	ocs-storagecluster-cephfs	ocs-storagecluster-ceph-rbd
IBM Fusion Global Data Platform	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc	If you are using IBM Storage Fusion, use ibm-spectrum-scale-sc. If you are using IBM Storage Fusion HCI System, use ibm-storage-fusion-cp-sc
IBM Storage Scale Container Native	ibm-spectrum-scale-sc	ibm-spectrum-scale-sc
Portworx	px-csi-aiops	px-csi-aiops
Portworx (multi-zone HA)	px-csi-aiops-mz	px-csi-aiops-mz
AWS native storage	gp3-csi	gp3-csi
AWS native storage with OADP backup and restore	efs-sc	gp3-csi

```
#============================================================================================================
# Cloud Pak for AIOps installation variables
#============================================================================================================

export CP4AIOPS_NAME=ibm-cp-aiops
export CP4AIOPS_SIZE=large # Set to small if you only require a starter non-production deployment.
export SECURE_TUNNEL=false # Set to `true` to install Secure Tunnel, otherwise set to `false`.
export PROJECT_CP4AIOPS=cp4aiops
export ACCEPT_LICENSE=false # Set to `true` to agree to the license terms, otherwise install will fail.
export CATALOG_SRC_CP4AIOPS=ibm-aiops-catalog

# ------------------------------------------------------------------------------------------------------------
```

```
# Incremental adoption - set your deployment type.
# Set to `true` to install an extended deployment with log anomaly detection and ticket analysis capabilities
# Set to `false` to install a base deployment without log anomaly detection and ticket analysis capabilities
# ------------------------------------------------------------------------------------------------------------------
export LOG_ANOMALY=false

# ------------------------------------------------------------------------------------------------------------------
# Storage
# ------------------------------------------------------------------------------------------------------------------
export STG_CLASS=<RWX-storage-class-name>
export STG_CLASS_BLOCK=<RWO-storage-class-name>

# ------------------------------------------------------------------------------------------------------------------
# Your customer details
# ------------------------------------------------------------------------------------------------------------------
export CUSTOMER_NAME=<your company name>
export CUSTOMER_ICN=<your IBM Customer Number>
export CUSTOMER_ENVIRONMENT=<Set to `trial`, `poc`, or `production`>

# ------------------------------------------------------------------------------------------------------------------
# `OwnNamespace` installation mode:  leave INSTALL_MODE_NAMESPACE as it is.
# `AllNamespaces` installation mode: change to export INSTALL_MODE_NAMESPACE=openshift-operators
# ------------------------------------------------------------------------------------------------------------------
export INSTALL_MODE_NAMESPACE=${PROJECT_CP4AIOPS}

# ------------------------------------------------------------------------------------------------------------------
# Topology resource group terminology
# Specify `application` or `service` as the terminology to be used for collections of topology resource
# groups. The default is `application`.
# ------------------------------------------------------------------------------------------------------------------
export TOPOLOGY_TERMINOLOGY=application
```

If you need help with deciding on the values to set for these environment variables, see the following topics.

- LOG_ANOMALY: Incremental adoption
- CP4AIOPS_SIZE: Sizing
- SECURE_TUNNEL: Secure Tunnel
- INSTALL_MODE_NAMESPACE: Operator installation mode

You can update your deployment type after installation. For more information, see Updating the deployment type.

Note: You can set a different value for $PROJECT_CP4AIOPS and $CP4AIOPS_NAME if you want. However, you must not use the **default**, **kube-system**, **kube-public**, **openshift-node**, **openshift-infra**, or **openshift** projects (namespaces) for $PROJECT_CP4AIOPS. This is because IBM Cloud Pak for AIOps uses Security Context Constraints (SCC), and SCCs cannot be assigned to pods created in one of the default Red Hat OpenShift projects (namespaces).

Run the following command to source your script and set the environment variables:

```
. ./waiops_var.sh
```

5.2 Create the catalog sources

1. Run the following command to create the catalog sources for IBM Cloud Pak for AIOps and IBM Cloud Pak® foundational services Cert Manager and License Service in the *openshift-marketplace* namespace.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ${CATALOG_SRC_CP4AIOPS}
  namespace: openshift-marketplace
spec:
  displayName: ${CATALOG_SRC_CP4AIOPS}
  publisher: IBM Content
  sourceType: grpc
  image:
icr.io/cpopen/${CATALOG_SRC_CP4AIOPS}@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-cert-manager-catalog
  namespace: openshift-marketplace
spec:
  displayName: ibm-cert-manager
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-cert-manager-operator-
catalog@sha256:c41e4d3314fac0d2cf5f08e7db85801cb2098d37d0aa8104a347e9e82526e914
---
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ibm-licensing-catalog
  namespace: openshift-marketplace
spec:
  displayName: IBM License Service Catalog
  publisher: IBM
  sourceType: grpc
  image: icr.io/cpopen/ibm-licensing-catalog@sha256:9669ed5ba26ef32ad36a6784b2658553c00ac2a89cf4e9caddadf7bf46c1592e
EOF
```

2. Verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* **CatalogSource** objects are in the output that is returned by the following command:

```
oc get CatalogSources -n openshift-marketplace
```

Example output:

```
oc get CatalogSources -n openshift-marketplace
NAME                     DISPLAY                       TYPE   PUBLISHER   AGE
ibm-aiops-catalog        ibm-aiops-catalog             grpc   IBM         2m
ibm-cert-manager-catalog ibm-cert-manager              grpc   IBM         2m
ibm-licensing-catalog    IBM License Service Catalog   grpc   IBM         2m
```

5.3 Create a custom project (namespace)

Run the following command to create a project (namespace) to deploy IBM Cloud Pak for AIOps into.

```
oc create namespace ${PROJECT_CP4AIOPS}
```

5.4. Configure usage data collection

To help the development of IBM Cloud Pak for AIOps, daily aggregated usage data is collected to analyse how IBM Cloud Pak for AIOps is used. The collection of usage data is enabled by default, but can be disabled. Usage data is collected by the **cp4waiops-metricsprocessor** pod, and stored in the **cp4waiops-metricsprocessor** pod's logs. This usage data is sent to IBM when MustGather output is sent to IBM, as the MustGather includes the output from the **cp4waiops-metricsprocessor** pod's logs. The usage data is then sent to and stored in IBM controlled GDPR-compliant systems. The usage data that is collected is numeric, or is about the deployment type and platform. It does not include email addresses, passwords, or specific details. Only the following data is collected:

- Current number of applications
- Current number of alerts (all severities aggregated)
- Current number of incidents (all priorities aggregated)
- Current number of policies (includes predefined and user created)
- Current number of runbooks run since installation
- Current number of integrations of each type (For example ServiceNow, Instana, Falcon Logscale)
- Secure tunnel enablement: whether *connection* (which controls whether you can create a secure tunnel) is enabled in the *Installation* custom resource
- Deployment type: base deployment or extended deployment
- Deployment platform: Red Hat® OpenShift® Container Platform or Linux®

This usage data is sent to IBM only if the MustGather tool is run and sent to IBM. The MustGather includes the output from the **cp4waiops-metricsprocessor** pod's logs.

Configuring the collection of usage data

If you do not want to disable the collection of usage data, run the following command to configure the usage data with your customer details.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME} --
from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT}
```

Important: Usage data without your customer details is still collected even if you do not create this secret. If you do not want any usage data collected, then you must run the command given in *Disabling the collection of usage data*.

Disabling the collection of usage data

If you want to disable the collection of usage data, run the following command.

```
oc create secret generic aiops-metrics-processor -n ${PROJECT_CP4AIOPS} --from-literal=customerName=${CUSTOMER_NAME} --
from-literal=customerICN=${CUSTOMER_ICN} --from-literal=environment=${CUSTOMER_ENVIRONMENT} --from-
literal=enableCollection=false
```

Note: You can update your usage data collection preferences after installation. For more information, see Updating usage data collection preferences.

5.5 Install Cert Manager

Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

1. Run the following command to create the resource definitions that you need:

```
cat << EOF | oc apply -f -
apiVersion: v1
kind: Namespace
metadata:
  name: ibm-cert-manager
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: ibm-cert-manager-operator-group
  namespace: ibm-cert-manager
---
```

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-cert-manager-operator
  namespace: ibm-cert-manager
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-cert-manager-operator
  source: ibm-cert-manager-catalog
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-cert-manager get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

   ```
   NAME                                       READY   STATUS    RESTARTS   AGE
   cert-manager-cainjector-674854c49d-vstq4   1/1     Running   0          8d
   cert-manager-controller-646d4bd6fd-zwmqm   1/1     Running   0          8d
   cert-manager-webhook-8598787c8-s41kt       1/1     Running   0          8d
   ibm-cert-manager-operator-c96957695-dkxnm  1/1     Running   0          8d
   ```

5.6 Install the License Service

Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

1. Run the following command to create the resource definitions that you need:

   ```
   cat << EOF | oc apply -f -
   apiVersion: v1
   kind: Namespace
   metadata:
     name: ibm-licensing
   ---
   apiVersion: operators.coreos.com/v1
   kind: OperatorGroup
   metadata:
     name: ibm-licensing-operator-group
     namespace: ibm-licensing
   spec:
     targetNamespaces:
     - ibm-licensing
   ---
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: ibm-licensing-operator-app
     namespace: ibm-licensing
   spec:
     channel: v4.2
     installPlanApproval: Automatic
     name: ibm-licensing-operator-app
     source: ibm-licensing-catalog
     sourceNamespace: openshift-marketplace
   EOF
   ```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-licensing get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services License Service installation:

   ```
   NAME                                              READY   STATUS    RESTARTS   AGE
   ibm-licensing-operator-db4cd746c-xzmlf            1/1     Running   0          8d
   ibm-licensing-service-instance-596b99588f-76cc5   1/1     Running   0          8d
   ```

For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

5.7 Verify cluster readiness

Run the prerequisite checker script that you downloaded in step 1.1 Download documentation and scripts for offline access to verify whether your Red Hat OpenShift cluster is correctly set up for an IBM Cloud Pak for AIOps installation.

Run the script with the following command:

```
./prereq.sh -n ${PROJECT_CP4AIOPS}
```

Important: If you are installing on a multi-zone cluster, then also specify the `-m` flag to assess whether there are sufficient resources to withstand a zone outage.

Example output:

```
# ./prereq.sh -n cp4aiops

[INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

CLI: oc

[INFO] ================================Platform Version Check================================

```

5.8 Install the operator

For more information about installing operators, see Adding Operators to a cluster in the Red Hat OpenShift documentation.

For more information about the operators which are installed with IBM Cloud Pak for AIOps, see Operator Details.

1. Create an OperatorGroup.

   Important: Skip this step if you are installing using the 'All Namespaces' installation mode. Check that you set **`INSTALL_MODE_NAMESPACE`** correctly in step 5.2, and proceed to the next step, Install the IBM Cloud Pak for AIOps operator.

   If you are installing using the 'OwnNamespace' installation mode, then you must create an operator group in your custom project (namespace), or the IBM Cloud Pak for AIOps operator will not install. There might be an operator group for managing a namespace for given APIs. If there is an operator group for the namespace, do not create a second one.

Create the Operator group by running the following command:

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: cp4aiops-operator-group
  namespace: ${PROJECT_CP4AIOPS}
spec:
  targetNamespaces:
    - "${PROJECT_CP4AIOPS}"
EOF
```

2. Install the IBM Cloud Pak for AIOps operator.

   Run the following command.

```
cat << EOF | oc apply -f -
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-aiops-orchestrator
  namespace: $INSTALL_MODE_NAMESPACE
spec:
  channel: v4.8
  installPlanApproval: Automatic
  name: ibm-aiops-orchestrator
  source: ${CATALOG_SRC_CP4AIOPS}
  sourceNamespace: openshift-marketplace
EOF
```

   Warning: installPlanApproval must not be changed to *Manual*. Manual approval, which requires the manual review and approval of the generated InstallPlans, is not supported. Incorrect timing or ordering of manual approvals of InstallPlans can result in a failed installation.

3. After a few minutes, the IBM Cloud Pak for AIOps operator is installed. Verify that the all of the components have a state of **Succeeded** by running the following command:

```
oc get csv -n ${INSTALL_MODE_NAMESPACE} | egrep "ibm-aiops-orchestrator"
```

   Example output:

```
$ oc get csv -n ${INSTALL_MODE_NAMESPACE} | egrep "ibm-aiops-orchestrator"
ibm-aiops-orchestrator.v4.8.0          IBM Cloud Pak for AIOps                4.8.0   Succeeded
```

5.9 Install IBM Cloud Pak for AIOps

Create an instance of the IBM Cloud Pak for AIOps custom resource. A maximum of one IBM Cloud Pak for AIOps custom resource is allowed per cluster.

1. Use one of the following YAML codeblocks to create an instance of the IBM Cloud Pak for AIOps custom resource, depending on whether you are installing on a multi-zone cluster.

   Installing on a non multi-zone cluster:

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ${CP4AIOPS_NAME}
  namespace: ${PROJECT_CP4AIOPS}
spec:
  size: ${CP4AIOPS_SIZE}
  storageClass: ${STG_CLASS}
  storageClassLargeBlock: ${STG_CLASS_BLOCK}
  imagePullSecret:
  topologyModel: ${TOPOLOGY_TERMINOLOGY}
  license:
    accept: ${ACCEPT_LICENSE}
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: ${SECURE_TUNNEL}
  - name: logAnomalyDetection
    enabled: ${LOG_ANOMALY}
EOF
```

   Installing on a multi-zone cluster:

```
cat << EOF | oc apply -f -
apiVersion: orchestrator.aiops.ibm.com/v1alpha1
kind: Installation
metadata:
  name: ${CP4AIOPS_NAME}
  namespace: ${PROJECT_CP4AIOPS}
spec:
```

```
  size: ${CP4AIOPS_SIZE}
  storageClass: ${STG_CLASS}
  storageClassLargeBlock: ${STG_CLASS_BLOCK}
  imagePullSecret:
  topologyModel: ${TOPOLOGY_TERMINOLOGY}
  license:
    accept: ${ACCEPT_LICENSE}
  pakModules:
  - name: aiopsFoundation
    enabled: true
  - name: applicationManager
    enabled: true
  - name: aiManager
    enabled: true
  - name: connection
    enabled: ${SECURE_TUNNEL}
  - name: logAnomalyDetection
    enabled: ${LOG_ANOMALY}
  zones:
  - name: <zone_name1>
  - name: <zone_name2>
  - name: <zone_name3>
EOF
```

Where **<zone_name1>**, **<zone_name2>**, and **<zone_name3>** exactly match the zone labels that you applied to each of your nodes in step 1a of Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA).

Warning: The pakModules **aiopsFoundation**, **applicationManager**, and **aiManager** must be enabled as in the preceding YAML. Do not change these values to false.

2. Verify your installation.

   Run the following command to check that the **PHASE** of your installation is **Updating**.

   ```
   oc get installations.orchestrator.aiops.ibm.com -n ${PROJECT_CP4AIOPS}
   ```

   Example output:

   ```
   NAME                  PHASE     LICENSE    STORAGECLASS    STORAGECLASSLARGEBLOCK   AGE
   ibm-cp-aiops          Updating  Accepted   rook-cephfs     rook-ceph-block          3m
   ```

   It takes around 60-90 minutes for the installation to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **PHASE** of your installation changes to **Running**. If your installation phase does not change to **Running**, then use the following command to find out which components are not ready:

   ```
   oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'Not Ready'
   ```

   Example output:

   ```
   lifecycleservice: Not Ready
   zenservice: Not Ready
   ```

   To see details about why a component is **Not Ready** run the following command, where **<component>** is the component that is not ready, for example **zenservice**.

   ```
   oc get <component> -o yaml -n ${PROJECT_CP4AIOPS}
   ```

   (Optional) If you downloaded the status checker script earlier in step 1.1 Download documentation and scripts for offline access, then you can also run this script to see information about the status of your deployment.

If the installation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

5.10 Create an EgressFirewall

There is no egress firewall policy defined when you install IBM Cloud Pak for AIOps, so outgoing traffic from workload pods to the internal and external network is unrestricted.

To create a more secure environment, use the following steps.

1. Create an **EgressFirewall** on your Red Hat OpenShift cluster to limit egress from the IBM Cloud Pak for AIOps project (namespace).

   For more information about creating an **EgressFirewall**, see Configuring an egress firewall for a project.

   Note: There must be only one **EgressFirewall** per project/namespace.

2. Configure exceptions to the **EgressFirewall**.

   Edit your **EgressFirewall** to add exceptions for the following IBM Cloud Pak for AIOps components that have egress dependencies, otherwise these IBM Cloud Pak for AIOps components fail when they attempt egress.

   1. Allow egress to any external services, such as the following integrations:
      - Kubernetes
      - GitHub
      - Microsoft® Teams
      - ServiceNow

- Slack
- VMware® vCenter

2. Configure your **EgressFirewall** to allow traffic for your GitHub, Kubernetes, ServiceNow, and VMware vCenter integrations.

   Edit your **EgressFirewall** to allow or deny egress, as in the following example:

```
kind: EgressFirewall
metadata:
  name: default
spec:
  egress:
  - type: Allow
    to:
      cidrSelector: <1.2.3.0/24>
  - type: Allow
    to:
      dnsName: <www.github.com>
  - type: Allow
    to:
      dnsName: <www.developer.kubernetes.com>
  - type: Allow
    to:
      dnsName: <www.developer.servicenow.com>
  - type: Allow
    to:
      dnsName: <www.developer.vcenter.com>
  - type: Deny
    to:
      cidrSelector: <0.0.0.0/0>
```

   Substitute values for `dnsName` and `cidrSelector` that are the DNS names and addresses of your GitHub, Kubernetes, ServiceNow, or VMware vCenter sources.

5.11 Access the Cloud Pak for AIOps console

After you successfully install IBM Cloud Pak for AIOps, get the URL for accessing the Cloud Pak for AIOps console.

1. Use the following command to get the URL to access the Cloud Pak for AIOps console:

   ```
   oc get route -n ${PROJECT_CP4AIOPS} cpd -o jsonpath='{.spec.host}'
   ```

   The following output is a sample output:

   ```
   cpd-cp4aiops.apps.mycluster.mydomain
   ```

   Based on the sample output, your console URL would be **https://cpd-cp4aiops.apps.mycluster.mydomain**

2. Enter the URL in your browser to open the Cloud Pak for AIOps console. Log in with your username and password.

Find the IBM Cloud Pak for AIOps console username and password

The default username to access the Cloud Pak for AIOps console is **admin**. You can check the default username and their password with the following commands.

Note: This information is for the **IBM provided credentials (admin only)** authentication type.

1. Find the default username.

   ```
   oc -n ${PROJECT_CP4AIOPS} get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_username}' | base64 -d
   && echo
   ```

2. Get the password for the **admin** username.

   ```
   oc -n ${PROJECT_CP4AIOPS} get secret platform-auth-idp-credentials -o jsonpath='{.data.admin_password}' | base64 -d
   ```

   The following extract shows a sample output:

   ```
   EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA
   ```

   Based on the sample output, your password would be **EwK9dj9fwPZHyHTyu9TyIgh9klZSzVsA**.

Important: You can change this default password at any time. For more information, see Changing the cluster administrator password.

What to do next

- Define integrations and applications with Defining.
- You can integrate with IBM Cognos® Analytics. For more information, see Integrating IBM Cognos Analytics with IBM Cloud Pak for AIOps.
- If yo- If you have an existing on-premises IBM Tivoli Netcool/OMNIbus deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/OMNIbus integrations.
- If you have an existing on-premises IBM Tivoli Netcool/Impact deployment, then you can connect it to IBM Cloud Pak for AIOps through an integration. For more information, see Creating IBM Tivoli Netcool/Impact integrations.
- Familiarize yourself with backup and restore procedures. It is recommended that you take regular backups of your IBM Cloud Pak for AIOps deployment. For more information, see Backup and restore.
- For more information about health checks and monitoring, see Health checks and monitoring.

Installing on cloud platforms

When you are installing IBM Cloud Pak® for AIOps on specific cloud platforms, there are some suggested and best practices that you can follow to help you complete the installation process.

While the following suggested and required configurations are only for deployment on Azure Red Hat OpenShift (ARO), Google Cloud Platform (GCP), Red Hat® OpenShift® on IBM Cloud® service (ROKS), Red Hat OpenShift Service on AWS (ROSA), and AWS GovCloud, IBM Cloud Pak for AIOps can be installed on any platform that has a supported version of Red Hat® OpenShift® Container Platform installed that meets all other prerequisities.

View the following topics for guidance on installing IBM Cloud Pak for AIOps on cloud platforms:

- Installing IBM Cloud Pak for AIOps on ARO
- Installing IBM Cloud Pak for AIOps on GCP
- Installing IBM Cloud Pak for AIOps on ROKS
- Installing IBM Cloud Pak for AIOps on ROSA
- Installing IBM Cloud Pak for AIOps on AWS GovCloud

View the following topics for details on the main installation options for installing IBM Cloud Pak for AIOps on Red Hat OpenShift.

- Starter installation (CLI)
- Production installation

Installing IBM Cloud Pak for AIOps on Azure Red Hat OpenShift (ARO)

If you are installing IBM Cloud Pak® for AIOps on Azure Red Hat OpenShift (ARO), then you must complete some additional steps before you rejoin the main installation procedure for installing IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform.

Before you begin

Ensure that you meet the following prerequisites:

- Access to the Azure portal (requires email invitation).
- Red Hat subscription, with username and password.
- Azure account permissions to deploy an ARO cluster. You must have the following permissions directly on the virtual network, on the resource group, or on the subscription containing it:
  - Contributor and User Access Administrator permissions, or
  - Owner permissions

  For example, an Azure user with assigned roles of **`Application administrator`** and **`Conditional Access administrator`** has adequate permission.

Installation procedure

Follow these steps to install IBM Cloud Pak for AIOps on ARO.

1. Configure Azure and Red Hat access
2. Create an ARO cluster
3. Configure storage
4. Install IBM Cloud Pak for AIOps

1. Configure Azure and Red Hat access

1. Install the Azure command-line interface (CLI), **`az`**.

   Follow the instructions Install the Azure CLI on Linux in the Azure documentation.

2. Get an OpenShift pull secret to enable access to the OpenShift container registries.

   1. Log in to the OpenShift cluster manager portal.

   2. Click **Download pull secret** to download the pull secret, and save it to a file called **`pull-secrets.json`**. This file is used in step 2.2

3. Log in to the Azure CLI.

   Run the following command to log in to the Azure CLI, and to find your subscription-id.

   ```
   az login
   az account show | jq .id
   ```

4. Register providers to your Azure account.

   ```
   az account set --subscription <subscription-id>
   az provider register -n Microsoft.RedHatOpenShift --wait
   ```

```
az provider register -n Microsoft.Compute --wait
az provider register -n Microsoft.Storage --wait
az provider register -n Microsoft.Authorization --wait
az feature register --namespace Microsoft.RedHatOpenShift --name preview
```

Where **<subscription-id>** is the subscription-id that you found in the previous step.

2. Create an ARO cluster

1. Create dependant assets.

   Run the following commands to create a virtual network that contains two empty subnets.

   ```
   # Set environment variables for use by the `az` commands
   export SUFFIX=waiops4test
   export LOCATION=eastus
   export RESOURCEGROUP=aro-$SUFFIX
   export CLUSTER=cluster-$SUFFIX

   # Create a resource group
   az group create -g $RESOURCEGROUP -l $LOCATION

   # Create a new virtual network in the resource group that you created above:
   az network vnet create -g $RESOURCEGROUP \
     -n aro-vnet-$SUFFIX \
     --address-prefixes 10.0.0.0/22

   # Add an empty subnet for the master nodes:
   az network vnet subnet create -g $RESOURCEGROUP \
     -n master-subnet-$SUFFIX \
     --vnet-name aro-vnet-$SUFFIX \
     --address-prefixes 10.0.0.0/23 \
     --service-endpoints Microsoft.ContainerRegistry \
     --disable-private-link-service-network-policies true

   # Add an empty subnet for the worker nodes:
   az network vnet subnet create -g $RESOURCEGROUP \
     -n worker-subnet-$SUFFIX \
     --vnet-name aro-vnet-$SUFFIX \
     --address-prefixes 10.0.2.0/23 \
     --service-endpoints Microsoft.ContainerRegistry
   ```

2. Run the following command to create an ARO cluster.

   Note: Use worker-vm-size **Standard_D16s_v3** for a small, starter deployment of IBM Cloud Pak for AIOps and a worker-vm-size of **Standard_D48s_v3** for a large, production deployment of IBM Cloud Pak for AIOps.

   ```
   az aro create -g $RESOURCEGROUP \
     -n $CLUSTER \
     --vnet aro-vnet-$SUFFIX \
     --master-subnet master-subnet-$SUFFIX \
     --worker-subnet worker-subnet-$SUFFIX \
     --worker-count 6 \
     --worker-vm-size Standard_D16s_v3 \
     --master-vm-size Standard_D8s_v3 \
     --pull-secret @pull-secrets.json
   ```

   Note: **pull-secrets.json** must be the file that the Red Hat OpenShift secret was stored in, in step 1.2.

   It takes approximately 35 minutes for the ARO cluster to be created. Progress can be viewed from the Azure console or CLI.

3. When the ARO cluster is created, run the following command to log in to it.

   ```
   oc login \
    -u kubeadmin -p $(az aro list-credentials  -n $CLUSTER -g $RESOURCEGROUP | jq -r .kubeadminPassword) \
    -s $(az aro show  -n $CLUSTER -g $RESOURCEGROUP | jq -r .apiserverProfile.url)
   ```

3. Configure storage

Azure's native storage is not compatible with some IBM Cloud Pak for AIOps components. Configure one of the following supported storage providers for IBM Cloud Pak for AIOps:

- Red Hat® OpenShift® Data Foundation (ODF)
- Portworx Enterprise

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **RWX-storage-class-name** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

3.1 Configuring Red Hat OpenShift Data Foundation

To configure Red Hat OpenShift Data Foundation storage for your IBM Cloud Pak for AIOps on ARO deployment, use the instructions in Deploying OpenShift Data Foundation on Azure Red Hat OpenShift in the Red Hat documentation.

3.2 Configuring Portworx Enterprise

To configure Portworx storage for your IBM Cloud Pak for AIOps on ARO deployment, use the following instructions.

3.2.1 Create secret for Portworx

1. Use a browser to access the Azure portal, **portal.azure.com**, click **Azure Active Directory** and find the value of **Tenant ID** in the returned page.
2. From the command line, run the following command to set an environment that contains the tenant ID.

   ```
   export AZURE_TENANT_ID=<value of the tenant ID>
   ```

3. Use a browser to access the Azure portal, **portal.azure.com**, and then click **Virtual machines**.
4. In the search bar on the **Virtual machines** page, enter the value of your $SUFFIX environment variable as a filter and click the **Name** of any of the returned VMs.
5. Click **Access control (IAM)** on the menu.
6. On the **cluster name | Access control (IAM)** page, click **View** in the **View deny assignments** section.
7. On the **cluster name | Access control (IAM)** page's **Deny assignments** tab, click the link beneath **Name**.
8. On the **Deny assignment | Users** page, click the link in the **Name** column in the **Deny assignment excludes** section.
9. In the **enterprise application | Overview** page, locate the **Application ID** field and copy it.
10. From the command line, run the following command to set an environment variable that contains the application ID.

    ```
    export AZURE_CLIENT_ID=<value of the application ID>
    ```

11. Use a browser to navigate to the Azure portal, **portal.azure.com**, and then click **Azure Active Directory**.
12. On the **Azure Active Directory | Overview** page, click **App registrations** on the menu.
13. On the **Azure Active Directory | App registrations** page, enter the cluster's client-id (that you just exported) in the filter field, and then click the link in the **Display name** column.
14. On the returned **Application registration details** page, click **Certificates and secrets** on the menu.
15. In the **Certficates and secrets** page, select **+ New client secret** to create a new client secret.
16. In the **Add a client secret** page, enter a **Description** and an **Expiry**, and select **Add**.
17. On the **Certificates and secrets** page, locate the secret that you just added in the **Client secrets** section. Then select the copy icon next to the **Value** column to get the secret.
18. From the command line, run the following command to set an environment variable that contains the client secret.

    ```
    export AZURE_CLIENT_SECRET=<value of the client secret>
    ```

19. Create a secret

    Run the following command to create the secret

    ```
    oc delete secret px-azure -n kube-system
    oc create secret generic px-azure \
    -n kube-system \
    --from-literal=AZURE_TENANT_ID=${AZURE_TENANT_ID} \
    --from-literal=AZURE_CLIENT_ID=${AZURE_CLIENT_ID} \
    --from-literal=AZURE_CLIENT_SECRET=${AZURE_CLIENT_SECRET}
    ```

3.2.2 Create a Portworx spec

A Portworx Enterprise spec is required to set up a Portworx storage cluster.

1. From a browser, go to https://portworx.com, select **LOGIN**, and log in to your Portworx account. Select to use the Portworx Enterprise edition. Then, click **Continue**, and **Continue** again on the Portworx product comparison page.
2. On the **Spec Generator - Enterprise** page, enter or select the following settings and then click **Next**.
   1. Select the checkbox for **Use the Portworx Operator**.
   2. Select *2.10* for the **Portworx Version**.
   3. Select the *Built-in* radio button for **ETCD**.
3. On the next page, set the following values and then click **Next**.
   1. For **Select your environment**, select the *Cloud* radio button.
   2. Under **Select Cloud Platform**, select *AZURE*.
   3. Under **Configure storage devices**, select *Create Using a Spec*
   4. Under **Size(GB)**, select *2000 GB*
4. Click **Next** to skip the Network configuration page.
5. On the **Customize** page, select **Azure Kubernetes Service (AKS)**, then click **Finish**, and click **Agree** to accept the license agreement.
6. In the **spec** page, highlight and select the live download URL.

   For example, **https://install.portworx.com/2.10?operator=true&mc=false&kbver=&b=true&kd=type%3DPremium_LRS%2Csize%3D150&s=%22type%3DPremium_LRS%2Csize%3D2000%22&c=p**

```
x-cluster-e0fb19ba-4e45-4175-b92e-18003948b965&aks=true&stork=true&csi=true&mon=true&tel=false&st=k8s&promop=true
```

3.2.3 Installing the Portworx operator from Red Hat OpenShift Container Platform

1. Open the Red Hat OpenShift Container Platform console for your Red Hat OpenShift Service on AWS cluster.

   If you need to find your ARO cluster credentials and console URL, you can use the following commands.

   ```
   az aro list-credentials  -n $CLUSTER -g $RESOURCEGROUP
   az aro show  -n $CLUSTER -g $RESOURCEGROUP | jq -r .consoleProfile.url
   ```

2. Go to **Operators** > **OperatorHub**.
3. Search for *Portworx Enterprise*. Then, click **Install** > **Install**.

   Warning: Do not click *Create StorageCluster*. You will create the storage cluster in the next step, with the spec that you saved.

4. *Portworx Enterprise* is now listed under **Operators** > **Installed Operators**.

3.2.4 Create the Portworx storage cluster

1. From the command line, run the following command to load the Portworx spec that you created into the ARO cluster.

   ```
   export PORTWORX_SPEC_URL=<spec_URL>
   curl -ks "${PORTWORX_SPEC_URL}&osft=true" | oc apply -f -
   ```

   Where **<spec_URL>** is the spec URL that you copied earlier.

2. From the console, go to **Operators** > **Installed Operators** > **Portworx Enterprise** and select the **StorageClusters** tab. The storage cluster is ready when the **Status** changes from *Phase: Initializing* to *Phase: Online*.
3. Create the Portworx storage classes. Follow the **Define a custom Portworx storage class** instructions in Installing recommended storage providers and configuring storage classes: Portworx.

4. Install IBM Cloud Pak for AIOps

You are now ready to install IBM Cloud Pak for AIOps.

Follow the procedure for installing IBM Cloud Pak for AIOps from step 3 in one of the following topics, according to your requirements:

- Starter installation (CLI)
- Online production installation of IBM Cloud Pak for AIOps (console method)
- Online production installation of IBM Cloud Pak for AIOps (CLI method)

Deleting the ARO cluster

If you no longer require your ARO cluster, you can remove it with the following command.

```
az aro delete -y -g $RESOURCEGROUP -n $CLUSTER
```

Installing IBM Cloud Pak for AIOps on Google Cloud Platform

Follow this procedure if you want to install IBM Cloud Pak® for AIOps on a Red Hat® OpenShift® Container Platform cluster on Google Cloud Platform (GCP).

Installation procedure

1. Create a Red Hat OpenShift cluster on GCP
2. Configure storage
3. Install IBM Cloud Pak for AIOps

1. Create a Red Hat OpenShift cluster on GCP

Install a Red Hat OpenShift cluster on GCP. For more information, see the Red Hat documentation Installing on Google Cloud Platform.

2. Configure storage

Configure one of the following storage providers for IBM Cloud Pak for AIOps:

- Red Hat® OpenShift® Data Foundation (ODF)
- Portworx Enterprise

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **RWX-storage-class-name** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

2.1 Configuring ODF

To configure ODF storage for your IBM Cloud Pak for AIOps deployment, use the instructions in the Red Hat documentation Deploying and managing OpenShift Data Foundation using Google Cloud.

Important: Read the statement about the technology preview status of Red Hat® OpenShift® Data Foundation on GCP in the previous link.

2.2 Configuring Portworx Enterprise

To configure Portworx storage for your IBM Cloud Pak for AIOps on GCP deployment, use the following instructions.

2.2.1 Create a Portworx spec

A Portworx Enterprise spec is required to set up a Portworx storage cluster. For more information, see GCP in the Portworx documentation.

1. From a browser, go to https://portworx.com, select **LOGIN**, and log in to your Portworx account. Select to use the Portworx Enterprise edition. Then, click **Continue**, and **Continue** again on the Portworx product comparison page.
2. On the **Spec Generator - Enterprise** page, enter or select the following settings and then click **Next**.
    1. Select the checkbox for **Use the Portworx Operator**.
    2. Select *2.10* for the **Portworx Version**.
    3. Select the *Built-in* radio button for **ETCD**.
3. On the next page, set the following values and then click **Next**.
    1. For **Select your environment**, select the *Cloud* radio button.
    2. Under **Select Cloud Platform**, select *Google cloud/GKE*.
    3. Under **Configure storage devices**, select *Create Using a Spec*
    4. Under **Size(GB)**, select *2000 GB*
4. Click **Next** to skip the Network configuration page.
5. On the **Customize** page, select **Google Kubernetes Engine (GKE)**, then click **Finish**, and click **Agree** to accept the license agreement.
6. In the **spec** page, highlight and select the live download URL.

    For example,

    ```
    https://install.portworx.com/2.10?
    operator=true&mc=false&kbver=&b=true&kd=type%3DPremium_LRS%2Csize%3D150&s=%22type%3DPremium_LRS%2Csize%3D2000%22&c=px-cluster-e0fb19ba-4e45-4175-b92e-18003948b965&aks=true&stork=true&csi=true&mon=true&tel=false&st=k8s&promop=true
    ```

2.2.2 Configure GCP for Portworx

1. Open the worker node ports 17001-17020 to the master node network. For more information, see Firewall policy rules in the GCP documentation.
2. The worker node's service account (created by the Red Hat OpenShift installer) must have the following roles:

    ```
    Compute Admin
    Service Account User
    Kubernetes Engine Cluster Viewer
    ```

    You can view and edit the roles by opening the GCP console, and selecting **IAM & Admin** > **Service Accounts**. For more information, see in the GCP documentation.

2.2.3 Installing the Portworx operator from Red Hat OpenShift Container Platform

1. Open the Red Hat OpenShift Container Platform console for your GCP cluster.
2. Go to **Operators** > **OperatorHub**.
3. Search for *Portworx Enterprise*. Then, click **Install** > **Install**.

    Warning: Do not click *Create StorageCluster*. You will create the storage cluster in the next step, with the spec that you saved.
4. Portworx Enterprise should now be listed under **Operators** > **Installed Operators**.

2.2.4 Create the Portworx storage cluster

1. From the command line, run the following command to load the Portworx spec that you created into the GCP cluster.

    ```
    export PORTWORX_SPEC_URL=<spec_URL>
    curl -ks "${PORTWORX_SPEC_URL}" | oc apply -f -
    ```

    Where **<spec_URL>** is the spec URL that you copied earlier.
2. From the console, go to **Operators** > **Installed Operators** > **Portworx Enterprise** and select the **StorageClusters** tab. The storage cluster is ready when the **Status** changes from *Phase: Initializing* to *Phase: Online*.
3. Create the Portworx storage classes. Follow the **`Define a custom Portworx storage class`** instructions in Installing recommended storage providers and configuring storage classes: Portworx.

3. Install IBM Cloud Pak for AIOps

You are now ready to install IBM Cloud Pak for AIOps.

Follow the procedure for installing IBM Cloud Pak for AIOps from step 3 in one of the following topics, according to your requirements:

- Starter installation (CLI)
- Online production installation of IBM Cloud Pak for AIOps (console method)
- Online production installation of IBM Cloud Pak for AIOps (CLI method)

Installing IBM Cloud Pak for AIOps on Red Hat OpenShift on IBM Cloud (ROKS)

If you are installing on Red Hat OpenShift on IBM Cloud (ROKS), you can follow any of the main online installation options for installing IBM Cloud Pak® for AIOps. For installing on Red Hat OpenShift on IBM Cloud, you need to replace any storage class configuration with your configured storage class for Red Hat OpenShift on IBM Cloud.

- Starter installation (CLI)
- Production installation(online installation only)

Storage

Installing on a classic infrastructure:

When you are configuring storage as part of the installation, consider using the default storage that is available with Red Hat OpenShift on IBM Cloud (ROKS). This storage has been tested with a IBM Cloud Pak for AIOps deployment on Red Hat OpenShift on IBM Cloud. You can choose to deploy and use your own storage if needed or preferred.

The following storage classes are the default storage classes for Red Hat OpenShift on IBM Cloud:

- `storageClass: ibmc-file-gold-gid`
- `storageClassLargeBlock: ibmc-block-gold`

Note: `ibmc-file-gold-gid` does not have volume expansion enabled by default, which is required by IBM Cloud Pak for AIOps. For more information, see Storage class requirements.

Installing on VPC infrastructure (using Red Hat OpenShift Data Foundation storage):

Consider using Red Hat OpenShift Data Foundation storage. This storage has been tested with a IBM Cloud Pak for AIOps deployment on Red Hat OpenShift on IBM Cloud. To use this storage provider, you need to first deploy Red Hat OpenShift Data Foundation on your CPV cluster. For more information, see Deploying OpenShift Data Foundation on VPC clusters.

When you do use this storage, the following storage classes are the default storage classes to use for Red Hat OpenShift on IBM Cloud:

- `storageClass: ocs-storagecluster-cephfs`
- `storageClassLargeBlock: ocs-storagecluster-ceph-rbd`

For more information about these storage classes, see the IBM Cloud Docs Storage class reference.

Installing IBM Cloud Pak for AIOps on Red Hat OpenShift Service on AWS (ROSA)

If you are installing IBM Cloud Pak® for AIOps on Red Hat OpenShift Service on AWS (ROSA), then you must complete some additional steps before you rejoin the main installation procedure for installing IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform.

Before you begin

Ensure that you meet the following prerequisites:

- You have an AWS account.
- You have a Red Hat subscription.
- Ensure that your environment meets the prerequisites for Red Hat OpenShift Service on AWS.

Installation procedure

Follow these steps to install IBM Cloud Pak for AIOps on Red Hat OpenShift Service on AWS

1. Configure AWS and Red Hat access
2. Create a Red Hat OpenShift Service on AWS Red Hat OpenShift Container Platform cluster
3. Configure storage
4. Install IBM Cloud Pak for AIOps

1. Configure AWS and Red Hat access

1. Log in to the AWS console to verify that you have access to the console. If needed, the *Login* page provides a link to register for an account.

2. From the AWS console, deploy Red Hat OpenShift Container Platform into a VPC within your AWS environment if it is not already deployed. For more information see Red Hat OpenShift Service on AWS quickstart guide.
3. Log in to the Red Hat console to verify that you have access to the console. If needed, the *Login* page provides a link to register for an account.
4. Retrieve your Red Hat Red Hat OpenShift Cluster Manager API Token by entering the following URL:
   - https://console.redhat.com/openshift/token/rosa/show
5. Configure the ROSA CLI to work with your AWS account. For more information, see Install and configure the latest ROSA CLI.
6. (Optional) Create a test cluster to validate your environment configuration
   1. Log in to Red Hat OpenShift Service on AWS.

      ```
      rosa login --token="<token>"
      ```

   2. Configure your AWS account to allow a IAM (non-STS) ROSA cluster.

      ```
      rosa init
      ```

   3. Create the test cluster.

      ```
      rosa create cluster --cluster-name=mytest
      ```

      During the cluster creation, you can review the installation logs to watch the progress.

      ```
      rosa logs install -c mytest --watch
      ```

   4. After the installation completes, list the cluster and note the cluster ID.

      ```
      rosa list clusters
      ```

   5. Describe your cluster using the cluster ID.

      ```
      rosa describe cluster -c 1ab23de4fghijk5lmno6p78q9r1stu2v
      ```

   6. Add an identity provider.

      ```
      rosa create idp --cluster 1ab23de4fghijk5lmno6p78q9r1stu2v --interactive
      ```

      You need to use the noninteractive mode and get some constant values to use

   7. Create your initial admin account.

      ```
      rosa create admin --cluster=1ab23de4fghijk5lmno6p78q9r1stu2v
      ```

   8. Log in to your test cluster by using the admin and password.

      ```
      oc login https://api.jgtest01.dj5a.p1.openshiftapps.com:6443 --username cluster-admin --password XXXXXX
      ```

      If your login is successful, your test cluster is working and your environment is configured.

   9. Clean up and delete the test cluster to proceed with creating your main cluster.

      ```
      rosa delete cluster -c 1ab23de4fghijk5lmno6p78q9r1stu2v
      ```

2. Create a Red Hat OpenShift Service on AWS Red Hat OpenShift Container Platform cluster

1. Log in to the Red Hat OpenShift Service on AWS CLI.

   ```
   rosa login
   ```

   Log in to the site https://cloud.redhat.com/openshift/token/rosa to retrieve your token. Then, copy and paste the token into the CLI prompt.

2. Create your cluster.

   ```
   rosa create cluster --cluster-name=<myclustername> --compute-machine-type=m5.8xlarge  --compute-nodes=<Number of Compute Nodes>  --version <Red Hat OpenShift_version>
   ```

   Example:

   ```
   rosa create cluster --cluster-name=cluster-test1  --compute-machine-type=m5.8xlarge  --compute-nodes=6 --version 4.16
   ```

3. After your cluster is ready, create your cluster administrator account.
   1. Run the following command:

      ```
      rosa create admin -c <myclustername>
      ```

      Important: Record the admin username (cluster-admin) and password for future use.

   2. Run the `oc login` command with the cluster administrator credentials.
4. Verify that all nodes are in `Ready` state before proceeding. Your cluster may take 40+ minutes to create and for you to be able to successfully log in with the 'oc login' command.

1. Run the following command:

   ```
   oc get nodes
   ```

2. Run the following command:

   ```
   rosa describe cluster -c <myclustername>
   ```

   Record the console URL for the Red Hat OpenShift Console and the Details Page for viewing the cluster details.

3. Verify that you can access the Red Hat OpenShift console by logging in to the provided Red Hat OpenShift console URL using the **cluster-admin** role and credentials.

3. Configure storage

AWS native storage and Portworx are tested and supported storage options for installing IBM Cloud Pak for AIOps on ROSA. Use the following instructions to configure AWS native storage or Portworx as your storage solution.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **RWX-storage-class-name** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

AWS native storage

The AWS native storage class that is required by IBM Cloud Pak for AIOps is **gp3-csi**. If you want to use OADP backup and restore, the **efs-sc** AWS native storage class is required. Storage class configuration cannot be changed after installing IBM Cloud Pak for AIOps.

Amazon Elastic Block Store (EBS) provides block storage. The storage class is **gp3-csi**, and is created when ROSA is installed.

Amazon Elastic File System (EFS) provides file storage. The storage class is **efs-sc**, and you must create it. For more information, see **Setting up the AWS EFS CSI Driver Operator** and **Creating the AWS EFS storage class** in the Red Hat OpenShift documentation. You can also review the information in the Red Hat article Enabling the AWS EFS CSI Driver Operator on ROSA.

Portworx

To use Portworx for storage you must have a Portworx account and license. If needed, register for a Portworx account.

3.1 Configure the Portworx services spec

1. Log in to your Portworx account. Select to use the Portworx Enterprise edition. Then, click **Next**.
2. On the *Spec Generator - Enterprise* page, enter or select the following settings for your storage:
   1. Select the checkbox for *Use the Portworx Operator*.
   2. Select **2.10** or higher for the Portworx Version.
   3. Select the *Built-in* radio button for ETCD. Click **Next**.
   4. Select the *Cloud* radio button. Then, select *AWS* for Cloud Platform.
   5. Select the type of disk: *Create Using a Spec*
   6. Select the EBS volume type: **GP2**, Size (GB): **2000**. Click **Next**.
   7. Click **Next** to skip the Network configuration page.
   8. On the *Customize* page, select *OpenShift 4+*. Click **Finish**.
   9. Click *Agree* to accept the license agreement.
   10. Choose your own values to enter under the *Spec Name* and *Spec Tags* fields. Then, click **Save Spec**.
3. From *Spec List* page, find your Spec name and expand the Actions column menu and select **Copy to Clipboard**. Save the kubectl command. You use this command later.

3.2 Configure the AWS infrastructure for Portworx storage

1. Edit the Inbound Rules for both your master and worker nodes to allow for Network File System (NFS).
   1. Log in to the AWS EC2 Console.
   2. Under *EC2*, select *Instances*. Click an Instance ID for one of your worker nodes.
   3. Click the **Security** tab, and click the Security Group Name for the node.
   4. Click **Edit Inbound Rules**. Scroll to the bottom, and click **Add Rule**.
   5. Update the following settings for the rule:
      - Expand the first drop-down menu, and change the setting from *Custom TCP* to *All TCP*.
      - In the *CIDR blocks Source* field, enter **10.0.0.0/8**.
      - For the ports, open the following ports: 111, 2049, 20048, 17001-17020, 27017.
      - If you encounter issues during the installation, considering opening all inbound ports from **10.0.0.0/8**.
   6. Click **Save rules**.
   7. Repeat the above steps for your other nodes.
2. Create your Portworx policy in the AWS Identity and Access Management (IAM) tool.
   1. Go to **IAM** > **Access management** > **Policies**.
   2. Choose **Create policy**.
   3. Choose the **JSON** tab.
   4. Replace all the text with the following content:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PortworxPolicy",
      "Effect": "Allow",
      "Action": [
        "ec2:AttachVolume",
        "ec2:ModifyVolume",
        "ec2:DetachVolume",
        "ec2:CreateTags",
        "ec2:CreateVolume",
        "ec2:DeleteTags",
        "ec2:DeleteVolume",
        "ec2:DescribeTags",
        "ec2:DescribeVolumeAttribute",
        "ec2:DescribeVolumesModifications",
        "ec2:DescribeVolumeStatus",
        "ec2:DescribeVolumes",
        "ec2:DescribeInstances",
        "autoscaling:DescribeAutoScalingGroups"
      ],
    "Resource": [
      "*"
    ]
  }
]
}
```

5. Click **Next: Tags**. Then, click **Next: Review**.
6. Enter the name for your new policy. Then, click **Create policy**.

3. Attach the policy.
    1. Go to **IAM** > **Roles**.
    2. Click the worker-role name for your cluster.
    3. Click **Attach policy**. Search for, and select, the policy that you created. Then, select to attach the policy.

3.3 Install the Portworx operator from Red Hat OpenShift Container Platform

1. Open the Red Hat OpenShift Container Platform console for your Red Hat OpenShift Service on AWS cluster.
2. Go to **Operators** > **OperatorHub**.
3. Search for Portworx Enterprise. Then, click **Install** > **Install**.
4. Portworx Enterprise is now be listed under *Installed Operators*.

3.4 Configure the Portworx operator

1. Import the Spec from Portworx.
    1. Run `oc login` to log in to your Red Hat OpenShift Service on AWS cluster.
    2. Run `kubectl apply -f <command>` where `<command>` is the command that you saved earlier from the Portworx console.
2. Verify that Portworx Enterprise shows as one of the Installed Operators in `Project: kube-system`. Click Portworx Enterprise tile.

   In the **Storage Cluster** tab, you can see the storage cluster being initialized. Wait until Status is `Phase: Online`.

3. Create the Portworx storage classes. Follow the `Define a custom Portworx storage class` instructions in Installing recommended storage providers and configuring storage classes: Portworx.

4. Install IBM Cloud Pak for AIOps

You are now ready to install IBM Cloud Pak for AIOps.

Follow the procedure for installing IBM Cloud Pak for AIOps from step 3 in one of the following topics, according to your requirements:

- Starter installation (CLI)
- Online production installation of IBM Cloud Pak for AIOps (console method)
- Online production installation of IBM Cloud Pak for AIOps (CLI method)

Deleting the Red Hat OpenShift Service on AWS cluster

If you no longer require your Red Hat OpenShift Service on AWS cluster, you can remove it with the following steps.

1. Run `oc login` to log in to your Red Hat OpenShift Service on AWS cluster.
2. Run the following command to delete the cluster:

   ```
   rosa delete cluster -c <clustername> --watch
   ```

3. Run the following command to verify that the cluster is deleted:

   ```
   rosa list clusters
   ```

   Ensure that your cluster no longer is listed.

4. Delete any Identity and Access Management (IAM) policies for the cluster.

Installing IBM Cloud Pak for AIOps on AWS GovCloud

If you are installing IBM Cloud Pak® for AIOps on AWS GovCloud, then you must complete some additional steps before you rejoin the main installation procedure for installing IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform.

Getting Started with IBM Cloud Pak for AIOps and AWS Marketplace

When you purchase IBM Cloud Pak for AIOps through the Amazon Web Services (AWS) Marketplace, IBM begins processing your order immediately. To complete your deployment, use the following steps:

- Obtain your IBM Cloud Pak for AIOps entitlement key by following the prompts that are provided in the **`Order Processed Successfully`** email that you received from IBM. The entitlement key is needed to install IBM Cloud Pak for AIOps.
- Obtain your Red Hat® OpenShift® Container Platform entitlement by following the prompts that are provided in the **`ACTION NEEDED: Your Red Hat Account Update`** email that you received from IBM, or in the **`Your Red Hat order has been processed`** email that you received from Red Hat. The sender and content of this email depends on the product purchased.
- Review the information about enabling FIPS compliance for IBM Cloud Pak for AIOps: Federal Information Processing Standards (FIPS).
- Review the storage requirements for IBM Cloud Pak for AIOps: Hardware requirements - Storage.
- Review the information about viewing your audit logs: Audit logging. Audit logging is a FISMA requirement. When you complete your deployment, audit logging is configured and enabled by default.

Before you begin

Ensure that you meet the following prerequisites:

- You have an AWS GovCloud account.
- You have a Red Hat subscription.
- You have a Portworx account and license. The following steps are tested with, and require, Portworx storage. If needed, register for a Portworx account.
- Ensure that your environment meets the prerequisites for AWS GovCloud.

Installation procedure

Follow these steps to install IBM Cloud Pak for AIOps on AWS GovCloud:

1. Create a Red Hat OpenShift Container Platform cluster on AWS GovCloud
2. Configure storage
3. Install IBM Cloud Pak for AIOps

1. Create a Red Hat OpenShift cluster on AWS GovCloud

To create your Red Hat OpenShift cluster, follow the instructions in the Red Hat OpenShift documentation for Installing a Cluster on AWS into a Government Region.

These steps include provisioning a Virtual Private Cloud (VPC) in your AWS account that conforms to the requirements for Red Hat OpenShift Container Platform.

Important:

- When you are defining the **`install-config.yaml`** for your Red Hat OpenShift deployment, select worker and master nodes that meet your resource requirements for IBM Cloud Pak for AIOps as detailed in the topic Hardware requirements - Storage.
- If your deployment must be FIPS compliant, then you must comply with the steps in Enabling Federal Information Processing Standards (FIPS) support for IBM Cloud Pak for AIOps when creating your Red Hat OpenShift cluster and configuring your IBM Cloud Pak for AIOps installation.

2. Configure storage

Portworx is the tested and supported storage option for installing IBM Cloud Pak for AIOps on AWS GovCloud.

Note: Storage classes and storage providers cannot be changed after you install IBM Cloud Pak for AIOps. OADP backup and restore requires that a ReadWriteMany (RWX) storage class must be provided. If OADP backup and restore is not needed, a ReadWriteOnce (RWO) storage class can be provided as the **`RWX-storage-class-name`** in the installation instance CR YAML file. This configuration cannot be changed after IBM Cloud Pak for AIOps is installed.

2.1 Configure the Portworx services spec

1. Log in to your Portworx account. Select to use the Portworx Enterprise edition. Then, click **Next**.
2. On the *Spec Generator - Enterprise* page, enter or select the following settings for your storage:
    1. Select the checkbox for *Use the Portworx Operator*.
    2. Select **`2.10`** or higher for the Portworx Version.
    3. Select the *Built-in* radio button for ETCD. Click **Next**.
    4. Select the *Cloud* radio button. Then, select *AWS* for Cloud Platform.

5. Select the type of disk: *Create Using a Spec*
6. Select the EBS volume type: `GP2`, Size (GB): `2000`. Click **Next**.
7. Click **Next** to skip the *Network configuration* page.
8. On the *Customize* page, select *OpenShift 4+*. Click **Finish**.
9. Click *Agree* to accept the license agreement.
10. Choose your own values to enter under the *Spec Name* and *Spec Tags* fields. Then, click **Save Spec**.

3. From the *Spec List* page, find your Spec name and expand the Actions column menu and select **Copy to Clipboard**. Save the kubectl command, which is needed later.

2.2 Configure the AWS infrastructure for Portworx storage

1. Edit the Inbound Rules for both your master and worker nodes to allow for Network File System (NFS).

    1. Log in to the AWS EC2 Console.
    2. Under *EC2*, select *Instances*. Click an Instance ID for one of your worker nodes.
    3. Click the **Security** tab, and click the Security Group Name for the node.
    4. Click **Edit Inbound Rules**. Scroll to the bottom, and click **Add Rule**.
    5. Update the following settings for the rule:
        - Expand the first drop-down menu, and change the setting from *Custom TCP* to *All TCP*.
        - In the *CIDR blocks Source* field, enter `10.0.0.0/8`.
        - For the ports, open the following ports: 111, 2049, 20048, 17001-17020, 27017.
        - If you encounter issues during the installation, considering opening all inbound ports from `10.0.0.0/8`.
    6. Click **Save rules**.
    7. Repeat the preceding steps for your other nodes.

2. Create your Portworx policy in the AWS Identity and Access Management (IAM) tool.

    1. Go to **IAM** > **Access management** > **Policies**.
    2. Choose **Create policy**.
    3. Choose the **JSON** tab.
    4. Replace all the text with the following content:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "PortworxPolicy",
      "Effect": "Allow",
      "Action": [
        "ec2:AttachVolume",
        "ec2:ModifyVolume",
        "ec2:DetachVolume",
        "ec2:CreateTags",
        "ec2:CreateVolume",
        "ec2:DeleteTags",
        "ec2:DeleteVolume",
        "ec2:DescribeTags",
        "ec2:DescribeVolumeAttribute",
        "ec2:DescribeVolumesModifications",
        "ec2:DescribeVolumeStatus",
        "ec2:DescribeVolumes",
        "ec2:DescribeInstances",
        "autoscaling:DescribeAutoScalingGroups"
      ],
    "Resource": [
      "*"
    ]
  }
]
}
```

    5. Click **Next: Tags**. Then, click **Next: Review**.
    6. Enter the name for your new policy. Then, click **Create policy**.

3. Attach the policy.

    1. Go to **IAM** > **Roles**.
    2. Click the worker-role name for your cluster.
    3. Click **Attach policy**. Search for, and select, the policy that you created. Then, select to attach the policy.

2.3 Install the Portworx operator from Red Hat OpenShift Container Platform

1. Open the Red Hat OpenShift Container Platform console for your AWS GovCloud cluster.
2. Go to **Operators** > **OperatorHub**.
3. Search for Portworx Enterprise. Then, click **Install** > **Install**.
4. Portworx Enterprise is now be listed under *Installed Operators*.

2.4. Configure the Portworx operator

1. Import the Spec from Portworx.

    1. Run `oc login` to log in to your AWS GovCloud cluster.

2. Run `kubectl apply -f <command>` where `<command>` is the command that you saved earlier from the Portworx console.

2. Verify that Portworx Enterprise shows as one of the Installed Operators in `Project: kube-system`. Click Portworx Enterprise tile.

   In the **Storage Cluster** tab, you can see the storage cluster initialization. Wait until the Status is `Phase: Online`.

3. Create the Portworx storage classes. Follow the `Define a custom Portworx storage class` instructions in Installing recommended storage providers and configuring storage classes: Portworx.

3. Install IBM Cloud Pak for AIOps

You are now ready to install IBM Cloud Pak for AIOps.

Follow the procedure for installing IBM Cloud Pak for AIOps from step 3 in one of the following topics, according to your requirements:

- Starter installation (CLI)
- Online production installation of IBM Cloud Pak for AIOps (console method)
- Online production installation of IBM Cloud Pak for AIOps (CLI method)

Upgrading IBM Cloud Pak for AIOps on OpenShift

Upgrade an existing online or offline deployment of IBM Cloud Pak® for AIOps 4.7.0 or later to 4.8.0.

You cannot use these instructions to upgrade deployments of IBM Cloud Pak for AIOps 4.6.1 or earlier.

Important: If IBM® Netcool® Operations Insight® is deployed on the same cluster as IBM Cloud Pak for AIOps, ensure that Netcool Operations Insight is at version 1.6.13 or later before you upgrade IBM Cloud Pak for AIOps. Failure to do so may result in a broken Netcool Operations Insight deployment, as the IBM Cloud Pak for AIOps upgrade process updates a shared component that is used by both applications.

Upgrade paths

IBM Cloud Pak for AIOps uses a versioning system of X.Y.Z, where X=version, Y=release, and Z=patch. For example, IBM Cloud Pak for AIOps 4.7.1 is version 4, release 7, patch 1. IBM Cloud Pak for AIOps upgrades can be release upgrades or patch upgrades.

You can upgrade by a maximum of one release at a time. If the release that you want to upgrade from is more than one release behind the release that you are upgrading to, then you must upgrade sequentially. For example, you cannot upgrade directly from IBM Cloud Pak for AIOps 4.4.0 to v4.8.0, you must use the following sequence:

1. Use the v4.5.1 documentation to upgrade from IBM Cloud Pak for AIOps 4.4.0 to v4.5.1.
2. Use the v4.6.1 documentation to upgrade from IBM Cloud Pak for AIOps 4.5.1 to v4.6.1.
3. Use the v4.7.1 documentation to upgrade from IBM Cloud Pak for AIOps 4.6.1 to v4.7.1.
4. Use this documentation, the v4.8.0 documentation to upgrade from IBM Cloud Pak for AIOps 4.7.1 to v4.8.0.

Controlling upgrade

From IBM Cloud Pak for AIOps 4.7.0 onwards, all upgrades must be initiated manually. Automatic upgrade of IBM Cloud Pak for AIOps does not occur. For more information, see Whats New in the IBM Cloud Pak for AIOps 4.7.0 documentation.

Guidance for upgrades that require an Red Hat OpenShift upgrade

Before you upgrade IBM Cloud Pak for AIOps, ensure that you are on a version of Red Hat® OpenShift® Container Platform that your current and target versions of IBM Cloud Pak for AIOps both support. This helps to ensure compatibility and avoid potential issues caused by platform API changes.

If you already have a version of Red Hat OpenShift that your current and target versions of IBM Cloud Pak for AIOps both support but you want to upgrade Red Hat OpenShift, then complete the IBM Cloud Pak for AIOps upgrade before you upgrade Red Hat OpenShift.

Example upgrade scenario

You have IBM Cloud Pak for AIOps 4.7.0 deployed on Red Hat OpenShift 4.13, and you want to upgrade to IBM Cloud Pak for AIOps 4.8.0 on Red Hat OpenShift 4.17.

The following table shows the supported Red Hat OpenShift versions for your current and target versions of IBM Cloud Pak for AIOps:

Table 1. Supported Red Hat OpenShift versions for current and target application versions

IBM Cloud Pak for AIOps version	Supported Red Hat OpenShift versions
4.7.0	4.10, 4.11, 4.12, 4.13, 4.14, 4.15, 4.16
4.8.0	4.14, 4.15, 4.16, 4.17

The upgrade steps for this example upgrade scenario are:

1. Upgrade Red Hat OpenShift 4.13 to v4.14, v4.15, or v4.16.
2. Upgrade IBM Cloud Pak for AIOps 4.7.0 to v4.8.0.
3. Upgrade Red Hat OpenShift to v4.17.

Upgrade procedure

The upgrade procedure depends on whether your deployment is an online or offline (air-gapped) deployment:

- Online upgrade of IBM Cloud Pak for AIOps (console method)
- Online upgrade of IBM Cloud Pak for AIOps (CLI method)
- Offline upgrade of IBM Cloud Pak for AIOps

For more information about online and offline deployments, see Installing IBM Cloud Pak for AIOps.

Online upgrade of IBM Cloud Pak for AIOps (console method)

Use these instructions to upgrade an online deployment of IBM Cloud Pak® for AIOps 4.7.0 or later to 4.8.0.

Overview

This procedure is for deployments of IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform. This procedure can be used on an online deployment of IBM Cloud Pak for AIOps 4.7.0 or later, and can still be used if the deployment has had hotfixes applied.

You cannot use these instructions to upgrade deployments of IBM Cloud Pak for AIOps 4.6.1 or earlier. For more information, see Upgrade paths.

If you have an offline deployment of IBM Cloud Pak for AIOps on Red Hat OpenShift, follow the instructions in Upgrading IBM Cloud Pak for AIOps (offline).

If you have a deployment of IBM Cloud Pak for AIOps on Linux, follow the instructions in Online upgrade of IBM Cloud Pak for AIOps on Linux.

Important: If IBM® Netcool® Operations Insight® is deployed on the same cluster as IBM Cloud Pak for AIOps, ensure that Netcool Operations Insight is at version 1.6.13 or later before you upgrade IBM Cloud Pak for AIOps. Failure to do so may result in a broken Netcool Operations Insight deployment, as the IBM Cloud Pak for AIOps upgrade process updates a shared component that is used by both applications.

Before you begin

Notes:

- Ensure that you are on a version of Red Hat OpenShift that your current and target versions of IBM Cloud Pak for AIOps both support. If you already have a qualifying version of Red Hat OpenShift but you want to upgrade it, then complete the IBM Cloud Pak for AIOps upgrade first. For more information, see Guidance for upgrades that require an Red Hat OpenShift upgrade.
- Some steps must still be performed with the Red Hat® OpenShift® Container Platform command line interface (CLI). Ensure that you are logged in to your Red Hat OpenShift Container Platform cluster with `oc login` for any steps that use the OpenShift command-line interface (CLI).
- Red Hat OpenShift Container Platform requires a user with `cluster-admin` privileges for the following operations:
  - Update the catalog
  - Update the operator subscription

Warnings:

- Custom patches, labels, and manual adjustments to IBM Cloud Pak for AIOps resources are lost when IBM Cloud Pak for AIOps is upgraded, and must be manually reapplied after upgrade. For more information, see Manual adjustments are not persisted.
- The upgrade cannot be removed or rolled back.
- If you previously increased the size of a PVC directly, then you must follow the correct procedure that is supplied in Resizing storage to ensure that the size is updated by the operator. Failure to do so before upgrading IBM Cloud Pak for AIOps causes the operator to attempt to restore a lower default value for the PVC, and causes an error in your IBM Cloud Pak for AIOps deployment.

Database migration during upgrade

The IBM Cloud Pak for AIOps 4.7.x to v4.8 upgrade process migrates the Elasticsearch database to an OpenSearch database.

Extra resources are needed during the upgrade, and are shown in the following table. These resources can be released after the upgrade is complete.

Table 1. Extra resources required during upgrade

Size	vCPU	Memory	Disk
Starter	2	8Gi	100Gi
Production	6	24Gi	300Gi

If IBM Sales representatives and Business Partners supplied you with a custom profile, then you must calculate the additional resource requirements as follows:

1. Run the following commands to view your custom profile ConfigMap.

   ```
   export PROJECT_CP4AIOPS=<project>
   oc get configmap -n "${PROJECT_CP4AIOPS}" $(oc get installation -n "${PROJECT_CP4AIOPS}" -o
   jsonpath='{.items[0].status.customProfileConfigmap}') -o yaml
   ```

   Where `<project>` is the namespace (project) that IBM Cloud Pak for AIOps is deployed in.

2. Locate the section for `elasticsearch` in the output, and calculate the additional resources that are needed for the duration of upgrade.

   The additional vCPU needed is `replicas` multiplied by `requests.cpu`, and the additional memory needed is `replicas` multiplied bu `requests.memory`.

   Example output for an `elasticsearch` section, where upgrade will need 15 additional vCPU (5 x 3) and 40960 Mi memory (5 x 8192).

```
elasticsearch:
     replicas: 5
     resources:
       requests:
         cpu: 3000m
         memory: 8192Mi
       limits:
         cpu: 6000m
         memory: 8192Mi
```

The migration causes approximately 10 minutes of downtime for the following IBM Cloud Pak for AIOps components: log integrations, ticket integrations, log anomaly model training, and the Insights Dashboard. If alert archiving to Elasticsearch is enabled on your deployment, then the downtime for the migration might be extended depending on the quantity of alerts stored.

During upgrade, you can run the following command to monitor the status of the migration:

```
oc describe installation -n <project>
```

Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

Example output for a migration in progress:

```
Conditions:
    Last Transition Time:            2024-10-29T16:58:55Z
    Message:                         Foreground Elasticsearch migration in progress
    Observed Generation:             2
    Reason:                          ForegroundMigrationInProgress
    Status:                          True
    Type:                            MigratingElastic
```

When migration is complete, **Message** has a value of **`Elasticsearch migration completed`**.

Note: Some integrations might be marked as **`Not Running`** while the migration is in progress. This is expected behavior, and the integrations must not be altered until the migration is complete.

After all services resume function, historic log data is migrated in the background. Historic log data is not accessible for training new models while this migration occurs. The duration of this background migration depends on the quantity of historic log data stored.

Upgrade procedure

Follow these steps to upgrade your online IBM Cloud Pak for AIOps deployment.

1. Ensure cluster readiness
2. Update the catalog
3. Update the operator subscription
4. Verify the deployment
5. Post upgrade actions

1. Ensure cluster readiness

Recommended: Take a backup before upgrading. For more information, see Backup and restore.

1. Ensure that your cluster still meets all of the prerequisites for deployment. For more information, see Planning.

   Ensure that your cluster has the additional resources that are required for upgrade, as outlined in Database migration during upgrade.

2. Run the IBM Cloud Pak for AIOps prerequisite checker script.

   Run the prerequisite checker script to ensure that your Red Hat OpenShift Container Platform cluster is correctly set up for an IBM Cloud Pak for AIOps upgrade.

   Download the prerequisite checker script from github.com/IBM, and run it with the following command:

   ```
   ./prereq.sh -n <project> --ignore-allocated
   ```

   Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

   Important: If you are installing on a multi-zone cluster, then also specify the **`-m`** flag to assess whether there are sufficient resources to withstand a zone outage.

   Note: The prerequisite checker script might show inadequate resources in the *Resource Summary* because the script does not account for resources already being in use by the upgrading deployment. This can be ignored, as can the following message: *[FAIL] Small or Large Profile Install Resources*.

   Example output:

   ```
   # ./prereq.sh -n cp4aiops --ignore-allocated
   [INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

   CLI: oc

```

3. Delete any evicted **connector-orchestrator** pods.
    1. From the **Project** list, select the project (namespace) that IBM Cloud Pak for AIOps is deployed in if your deployment is namespace scoped, or **openshift-operators** if your deployment has a cluster-wide scope.
    2. From the left menu, select **Workloads** > **Pods**, and search for **connector-orchestrator**.
    3. If there are any **connector-orchestrator** pods with a **STATUS** of **Evicted**, then select **Delete Pod** from the three dots menu at the end of the row.
4. Run the following command from the command line to ensure the safety of the Postgres database during upgrade.

    Important: Failure to run this step might lead to a complete loss of data.

    ```
    oc label clusters.postgresql.k8s.enterprisedb.io -n <project> $(oc get installations.orchestrator.aiops.ibm.com -n
    <project> -o jsonpath='{.items[].metadata.name}')-edb-postgres operator.ibm.com/opreq-do-not-uninstall='true'
    ```

    Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

2. Update the catalog

Update the **ibm-aiops-catalog** to use the v4.8.0 digest.

1. Go to **Administration** > **Cluster Settings** > **Configuration** > **OperatorHub** > **Sources**.

2. Select **ibm-aiops-catalog**, and then click the **YAML** tab.
3. Update the value of *image* to be **icr.io/cpopen/ibm-aiops-catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753**
4. Go to **Administration** > **Cluster Settings** > **Configuration** > **OperatorHub** > **Sources**.
5. Verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* CatalogSource objects are present, and that the image for *ibm-aiops-catalog* is **icr.io/cpopen/ibm-aiops-catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753**.

Note: During the upgrade of Cloud Pak for AIOps, Kubernetes jobs might fail and re-run. If a job succeeds on the second or third attempt, there can be one or two pods in **Error** state and one pod in the **Completed** state. If the job fails repeatedly, the attempt is abandoned, and the logs from failed pods are used to determine the cause of the failure. When you determine the cause for the failure, you can delete the job, and the operator can recreate it to reattempt the operations.

3. Update the operator subscription

Use the following steps to update the **spec.channel** value of the IBM Cloud Pak for AIOps subscription to v4.8.

1. Log in to your OpenShift cluster's console.
2. Select **Home** > **Search**.
3. From the **Project** list, select the project (namespace) that your IBM Cloud Pak for AIOps subscription is deployed in. This is your IBM Cloud Pak for AIOps project if your deployment is namespace scoped, or **openshift-operators** if your deployment has a cluster wide scope.
4. In the **Resources** list, select **SUB Subscription**. A list of subscriptions is displayed.
5. Click the subscription that has a **Name** of **ibm-aiops-orchestrator**. A new window with the subscription details for **ibm-aiops-orchestrator** is displayed.
6. Click the value in the **Update channel** box. A new window called **Change Subscription update channel** is displayed.
7. Change the channel to **v4.8** and click **Save**.
8. If you are installing with a cluster wide scope (**AllNamespaces** mode), use the following steps to refresh the connectors' secret:

   For more information about installation modes, see Operator installation mode.

   1. Select **Home** > **Search**.
   2. In the **Resources** list, select **Secret**. A list of secrets is displayed.
   3. Click the three dots at the end of the row that has a name of **cp4waiops-connectors-deploy-cert-secret**, and click **Delete Secret**.

4. Verify the deployment

Use the following procedure to check the status of your upgraded IBM Cloud Pak for AIOps deployment. It takes around 60-90 minutes for the upgrade to complete (subject to the speed with which images can be pulled).

1. Log in to your OpenShift cluster's console.
2. Click **Operators** > **Installed Operators**.
3. From the **Project** list, select the project (namespace) that IBM Cloud Pak for AIOps is deployed in if your deployment is namespace scoped, or **openshift-operators** if your deployment has a cluster-wide scope.
4. Locate **IBM Cloud Pak for AIOps** in the list, and verify that the annotation underneath it shows **4.8.0**.
5. Select **IBM Cloud Pak for AIOps** and then click the **IBM Cloud Pak for AIOps** tab.
6. Under **Installations**, look for the entry with the name that you specified for your IBM Cloud Pak for AIOps instance, and verify that it has a **Status** of *Phase: Running*, which means that your deployment is complete and successful.

   (Optional): If you want to see more detail about the status of your deployment's components, select the entry with the name that you specified for your IBM Cloud Pak for AIOps instance, and then switch to the **YAML** view. Scroll down to the **Status** section near the end of the YAML. A component's installation is complete and successful when the component has a value of **Ready**.

   Example YAML:

```
status:
  size: small
  customProfileConfigmap: aiops-custom-size-profile
  customProfileValidationStatus: >-
    Custom profile configmap not found, continue installation process without
    customization
  storageclasslargeblock: rook-ceph-rbd
  componentstatus:
    issueresolutioncore: Ready
    kafka: Ready
    aiopsanalyticsorchestrator: Ready
    aiopsedge: Ready
    tunnel: Ready
    lifecycleservice: Ready
    zenservice: Ready
```

```
    flinkcluster: Ready
    cluster: Ready
    elasticsearchcluster: Ready
    aiopsui: Ready
    redissentinel: Ready
    <...>
```

(Optional) You can also download and run a status checker script to see information about the status of your deployment. For more information about how to download and run the script, see github.com/IBM.

If the upgrade fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

Important: Wait for the deployment to enter a **Running** phase before continuing to the next step.

7. Verify that the database migration was successful.

    1. Switch to the **YAML** view. Scroll down to the **Status** section near the end of the YAML. Review the **conditions** section and verify that the **MigratingElastic** condition has a status of **False** and a reason of **MigrationComplete**.

        Example YAML for a successful migration:

        ```
        conditions:
        - lastTransitionTime: '2024-11-28T06:51:58Z'
          message: Elasticsearch migration completed
          observedGeneration: 3
          reason: MigrationComplete
          status: 'False'
          type: MigratingElastic
        ```

    2. Verify that all data is available in IBM Cloud Pak for AIOps as expected.

    Important: If database migration is not complete, review the troubleshooting entry Database migration is stuck. If this does not resolve the problem, then do not continue to the next step and contact IBM Support.

5. Post upgrade actions

1. Delete the persistent volumes that were used for storing data in Elasticsearch, the database that was migrated from.

    Run the following command:

    ```
    oc delete pvc -l app.kubernetes.io/managed-by=ibm-elastic-operator -n <project>
    ```

    Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

2. If you previously set up backup or restore on your deployment, then you must follow the instructions in Upgrading IBM Cloud Pak for AIOps backup and restore artifacts.

3. If the *EXPIRY_SECONDS* environment variable was set for configuring log anomaly alerts, the environment variable was not retained in the upgrade. After the upgrade is completed, set the environment variable again. For more information about setting the variable, see Configuring expiry time for log anomaly alerts.

4. If you have a metric integration configured that stops working after upgrade, then you must follow the instructions in After upgrade, a metric integration goes into a failed state.

Online upgrade of IBM Cloud Pak for AIOps (CLI method)

Use these instructions to upgrade an online deployment of IBM Cloud Pak® for AIOps 4.7.0 or later to 4.8.0.

Overview

This procedure is for deployments of IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform. This procedure can be used on an online deployment of IBM Cloud Pak for AIOps 4.7.0 or later, and can still be used if the deployment has had hotfixes applied.

You cannot use these instructions to upgrade deployments of IBM Cloud Pak for AIOps 4.6.1 or earlier. For more information, see Upgrade paths.

If you have an offline deployment of IBM Cloud Pak for AIOps on Red Hat OpenShift, follow the instructions in Upgrading IBM Cloud Pak for AIOps (offline).

If you have a deployment of IBM Cloud Pak for AIOps on Linux, follow the instructions in Online upgrade of IBM Cloud Pak for AIOps on Linux.

Important: If IBM® Netcool® Operations Insight® is deployed on the same cluster as IBM Cloud Pak for AIOps, ensure that Netcool Operations Insight is at version 1.6.13 or later before you upgrade IBM Cloud Pak for AIOps. Failure to do so may result in a broken Netcool Operations Insight deployment, as the IBM Cloud Pak for AIOps upgrade process updates a shared component that is used by both applications.

Before you begin

Notes:

- Ensure that you are on a version of Red Hat OpenShift that your current and target versions of IBM Cloud Pak for AIOps both support. If you already have a qualifying version of Red Hat OpenShift but you want to upgrade it, then complete the IBM Cloud Pak for AIOps upgrade first. For more information, see Guidance for upgrades that require an Red Hat OpenShift upgrade.
- Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).
- Red Hat OpenShift requires a user with `cluster-admin` privileges for the following operations:
  - Update the catalog
  - Update the operator subscription

Warnings:

- Custom patches, labels, and manual adjustments to IBM Cloud Pak for AIOps resources are lost when IBM Cloud Pak for AIOps is upgraded, and must be manually reapplied after upgrade. For more information, see Manual adjustments are not persisted.
- The upgrade cannot be removed or rolled back.
- If you previously increased the size of a PVC directly, then you must follow the correct procedure that is supplied in Resizing storage to ensure that the size is updated by the operator. Failure to do so before upgrading IBM Cloud Pak for AIOps causes the operator to attempt to restore a lower default value for the PVC, and causes an error in your IBM Cloud Pak for AIOps deployment.

Database migration during upgrade

The IBM Cloud Pak for AIOps 4.7.x to v4.8 upgrade process migrates the Elasticsearch database to an OpenSearch database.

Extra resources are needed during the upgrade, and are shown in the following table. These resources can be released after the upgrade is complete.

Table 1. Extra resources required during upgrade

Size	vCPU	Memory	Disk
Starter	2	8Gi	100Gi
Production	6	24Gi	300Gi

If IBM Sales representatives and Business Partners supplied you with a custom profile, then you must calculate the additional resource requirements as follows:

1. Run the following commands to view your custom profile ConfigMap.

   ```
   export PROJECT_CP4AIOPS=<project>
   oc get configmap -n "${PROJECT_CP4AIOPS}" $(oc get installation -n "${PROJECT_CP4AIOPS}" -o
   jsonpath='{.items[0].status.customProfileConfigmap}') -o yaml
   ```

   Where `<project>` is the namespace (project) that IBM Cloud Pak for AIOps is deployed in.

2. Locate the section for `elasticsearch` in the output, and calculate the additional resources that are needed for the duration of upgrade.

   The additional vCPU needed is `replicas` multiplied by `requests.cpu`, and the additional memory needed is `replicas` multiplied bu `requests.memory`.

   Example output for an `elasticsearch` section, where upgrade will need 15 additional vCPU (5 x 3) and 40960 Mi memory (5 x 8192).

   ```
   elasticsearch:
        replicas: 5
        resources:
          requests:
            cpu: 3000m
            memory: 8192Mi
          limits:
            cpu: 6000m
            memory: 8192Mi
   ```

The migration causes approximately 10 minutes of downtime for the following IBM Cloud Pak for AIOps components: log integrations, ticket integrations, log anomaly model training, and the Insights Dashboard. If alert archiving to Elasticsearch is enabled on your deployment, then the downtime for the migration might be extended depending on the quantity of alerts stored.

During upgrade, you can run the following command to monitor the status of the migration:

```
oc describe installation -n ${PROJECT_CP4AIOPS}
```

Example output for a migration in progress:

```
Conditions:
    Last Transition Time:            2024-10-29T16:58:55Z
    Message:                         Foreground Elasticsearch migration in progress
    Observed Generation:             2
    Reason:                          ForegroundMigrationInProgress
    Status:                          True
    Type:                            MigratingElastic
```

When migration is complete, **Message** has a value of `Elasticsearch migration completed`.

Note: Some integrations might be marked as `Not Running` while the migration is in progress. This is expected behavior, and the integrations must not be altered until the migration is complete.

After all services resume function, historic log data is migrated in the background. Historic log data is not accessible for training new models while this migration occurs. The duration of this background migration depends on the quantity of historic log data stored.

Upgrade procedure

Follow these steps to upgrade your online IBM Cloud Pak for AIOps deployment.

1. Ensure cluster readiness
2. Update the catalog
3. Update the operator subscription
4. Verify the deployment
5. Post upgrade actions

1. Ensure cluster readiness

Recommended: Take a backup before upgrading. For more information, see Backup and restore.

1. Ensure that your cluster still meets all of the prerequisites for deployment. For more information, see Planning.

   Ensure that your cluster has the additional resources that are required for upgrade, as outlined in Database migration during upgrade.

2. If you still have **waiops_var.sh** from when you installed IBM Cloud Pak for AIOps, then run the following command from the directory that the script is in, to set the environment variables that are used later.

   ```
   . ./waiops_var.sh
   ```

   If you do not have **waiops_var.sh**, then run the following commands to set the environment variables that you need for upgrade.

   ```
   export PROJECT_CP4AIOPS=<project>
   export INSTALL_MODE_NAMESPACE=<install_namespace>
   ```

   Where

   - **<project>** is the namespace (project) that your IBM Cloud Pak for AIOps subscription is deployed in.
   - **<install_namespace>** is ${PROJECT_CP4AIOPS} if your deployment is namespace scoped, or **openshift-operators** if your deployment has a cluster-wide scope.

3. Run the IBM Cloud Pak for AIOps prerequisite checker script.

   Run the prerequisite checker script to ensure that your Red Hat OpenShift Container Platform cluster is correctly set up for an IBM Cloud Pak for AIOps upgrade.

   Download the prerequisite checker script from github.com/IBM, and run it with the following command:

   ```
   ./prereq.sh -n ${PROJECT_CP4AIOPS} --ignore-allocated
   ```

   Important: If you are installing on a multi-zone cluster, then also specify the **-m** flag to assess whether there are sufficient resources to withstand a zone outage.

   Note: The prerequisite checker script might show inadequate resources in the *Resource Summary* because the script does not account for resources already being in use by the upgrading deployment. This can be ignored, as can the following message: *[FAIL] Small or Large Profile Install Resources*.

   Example output:

   ```
   # ./prereq.sh -n cp4aiops --ignore-allocated
   [INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

[INFO] ================================Prerequisite Checker Tool Summary================================
```

4. Delete any evicted **connector-orchestrator** pods.

    1. Run the following command to check if there are any evicted **connector-orchestrator** pods.

        ```
        oc get pods -n ${PROJECT_CP4AIOPS} | grep connector-orchestrator
        ```

    2. Cleanup any evicted connector-orchestrator pods.

        If the previous command returned any pods with a *STATUS* of **Evicted**, then run the following command to delete each of them.

        ```
        oc delete pod -n ${PROJECT_CP4AIOPS} <connector_orchestrator>
        ```

        Where **<connector_orchestrator>** is a pod returned in the previous step.

5. Run the following command to ensure the safety of the Postgres database during upgrade.

    Important: Failure to run this step might lead to a complete loss of data.

    ```
    oc label clusters.postgresql.k8s.enterprisedb.io -n $PROJECT_CP4AIOPS $(oc get
    installations.orchestrator.aiops.ibm.com -n $PROJECT_CP4AIOPS -o jsonpath='{.items[].metadata.name}')-edb-postgres
    operator.ibm.com/opreq-do-not-uninstall='true'
    ```

2. Update the catalog

Update the **ibm-aiops-catalog** to use the v4.8.0 digest.

1. Run the following command:

    ```
    cat << EOF | oc apply -f -
    apiVersion: operators.coreos.com/v1alpha1
    kind: CatalogSource
    metadata:
      name: ibm-aiops-catalog
      namespace: openshift-marketplace
    spec:
      displayName: ibm-aiops-catalog
      publisher: IBM Content
      sourceType: grpc
      image: icr.io/cpopen/ibm-aiops-catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
    EOF
    ```

2. Verify that the *ibm-aiops-catalog*, *ibm-cert-manager-catalog* and *ibm-licensing-catalog* CatalogSource objects are in the output that is returned by the following command:

    ```
    oc get CatalogSources -n openshift-marketplace
    ```

    Example output:

    ```
    oc get CatalogSources -n openshift-marketplace
    NAME                    DISPLAY                       TYPE   PUBLISHER   AGE
    ibm-aiops-catalog       ibm-aiops-catalog             grpc   IBM         2m
    ibm-cert-manager-catalog ibm-cert-manager             grpc   IBM         2m
    ibm-licensing-catalog    IBM License Service Catalog  grpc   IBM         2m
    ```

Note: During the upgrade of Cloud Pak for AIOps, Kubernetes jobs might fail and re-run. If a job succeeds on the second or third attempt, there can be one or two pods in `Error` state and one pod in the `Completed` state. If the job fails repeatedly, the attempt is abandoned, and the logs from failed pods are used to determine the cause of the failure. When you determine the cause for the failure, you can delete the job, and the operator can recreate it to reattempt the operations.

3. Update the operator subscription

1. Update the `spec.channel` value of the IBM Cloud Pak for AIOps subscription to the release that you want to upgrade to, v4.8.

   ```
   oc patch subscription.operators.coreos.com ibm-aiops-orchestrator -n ${INSTALL_MODE_NAMESPACE} --type=json -
   p='[{'op': 'replace', 'path': '/spec/channel', 'value': 'v4.8'}]'
   ```

2. If you are installing in `AllNamespaces` mode, run the following command to refresh the connectors' secret:

   ```
   oc delete secret cp4waiops-connectors-deploy-cert-secret -n "${PROJECT_CP4AIOPS}"
   ```

   For more information about installation modes, see Operator installation mode.

4. Verify the deployment

4.1 Check the deployment

Run the following command to check that the **PHASE** of your deployment is `Updating`.

```
oc get installations.orchestrator.aiops.ibm.com -n ${PROJECT_CP4AIOPS}
```

Example output:

```
NAME           PHASE     LICENSE    STORAGECLASS    STORAGECLASSLARGEBLOCK    AGE
ibm-cp-aiops   Updating  Accepted   rook-cephfs     rook-ceph-block           3m
```

It takes around 60-90 minutes for the upgrade to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **PHASE** of your installation changes to `Running`. If your installation phase does not change to `Running`, then use the following command to find out which components are not ready:

```
oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'Not Ready'
```

Example output:

```
lifecycleservice: Not Ready
zenservice: Not Ready
```

To see details about why a component is `Not Ready` run the following command, where `<component>` is the component that is not ready, for example `zenservice`.

```
oc get <component> -o yaml -n ${PROJECT_CP4AIOPS}
```

(Optional) You can also download and run a status checker script to see information about the status of your deployment. For more information about how to download and run the script, see github.com/IBM.

If the upgrade fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

Important: Wait for the deployment to enter a `Running` phase before continuing to the next step.

4.2 Verify database migration

1. Verify that the database migration was successful.

   Run the following command, and check that the `MigratingElastic` condition has a status of `false` and a reason of `MigrationCompleted`.

   ```
   oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'MigratingElastic' -B 5
   ```

   Example output for a successful migration:

   ```
   Conditions:
    - lastTransitionTime: "2024-10-29T17:16:55Z"
        message: Elasticsearch migration completed
        observedGeneration: 2
        reason: MigrationComplete
        status: "False"
        type: MigratingElastic
   ```

2. Verify that all data is available in IBM Cloud Pak for AIOps as expected.

Important: If database migration is not complete, review the troubleshooting entry Database migration is stuck. If this does not resolve the problem, then do not continue to the next step and contact IBM Support.

4.3 Check the version

Run the following command and check that the *VERSION* that is returned is `4.8.0`.

```
oc get csv -l operators.coreos.com/ibm-aiops-orchestrator.${INSTALL_MODE_NAMESPACE} -n ${INSTALL_MODE_NAMESPACE}
```

Example output:

```
oc get csv -l operators.coreos.com/ibm-aiops-orchestrator.cp4aiops -n cp4aiops
```

```
NAME                              DISPLAY                    VERSION  REPLACES                          PHASE
ibm-aiops-orchestrator.v4.8.0  IBM Cloud Pak for AIOps  4.8.0    ibm-aiops-orchestrator.v4.7.1  Succeeded
```

5. Post upgrade actions

1. Delete the persistent volumes that were used for storing data in Elasticsearch, the database that was migrated from.

   Run the following command:

   ```
   oc delete pvc -l app.kubernetes.io/managed-by=ibm-elastic-operator -n ${PROJECT_CP4AIOPS}
   ```

2. If you previously set up backup or restore on your deployment, then you must follow the instructions in Upgrading IBM Cloud Pak for AIOps backup and restore artifacts.

3. If the *EXPIRY_SECONDS* environment variable was set for configuring log anomaly alerts, the environment variable was not retained in the upgrade. After the upgrade is completed, set the environment variable again. For more information about setting the variable, see Configuring expiry time for log anomaly alerts.

4. If you have a metric integration configured that stops working after upgrade, then you must follow the instructions in After upgrade, a metric integration goes into a failed state.

Offline upgrade of IBM Cloud Pak for AIOps

Use these instructions to upgrade an offline deployment of IBM Cloud Pak® for AIOps 4.7.0 or later to 4.8.0.

Overview

This procedure is for deployments of IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform. This procedure can be used on an offline deployment of IBM Cloud Pak for AIOps 4.7.0 or later, and can still be used if the deployment has had hotfixes applied.

You cannot use these instructions to upgrade deployments of IBM Cloud Pak for AIOps 4.6.1 or earlier. For more information, see Upgrade paths.

If you have an online deployment of IBM Cloud Pak for AIOps on Red Hat OpenShift, follow the instructions in Upgrading IBM Cloud Pak for AIOps (online).

If you have a deployment of IBM Cloud Pak for AIOps on Linux®, follow the instructions in Offline upgrade of IBM Cloud Pak for AIOps on Linux.

Important: If IBM® Netcool® Operations Insight® is deployed on the same cluster as IBM Cloud Pak for AIOps, ensure that Netcool Operations Insight is at version 1.6.13 or later before you upgrade IBM Cloud Pak for AIOps. Failure to do so may result in a broken Netcool Operations Insight deployment, as the IBM Cloud Pak for AIOps upgrade process updates a shared component that is used by both applications.

Before you begin

Notes:

- Ensure that you are on a version of Red Hat OpenShift that your current and target versions of IBM Cloud Pak for AIOps both support. If you already have a qualifying version of Red Hat OpenShift but you want to upgrade it, then complete the IBM Cloud Pak for AIOps upgrade first. For more information, see Guidance for upgrades that require an Red Hat OpenShift upgrade.
- Ensure that you are logged in to your Red Hat® OpenShift® Container Platform cluster with `oc login` for any steps that use the OpenShift command-line interface (CLI).
- Red Hat OpenShift Container Platform requires a user with `cluster-admin` privileges for the following operations:
  - Mirror images
  - Update the catalog
  - Update the operator subscription

Warnings:

- Custom patches, labels, and manual adjustments to IBM Cloud Pak for AIOps resources are lost when IBM Cloud Pak for AIOps is upgraded, and must be manually reapplied after upgrade. For more information, see Manual adjustments are not persisted.
- The upgrade cannot be removed or rolled back.
- If you previously increased the size of a PVC directly, then you must follow the correct procedure that is supplied in Resizing storage to ensure that the size is updated by the operator. Failure to do so before upgrading IBM Cloud Pak for AIOps causes the operator to attempt to restore a lower default value for the PVC, and causes an error in your IBM Cloud Pak for AIOps deployment.

Database migration during upgrade

The IBM Cloud Pak for AIOps 4.7.x to v4.8 upgrade process migrates the Elasticsearch database to an OpenSearch database.

Extra resources are needed during the upgrade, and are shown in the following table. These resources can be released after the upgrade is complete.

Table 1. Extra resources required during upgrade

Size	vCPU	Memory	Disk

Size	vCPU	Memory	Disk
Starter	2	8Gi	100Gi
Production	6	24Gi	300Gi

If IBM Sales representatives and Business Partners supplied you with a custom profile, then you must calculate the additional resource requirements as follows:

1. Run the following commands to view your custom profile ConfigMap.

   ```
   export PROJECT_CP4AIOPS=<project>
   oc get configmap -n "${PROJECT_CP4AIOPS}" $(oc get installation -n "${PROJECT_CP4AIOPS}" -o
   jsonpath='{.items[0].status.customProfileConfigmap}') -o yaml
   ```

   Where **<project>** is the namespace (project) that IBM Cloud Pak for AIOps is deployed in.

2. Locate the section for **elasticsearch** in the output, and calculate the additional resources that are needed for the duration of upgrade.

   The additional vCPU needed is **replicas** multiplied by **requests.cpu**, and the additional memory needed is **replicas** multiplied bu **requests.memory**.

   Example output for an **elasticsearch** section, where upgrade will need 15 additional vCPU (5 x 3) and 40960 Mi memory (5 x 8192).

   ```
   elasticsearch:
        replicas: 5
        resources:
          requests:
            cpu: 3000m
            memory: 8192Mi
          limits:
            cpu: 6000m
            memory: 8192Mi
   ```

The migration causes approximately 10 minutes of downtime for the following IBM Cloud Pak for AIOps components: log integrations, ticket integrations, log anomaly model training, and the Insights Dashboard. If alert archiving to Elasticsearch is enabled on your deployment, then the downtime for the migration might be extended depending on the quantity of alerts stored.

During upgrade, you can run the following command to monitor the status of the migration:

```
oc describe installation -n ${PROJECT_CP4AIOPS}
```

Example output for a migration in progress:

```
Conditions:
    Last Transition Time:            2024-10-29T16:58:55Z
    Message:                         Foreground Elasticsearch migration in progress
    Observed Generation:             2
    Reason:                          ForegroundMigrationInProgress
    Status:                          True
    Type:                            MigratingElastic
```

When migration is complete, **Message** has a value of **Elasticsearch migration completed**.

Note: Some integrations might be marked as **Not Running** while the migration is in progress. This is expected behavior, and the integrations must not be altered until the migration is complete.

After all services resume function, historic log data is migrated in the background. Historic log data is not accessible for training new models while this migration occurs. The duration of this background migration depends on the quantity of historic log data stored.

Upgrade procedure

Follow these steps to upgrade your offline IBM Cloud Pak for AIOps deployment.

1. Ensure cluster readiness
2. Download CASE files
3. Mirror images
4. Update the catalog
5. Update the operator subscription
6. Verify the deployment
7. Post upgrade actions

1. Ensure cluster readiness

Recommended: Take a backup before upgrading. For more information, see Backup and restore.

1. Ensure that your cluster still meets all of the prerequisites for an air-gapped deployment.

   Ensure that your cluster has the additional resources that are required for upgrade, as outlined in Database migration during upgrade.

   Review the steps for your installation approach:

   - Bastion host: Prerequisites
   - Portable device: Prerequisites
2. Ensure that the IBM Catalog Management Plug-in for IBM Cloud Pak® (**ibm-pak-plugin**) is at the required level.

Important: `ibm-pak-plugin` v1.9 and lower cannot process the IBM Cloud Pak for AIOps 4.8.0 catalog. You must ensure that you have `ibm-pak-plugin` v1.10 or higher installed.

1. Check which version of `ibm-pak-plugin` you have installed.

   Run the following command on your bastion host, portable compute device, or connected compute device if you are using a portable storage device.

   ```
   oc ibm-pak --version
   ```

   Example output:

   ```
   oc ibm-pak --version
   v1.13.0
   ```

2. If the `ibm-pak-plugin` version is lower than v1.10.0, then you must download and install the most recent version.

   Follow the steps for your installation approach:

   - Bastion host: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.
   - Portable device: Install the IBM Catalog Management Plug-in for IBM Cloud Pak®.

3. Download scripts.

   1. Download the prerequisite checker script and copy it to your air-gapped environment.

      For more information about the script, including how to download and run it, see github.com/IBM.

   2. Download the IBM Cloud Pak for AIOps uninstall script, and copy it to your air-gapped environment.

      For more information about the script, including how to download and run it, see github.com/IBM.

   3. (Optional) Download the status checker script, and copy it to your air-gapped environment.

      For more information about the script, including how to download and run it, see github.com/IBM. The status checker script can be used in step 9. Verify the deployment to give information about the status of your deployment. The use of this script is optional, as status can be found directly from the `ibm-aiops-orchestrator` custom resource.

4. If you still have `waiops_var.sh` from when you installed IBM Cloud Pak for AIOps, then run the following command from the directory that the script is in, to set the environment variables that are used later.

   ```
   . ./waiops_var.sh
   ```

   If you do not have `waiops_var.sh`, then run the following commands to set the environment variables that you need for upgrade.

   ```
   export PROJECT_CP4AIOPS=<project>
   export INSTALL_MODE_NAMESPACE=<install_namespace>
   export CATALOG_SRC_CP4AIOPS=ibm-aiops-catalog
   ```

   Where

   - `<project>` is the namespace (project) that your IBM Cloud Pak for AIOps subscription is deployed in.
   - `<install_namespace>` is ${PROJECT_CP4AIOPS} if your deployment is namespace scoped, or `openshift-operators` if your deployment has a cluster-wide scope.

5. Run the IBM Cloud Pak for AIOps prerequisite checker script.

   Run the prerequisite checker script to ensure that your Red Hat OpenShift Container Platform cluster is correctly set up for an IBM Cloud Pak for AIOps upgrade.

   Download the prerequisite checker script from github.com/IBM, and run it with the following command:

   ```
   ./prereq.sh -n ${PROJECT_CP4AIOPS} --ignore-allocated
   ```

   Important: If you are installing on a multi-zone cluster, then also specify the `-m` flag to assess whether there are sufficient resources to withstand a zone outage.

   Note: The prerequisite checker script might show inadequate resources in the *Resource Summary* because the script does not account for resources already being in use by the upgrading deployment. This can be ignored, as can the following message: *[FAIL] Small or Large Profile Install Resources*.

   Example output:

   ```
   # ./prereq.sh -n cp4aiops --ignore-allocated

   [INFO] Starting IBM Cloud Pak for AIOps prerequisite checker v4.8...

6. Delete any evicted **connector-orchestrator** pods.

    1. Run the following command to check if there are any evicted **connector-orchestrator** pods.

        ```
        oc get pods -n ${PROJECT_CP4AIOPS} | grep connector-orchestrator
        ```

    2. Cleanup any evicted connector-orchestrator pods.

        If the previous command returned any pods with a *STATUS* of **Evicted**, then run the following command to delete each of them.

        ```
        oc delete pod -n ${PROJECT_CP4AIOPS} <connector_orchestrator>
        ```

        Where **<connector_orchestrator>** is a pod returned in the previous step.

7. Run the following command to ensure the safety of the Postgres database during upgrade.

    Important: Failure to run this step might lead to a complete loss of data.

    ```
    oc label clusters.postgresql.k8s.enterprisedb.io -n $PROJECT_CP4AIOPS $(oc get
    installations.orchestrator.aiops.ibm.com -n $PROJECT_CP4AIOPS -o jsonpath='{.items[].metadata.name}')-edb-postgres
    operator.ibm.com/opreq-do-not-uninstall='true'
    ```

2. Download CASE files

On your OpenShift cluster, rerun step 2 of the air-gap installation procedure **Download CASE files** to download the latest CASE files.

Follow the steps for your installation approach:

- Bastion host: Download the CASE
- Portable device: Download the CASE

3. Mirror images

Rerun step 3 of the air-gap installation procedure to mirror the updated images to the offline registry.

Follow the steps for your installation approach:

- Bastion host: Mirror images
- Portable device: Mirror images

4. Update the catalog

1. Rerun step 5.2 of the air-gap installation procedure **Create the catalog source** to update your catalog source.

   Follow the steps for your installation approach:

   - Bastion host: Create the catalog source
   - Portable device: Create the catalog source

2. From IBM Cloud Pak for AIOps 4.8.0, IBM Cloud Pak® foundational services Cert Manager and License Service are deployed using their own independent catalogs, and a new catalog called **ibm-aiops-catalog** is used for the remaining IBM Cloud Pak for AIOps operators. You must migrate your subscriptions to use the new catalogs.

   Run the following script from the command line:

```
# New catalog name to migrate to
target="ibm-aiops-catalog"

# Previous catalog names to migrate from
catalogs="""aiops-analytics-operator-catalog
aiops-lifecycle-operator-catalog
cloud-native-postgresql-catalog
ibm-aiops-appconnect-catalog
ibm-aiops-ir-core-operators
ibm-aiops-opencontent-flink-catalog
ibm-asm-catalog ibm-cp-waiops-catalog
ibm-cp-waiops-elastic-catalog
ibm-cp-waiops-flink-catalog
ibm-aiopsedge-case
ibm-redis-cp-operator-catalog
ibm-secure-tunnel-operator-catalog
ibm-watson-ai-manager-catalog
ibm-watson-aiops-ui-catalog
opencloud-operators"""

echo "Getting all subscriptions..."
all_subs=$(oc get subscriptions.operators.coreos.com --no-headers -n ${PROJECT_CP4AIOPS})

for catalog in $catalogs; do
  subs=$(echo "$all_subs" | awk -v c=$catalog '$3 == c {print $1}' -)
  if [[ -n $subs ]]; then
    echo "Updating catalog source for subscription $subs from $catalog to $target"
    oc patch subscriptions.operators.coreos.com $subs -n ${PROJECT_CP4AIOPS} --type=json --patch='[{"op": "replace",
"path": "/spec/source", "value": '$target'}]'
  fi

  oc delete catalogsource $catalog -n openshift-marketplace
done
```

5. Update the operator subscription

1. Run the following command to update the IBM Cloud Pak for AIOps subscription to use the new channel, v4.8.

```
oc patch subscription.operators.coreos.com ibm-aiops-orchestrator -n ${INSTALL_MODE_NAMESPACE} --type=json -
p='[{'op': 'replace', 'path': '/spec/channel', 'value': 'v4.8'}]'
```

2. If you are installing in **AllNamespaces** mode, run the following command to refresh the connectors' secret:

```
oc delete secret cp4waiops-connectors-deploy-cert-secret -n "${PROJECT_CP4AIOPS}"
```

   For more information about installation modes, see Operator installation mode.

6. Verify the deployment

6.1 Check the deployment

Run the following command to check that the **PHASE** of your deployment is **Updating**.

```
oc get installations.orchestrator.aiops.ibm.com -n ${PROJECT_CP4AIOPS}
```

Example output:

```
NAME           PHASE     LICENSE    STORAGECLASS    STORAGECLASSLARGEBLOCK    AGE
ibm-cp-aiops   Updating  Accepted   rook-cephfs     rook-ceph-block           3m
```

It takes around 60-90 minutes for the upgrade to complete (subject to the speed with which images can be pulled). When installation is complete and successful, the **PHASE** of your installation changes to `Running`. If your installation phase does not change to `Running`, then use the following command to find out which components are not ready:

```
oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'Not Ready'
```

Example output:

```
lifecycleservice: Not Ready
zenservice: Not Ready
```

To see details about why a component is `Not Ready` run the following command, where `<component>` is the component that is not ready, for example `zenservice`.

```
oc get <component> -o yaml -n ${PROJECT_CP4AIOPS}
```

(Optional) If you downloaded the status checker script earlier in step 1.5 Ensure cluster readiness, then you can also run this script to see information about the status of your deployment.

If the upgrade or migration fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade and Known Issues to help you identify any installation problems.

Important: Wait for the deployment to enter a `Running` phase before continuing to the next step.

6.2 Verify database migration

1. Verify that the database migration was successful.

   Run the following command, and check that the `MigratingElastic` condition has a status of `false` and a reason of `MigrationCompleted`.

   ```
   oc get installation.orchestrator.aiops.ibm.com -o yaml -n ${PROJECT_CP4AIOPS} | grep 'MigratingElastic' -B 5
   ```

   Example output for a successful migration:

   ```
   Conditions:
    - lastTransitionTime: "2024-10-29T17:16:55Z"
        message: Elasticsearch migration completed
        observedGeneration: 2
        reason: MigrationComplete
        status: "False"
        type: MigratingElastic
   ```

2. Verify that all data is available in IBM Cloud Pak for AIOps as expected.

Important: If database migration is not complete, review the troubleshooting entry Database migration is stuck. If this does not resolve the problem, then do not continue to the next step and contact IBM Support.

6.3 Check the version

Run the following command and check that the *VERSION* that is returned is `4.8.0`.

```
oc get csv -l operators.coreos.com/ibm-aiops-orchestrator.${INSTALL_MODE_NAMESPACE} -n ${INSTALL_MODE_NAMESPACE}
```

Example output:

```
oc get csv -l operators.coreos.com/ibm-aiops-orchestrator.cp4aiops -n cp4aiops
NAME                           DISPLAY                  VERSION  REPLACES                       PHASE
ibm-aiops-orchestrator.v4.8.0  IBM Cloud Pak for AIOps  4.8.0    ibm-aiops-orchestrator.v4.7.1  Succeeded
```

7. Post upgrade actions

1. Delete the persistent volumes that were used for storing data in Elasticsearch, the database that was migrated from.

   Run the following command:

   ```
   oc delete pvc -l app.kubernetes.io/managed-by=ibm-elastic-operator -n ${PROJECT_CP4AIOPS}
   ```

2. If you previously set up backup or restore on your deployment, then you must follow the instructions in Upgrading IBM Cloud Pak for AIOps backup and restore artifacts.

3. If the *EXPIRY_SECONDS* environment variable was set for configuring log anomaly alerts, the environment variable was not retained in the upgrade. After the upgrade is completed, set the environment variable again. For more information about setting the variable, see Configuring expiry time for log anomaly alerts.

4. If you have a metric integration configured that stops working after upgrade, then you must follow the instructions in After upgrade, a metric integration goes into a failed state.

Administering IBM Cloud Pak for AIOps on OpenShift

After you install IBM Cloud Pak® for AIOps, you can access several options for administering and customizing your deployment.

- Backup and restore
- Configuring topology resources for production
- Health checks and monitoring
- Managing certificates
- Multi-zone rebalancing
- Resizing storage
- Restarting the environment
- Secure Tunnels
- Updating the deployment type

See also Cloud Pak administration

To gather data about your deployment for support or troubleshooting purposes, you can install and run the `MustGather` script:

- MustGather tool

Back up and restore (IBM Cloud Pak for AIOps on OpenShift)

You can use Red Hat OpenShift APIs for Data Protection (OADP) or IBM Fusion to backup and restore a deployment of IBM Cloud Pak for AIOps on Red Hat® OpenShift® Container Platform.

Backup and restore with IBM Fusion offers an incremental online backup with a console based user experience, which backup and restore with OADP does not. Backup and restore with IBM Fusion requires an IBM Fusion license. For more information, see the following topics:

- Backup and restore with OADP
- Backup and restore with Fusion (Cold Standby DR)

Backup and restore Cloud Pak for AIOps with OADP

Learn how to back up and restore IBM Cloud Pak for AIOps, such as for recovering from a disaster like a complete data center outage.

- Overview
- Planning
- Backup process
- Restore process
- Components

Overview

IBM Cloud Pak for AIOps backup and restore is based on the storage and database backup of critical datastores, cluster resources, and component data and settings. With the backup and restore feature, you can recover your services to a previous point in time backup to recover from data corruption, system failures, or user errors.

You can also use the backup and restore feature as a means of copying data from one cluster to another, or from one environment into another, such as for disaster recovery purposes.

If you are using backup data to restore environments on a new cluster in another data center, your recovery time objective (RTO) and recovery point objective (RPO) must be sufficient for this usage.

IBM Cloud Pak for AIOps uses the *OpenShift APIs for Data Protection* (OADP) to backup data to object storage. In the case of a failure, the APIs and OADP are used to restore data from the backups.

For more information about these tools, see:

- OpenShift APIs for Data Protection (OADP) features
- Velero documentation

Planning for backup and restore

When you are planning your IBM Cloud Pak for AIOps backup and restore strategy, consider what hardware requirements are needed for backing up your environment:

- You need to install the backup and restore tools in the Red Hat OpenShift Container Platform cluster. These tools include the OpenShift APIs for Data Protection (OADP) which creates required CRs such as `DataProtectionApplication` and `BackupStorageLocation`. You need to configure the OpenShift APIs and OADP with the appropriate object storage for storing your backups. This object storage must support RWX (read-write-execute) mode.
- You can backup both smaller starter and larger production sized cluster deployments.
- You can use backed up data to restore data to the existing cluster where the data was backed up, or to a new cluster.
- A restored cluster should have the same size and high availability level as the original cluster.
- Data is copied and stored in object Storage as part of the backup process. During a restoration, the same data is fetched and restored.

Notes:

- The backup and restore processes can take time. Using a backup to restore data or configurations is most useful when your recover time objective (RTO) and recovery point objectives (RPO) are met.
- As your data grows, the size of your backup storage might need to grow.
- A backup and restore of Red Hat OpenShift Container Platform or ETCD is not completed as part of the IBM Cloud Pak for AIOps backup and restore feature.
- Configure the duration between your backups to be less than your RPO. By default, the RPO is 12 hours, which requires backups to run once every 12 hours. The default RTO is 4 hours.
- The Flink state for log anomaly is not backed up and any training is lost during a failure or disaster. You need to run the training again after you recover from the disaster.
- If you upgrade your deployment, you must setup back and restore again. For more information, see Upgrading IBM Cloud Pak for AIOps backup and restore artifacts.
- A backup and restore of the optional product IBM Cognos® Analytics is not completed as part of the IBM Cloud Pak for AIOps backup and restore feature.
- If you perform backup and restore for Cloud Pak for AIOps with OADP, then IBM Spectrum Fusion must not be installed on source and target clusters or else the backup and restore procedures might fail.

Backup process

The IBM Cloud Pak® for AIOps backup process is capable of backing up data for both IBM Cloud Pak for AIOps and Infrastructure Automation. The backup of data is completed by backing up the datastores that include IBM Cloud Pak for AIOps data, and if available, Infrastructure Automation data. Some datastores are backed up and restored in their entirety. Other datastores are backed up and restored depending on a particular component need.

The following table shows the IBM Cloud Pak® for AIOps datastores and persistent volume claims (PVCs) that are backed up:

Table. Backed up datastores

Datastores	Backup type	Example backup PVC name	Access mode
`CouchDB`	Volume backup	data-c-example-couchdbcluster-m-0	ReadWriteOnce
`Cassandra`	Data export	back-aiops-topology-cassandra-0	ReadWriteOnce
`EDB Postgres`	Data export	postgres-backup-data	ReadWriteOnce
`Minio`	Volume backup	export-aimanager-ibm-minio-0	ReadWriteOnce
`ElasticSearch`	Partial (Elastic native volume backup used)	aiops-ibm-elasticsearch-es-server-snap	ReadWriteMany
`Kafka`	None		
`Flink`	None		
`metastore`	Data export	metastore-backup-data	ReadWriteOnce
Other resources like `Tunnel` custom resource	Volume export	other-resources-backup-data	ReadWriteOnce

The following table shows the backed up Kubernetes resources:

Table. Backed up resources

Backup resource name	Resource type
dummy-db	pod
es-backup	pod
backup-back-aiops-topology-cassandra	pod
backup-data-c-example-couchdbcluster-m	pod
backup-export-aimanager-ibm-minio	pod
backup-metastore	pod
backup-postgres	pod
backup-other-resources	pod
aiops-ir-core-model-secret	secret
aimanager-ibm-minio-access-secret	secret
zen-secrets-aes-key	secret
BundleManifest	custom resource
ConnectorConfiguration	custom resource
ConnectorSchemas	custom resource

The backup process is run by custom backup-jobs. When the backup job runs, pods can be scaled down to ensure consistent backups are created. The backup job calls OADP to back up Kubernetes resources and volumes. Native backup scripts are run to back up datastores. The backup job then scales up pods to match their state before the backup process began. Datastores that have a selective backup types are backed up only when the datastore is updated since the previous backup.

For more information about the backup process, see:

- Backing up IBM Cloud Pak for AIOps data.
- Backing up Infrastructure Automation data.

Notes: For Elasticsearch, the backup and restore process completes incremental backup snapshots of Elasticsearch. While creating the snapshot, Elasticsearch analyses the list of the index files that are stored in the repository that is being backed up and copies only the files that were created or changed since the last snapshot occurred. This process allows you to have multiple snapshots stored in a compact form.

Component data backups

When the backup process runs for IBM Cloud Pak for AIOps, data for the following components are backed up. This data includes cluster resources, such as Secrets, Pods, CRDs, CRs, PVCs, and PVs.

- **AI model management**

log anomaly detection and metric anomaly detection templates and models are backed up. In addition, model and training metadata, secrets, and configurations are backed up. If this data is not backed up and is lost during a disaster, you cannot run training until you collect training data again. In addition your models and templates can be lost, which can prevent principal component analysis (PCA) from running until you run training to rebuild the models. You might not be able to recreate historical model if data loss occurs.

For similar ticket analysis, the trained models are backed up.

Notes

- Component data, such as for log anomaly detections or similar ticket analysis, is not encrypted when it is backed up.
- Raw data and data-in-transit, such as Kafka topics, are not backed up.
- logtrain indices and other training data is not backed up other than training metadata.
- Before you run the backup process, stop all training that is in progress. Do not start or restart training until the backup process is completed

- **Change risk**

  For change risk, risk models, risk assessments, incidents, and ticket data assets are backed up.

  Notes

  - Data-in-transit is not backed up.
  - If change or incident ticket data loss occurs, you might need to run data collection again from your ticketing system.
  - In change risk model loss occurs, you need to recreate the lost models by using the IBM Cloud Pak for AIOps IBM Cloud Pak for AIOps console. Historical models can be difficult to re-create.
  - In the case of risk assessments loss, there is no way to reconstruct the assessments.
- **Automations** (Runbooks)

  For Automations, runbooks, automations, execution records, and configurations are backed up.

- **Integrations**

  Integration CRs, Secrets, and configurations, are backed up.

- **Event & Topology analytics**

  Probable cause data, Topology data, configurations and indexed data, is backed up.

- **Policy management**

  For policy management, operational policies and policy run time statistics (last run, count of executions) are backed up.

- **Secure Tunnel**

  Tunnel CRs, which represent connections, application mappings, and templates are backed up.

Restore process

To run the restore process, you first need to create a new cluster and install the required prerequisites on the cluster. The prerequisites include installing the required CLI tools, creating the storage classes, and updating the **`bcdr/common/aiops-config.json`** and **`bcdr/restore/restore-data.json`** files with the required configuration values. Then you need to configure OADP to point to the same s3 storage where the backup is located.

You then need to create the required namespaces for IBM Cloud Pak® for AIOps by running the **`restore-namespace.sh`** job. This script creates only the namespaces and namespace metadata, not the contents of the namespace. This namespace restore is needed because the metadata contains SELinux settings that must match the settings from the corresponding namespaces on the cluster where you took the backup.

Then, you need to complete the installation of IBM Cloud Pak for AIOps and create an IBM Cloud Pak for AIOps instance. With the instance created and OADP configured, you can run the OADP restore jobs to populate the instance. When the jobs complete you need to run any other post restore tasks that you need to complete.

Note: OADP does not support the overriding of resources during the restore. The restoration of resources already existing in the cluster are skipped. If this occurs, sync the existing resources and create only the resources that were not restored instead of creating a new resources Operator.

For more information about the restore process, see Restoring IBM Cloud Pak for AIOps.

Procedures for backing up and restoring IBM Cloud Pak for AIOps

- Installing the backup and restore tools
- Configuring ODF as backup storage for OADP
- Backing up IBM Cloud Pak for AIOps
- Restoring IBM Cloud Pak for AIOps
- Upgrading IBM Cloud Pak for AIOps backup and restore artifacts

Installing the backup and restore tools

Learn how to install the tools that are required for the backup and restore of IBM Cloud Pak for AIOps.

You need to install the Red Hat OpenShift APIs for Data Protection (OADP). OADP provides default Velero plug-ins that are integrated with storage providers to support backup operations.

Note: The backup and restore tools for IBM Cloud Pak for AIOps are the same as the tools for backing up and restoring Infrastructure Automation. If you have the tools installed for Infrastructure Automation, you do not need to complete the following procedure.

Prerequisites

- Provision the object storage (S3 bucket) for storing your backups. The backup process moves backup files to an S3 bucket, which must be in an S3 compatible location, such as Amazon Web Services (AWS).
- Ensure that the following command line tools are installed on your workstation:
  - `oc`
  - `jq`
  - `git`
- Ensure that you are logged in to your Red Hat® OpenShift® Container Platform cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).

Procedure

1. Install the Velero client CLI
2. Install OpenShift API for Data Protection (OADP)
3. (Offline deployments only) Mirror the backup and restore image

1. Install the Velero client CLI

Install the Velero client CLI on the workstation that you plan to use to run the scripts for backing up and restoring the cluster.

1. Run the following command to download the Velero CLI client:

   ```
   curl -LO https://github.com/vmware-tanzu/velero/releases/download/v1.12.3/velero-v1.12.3-linux-amd64.tar.gz
   ```

2. Extract the tarball:

   ```
   tar -xzf velero-v1.12.3-linux-amd64.tar.gz
   ```

3. Move the extracted velero binary to `/usr/local/bin`:

   ```
   mv velero-v1.12.3-linux-amd64/velero /usr/local/bin/velero
   ```

4. Run the following command to verify the installation.

   ```
   velero version
   ```

   Example output:

   ```
   Client:
    Version: v1.12.3
    Git commit: 06d12dec4030703cb46b2699ca434cdabd9edbb0
   velero version
   ```

2. Install Red Hat OpenShift APIs for Data Protection (OADP)

For more information, see the Red Hat OpenShift documentation About installing OADP.

As a convenience, if you are using S3 buckets on AWS, you can use the installation script `install-oadp.sh` in this section to simplify the process.

If you are using Red Hat® OpenShift® Data Foundation for your backup storage, follow the instructions in Configuring ODF as backup storage for OADP.

If you are not using Red Hat® OpenShift® Data Foundation for your backup storage, use the following steps:

1. Clone the IBM Cloud Pak for AIOps samples GitHub repository that includes the backup and restore scripts. Clone this repository by running the following command:

   ```
   git clone https://github.com/IBM/cp4waiops-samples.git
   ```

   If you have an offline (air-gapped) deployment of IBM Cloud Pak for AIOps, then copy the cloned scripts to your air-gapped environment.

2. Update the installation files.

   1. Change to the `install` directory where the backup and restore scripts are downloaded.

      ```
      cd <Path>/bcdr/4.8.0/install
      ```

      Where `<Path>` is the path to where you cloned the IBM Cloud Pak for AIOps backup and restore scripts.

   2. Edit the `install-oadp-config.json` script. Configure the following settings:

      - `aws_access_key_id` - Access key ID to connect to your object storage S3 bucket.
      - `aws_secret_access_key` - Secret access key to connect to your S3 bucket.
      - `bucket_name` - Name of the S3 bucket where backup data will be stored.
      - `bucket_region` - Region where the S3 bucket is deployed.

- `namespace` - Namespace name in which you want to deploy OADP. If the namespace does not exist, it is created when you run the OADP installation script.
- `backup_label` - Label for creating a folder structure to organize sets of backups together.

3. Edit the `install-oadp.sh` script.

   If your version of Red Hat OpenShift is higher than v4.15, update `channel: stable-1.3` to `channel: stable-1.4`.

   Example excerpt:

   ```
   spec:
     channel: stable-1.4
     installPlanApproval: Automatic
     name: redhat-oadp-operator
     source: redhat-operators
     sourceNamespace: openshift-marketplace
   ```

3. Run the OADP installation script:

   ```
   nohup ./install-oadp.sh > install-oadp.log &
   ```

4. Check the logs by running the following command:

   ```
   tail -f install-oadp.log
   ```

5. Export an environment variable with the Velero namespace.

   ```
   export OADP_NAMESPACE=<oadpNamespace>
   ```

   Where `<oadpNamespace>` is the namespace where OADP is installed.

6. Check the Velero pods status by running the following command:

   ```
   oc get pods -n ${OADP_NAMESPACE}
   ```

   The Velero and Restic pods should be in a running state.

7. Check the status of the `backupStorageLocation` by running the following command:

   ```
   oc get backupStorageLocation -n ${OADP_NAMESPACE}
   ```

   The `backupStorageLocation` needs to be in an available status.

3. (Offline deployments only) Mirror the backup and restore image

If the deployment that you are backing up or restoring to is an offline (air-gapped) deployment, then you must copy the backup and restore image to a registry that is available to your air-gapped environment. You can do this by using either a bastion host or a portable device. For background information on offline (air-gapped) deployments, see Installing IBM Cloud Pak for AIOps in an air-gapped environment (offline).

Prerequisites:

- The host that you are running the mirror from must allow access to `icr.io` on port 443.
- You must have a target registry available to mirror the backup and restore image into. The target registry must adhere to the requirements in Set up a target registry.

Follow the instructions in Mirroring with a bastion host or Mirroring with a portable device.

Mirroring with a bastion host

1. Set environment variables.

   ```
   export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
   export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   export TARGET_REGISTRY_USER=<username>
   export TARGET_REGISTRY_PASSWORD=<password>
   export BCDR_IMAGE=<bcdr_image>
   export BCDR_UTILS_IMAGE=cp4waiops-bcdr-utils@sha256:1db594ad10da9c7049367b5dd4373e86af7e6bcb875758022e2e743c83cf486f
   export AIOPS_NAMESPACE=<aiops_namespace>
   ```

   Where

   - `<bcdr_image>` is the name of the backup and restore image, as given in the backup helm chart `values.yaml` file, in the form `cp4waiops-bcdr@{digest}`. An example value for BCDR_IMAGE is `cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355`.
   - `<aiops_namespace>` is the namespace that IBM Cloud Pak for AIOps is deployed in.

   If your bastion host must connect to the internet through a proxy, then also set the following environment variables:

   ```
   export https_proxy=http://proxy-server-hostname:port
   export http_proxy=http://proxy-server-hostname:port
   ```

2. Authenticate with the target registry.

   You do not need to authenticate with the IBM Entitled Registry, as the image that you require for backup and restore is freely available.

You need to authenticate with the target registry to enable the `oc image mirror` command to push the image to your target registry. Log in to your target registry to generate an authentication file containing the registry credentials, and then create an environment variable that has the location of the authentication file.

Run the following commands:

```
podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD}
export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
```

Note: The authentication file is usually at `${XDG_RUNTIME_DIR}/containers/auth.json`. For more information, see the Options section in the Podman documentation.

3. Mirror the image.

   Connect the bastion host to the internet and disconnect if from the air-gapped environment. Then run the following command to mirror the backup and restore image to the target registry:

   ```
   oc image mirror icr.io/cpopen/cp4waiops/${BCDR_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_IMAGE} -a
   ${REGISTRY_AUTH_FILE} --insecure
   oc image mirror icr.io/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_UTILS_IMAGE}
   -a ${REGISTRY_AUTH_FILE} --insecure
   ```

4. Create the `ImageContentSoucePolicy`.

   1. Switch to the namespace that IBM Cloud Pak for AIOps is deployed in.

      ```
      oc project ${AIOPS_NAMESPACE}
      ```

   2. Run the following command to create the `ImageContentSourcePolicy`.

      ```
      cat << EOF | oc apply -f -
      apiVersion: operator.openshift.io/v1alpha1
      kind: ImageContentSourcePolicy
      metadata:
       name: bcdr-mirrors
      spec:
       repositoryDigestMirrors:
        - mirrors:
          - ${TARGET_REGISTRY}/cpopen/cp4waiops/
          source: icr.io/cpopen/cp4waiops/
      EOF
      ```

Mirroring with a portable device

If you are using a portable storage device, then connect it to a host with access to the internet. If you are using a portable compute device, then connect it to the internet. Run the following steps.

1. Set environment variables.

   ```
   export IMAGE_PATH=<image-path>
   export BCDR_IMAGE=<bcdr_image>
   export BCDR_UTILS_IMAGE=cp4waiops-bcdr-utils@sha256:1db594ad10da9c7049367b5dd4373e86af7e6bcb875758022e2e743c83cf486f
   ```

   Where

   - `<image_path>` is the directory where you want the image to be stored.
   - `<bcdr_image>` is the name of the backup and restore image, as given in the backup helm chart `values.yaml` file, in the form `cp4waiops-bcdr@{digest}`. An example value for BCDR_IMAGE is `cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355`.

   If your device must connect to the internet through a proxy, then also set the following environment variables:

   ```
   export https_proxy=http://proxy-server-hostname:port
   export http_proxy=http://proxy-server-hostname:port
   ```

2. Mirror the images to the file system on your portable device.

   You do not need to authenticate with the IBM Entitled Registry, as the image that you require for backup and restore is freely available. Run the following command to mirror the image from the IBM Entitled Registry to the file system on your portable device.

   ```
   oc image mirror \
   icr.io/cpopen/cp4waiops/${BCDR_IMAGE} file://cpopen/cp4waiops/${BCDR_IMAGE} \
   --filter-by-os '.*' \
   --insecure \
   --skip-multiple-scopes \
   --dir "${IMAGE_PATH}" \
   --max-per-registry=1

   oc image mirror \
   icr.io/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} file://cpopen/cp4waiops/${BCDR_UTILS_IMAGE} \
   --filter-by-os '.*' \
   --insecure \
   --skip-multiple-scopes \
   --dir "${IMAGE_PATH}" \
   --max-per-registry=1
   ```

3. Setup the file system in the air-gapped environment.

   1. (Portable storage device only) Copy files to the air-gapped environment

If you are using a portable storage device, you must copy the files at $IMAGE_PATH on the portable storage device to a local compute device in the air-gapped environment that has access to the target registry. If you are using a portable compute device, then these files are already present, and you can proceed to the next step.

2. Disconnect the device that has your file system (the portable compute device or the local compute device) from the internet and connect it to the air-gapped environment.

3. Set environment variables on the device in the air-gapped environment that has access to the target registry.

   If you are using a portable compute device, then set the following environment variables on it. If you are using a portable storage device, then set the following environment variables on your local compute device within the air-gapped environment.

   ```
   export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
   export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   export TARGET_REGISTRY_USER=<username>
   export TARGET_REGISTRY_PASSWORD=<password>
   export IMAGE_PATH=<image_path>
   export BCDR_IMAGE=<bcdr_image>
   export BCDR_UTILS_IMAGE=cp4waiops-bcdr-
   utils@sha256:1db594ad10da9c7049367b5dd4373e86af7e6bcb875758022e2e743c83cf486f
   export AIOPS_NAMESPACE=<aiops_namespace>
   ```

   Where

   - **<bcdr_image>** is the name of the backup and restore image, as given in the backup helm chart **values.yaml** file, in the form **cp4waiops-bcdr@{digest}**. An example value for BCDR_IMAGE is **cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355**.
   - **<aiops_namespace>** is the namespace that IBM Cloud Pak for AIOps is deployed in.

4. Authenticate with the target registry.

   Authenticate with the target registry in the air-gapped environment that you are mirroring the image into. You need to authenticate with the target registry to enable the **oc image mirror** command to push the image to your target registry. Log in to your target registry to generate an authentication file containing the registry credentials, and then create an environment variable that has the location of the authentication file.

   Run the following commands:

   ```
   podman login ${TARGET_REGISTRY} -u ${TARGET_REGISTRY_USER} -p ${TARGET_REGISTRY_PASSWORD}
   export REGISTRY_AUTH_FILE=${XDG_RUNTIME_DIR}/containers/auth.json
   ```

   Note: The authentication file is usually at **${XDG_RUNTIME_DIR}/containers/auth.json**. For more information, see the Options section in the Podman documentation.

5. Mirror the images to the target registry from the file system.

   Run the following command on the device that has your file system (the portable compute device or the local compute device) to copy the image from the file system to the $TARGET_REGISTRY. Your device with the file system must be connected to both the target registry and the Red Hat® OpenShift® Container Platform cluster that you want to backup or restore IBM Cloud Pak for AIOps on.

   ```
   oc image mirror \
   file://cpopen/cp4waiops/${BCDR_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_IMAGE} \
   --from-dir "${IMAGE_PATH}" \
   -a ${REGISTRY_AUTH_FILE} \
   --filter-by-os '.*' \
   --insecure  \
   --skip-multiple-scopes \
   --max-per-registry=1

   oc image mirror \
   file://cpopen/cp4waiops/${BCDR_UTILS_IMAGE} ${TARGET_REGISTRY}/cpopen/cp4waiops/${BCDR_UTILS_IMAGE} \
   --from-dir "${IMAGE_PATH}" \
   -a ${REGISTRY_AUTH_FILE} \
   --filter-by-os '.*' \
   --insecure  \
   --skip-multiple-scopes \
   --max-per-registry=1
   ```

6. Create the **ImageContentSoucePolicy**.

   1. Switch to the namespace that IBM Cloud Pak for AIOpsis deployed in.

      ```
      oc project ${AIOPS_NAMESPACE}
      ```

   2. Run the following command to create the **ImageContentSourcePolicy**.

      ```
      cat << EOF | oc apply -f -
      apiVersion: operator.openshift.io/v1alpha1
      kind: ImageContentSourcePolicy
      metadata:
       name: bcdr-mirrors
      spec:
       repositoryDigestMirrors:
        - mirrors:
          - ${TARGET_REGISTRY}/cpopen/cp4waiops/
          source: icr.io/cpopen/cp4waiops/
      EOF
      ```

Troubleshooting

- Red Hat OpenShift APIs for Data Protection (OADP) installation failed
- Backups are not showing after installation

Red Hat OpenShift APIs for Data Protection (OADP) installation failed

If your installation of OADP fails for any reason, delete any related files and reattempt the installation.

For example, the installation script **install-oadp.sh** might not complete successfully. If this occurs an error similar to the following message can display:

```
error: unable to recognize "STDIN": no matches for kind "DataProtectionApplication" in version
"oadp.openshift.io/v1alpha1"
```

This can occur if the network or cluster is running slow and taking too long to pull the required images. This delay causes the OADP operator to take too long to create the required custom resource.

If the preceding issue occurs, or the installation fails for another reason, run the following **oc** commands to delete any existing OADP installation files before attempting to install again.

1. Delete any cluster service versions (CSV) in the project:

   ```
   oc delete csv --all -n ${OADP_NAMESPACE}
   ```

2. Delete any subscriptions in the project:

   ```
   oc delete subscription --all -n ${OADP_NAMESPACE}
   ```

3. Delete any deployments in the project:

   ```
   oc delete deploy --all -n ${OADP_NAMESPACE}
   ```

4. Delete any daemonsets in the project:

   ```
   oc delete ds --all -n ${OADP_NAMESPACE}
   ```

5. Delete the project (namespace):

   ```
   oc delete project ${OADP_NAMESPACE}
   ```

Any existing installation is deleted and you can reattempt the installation.

Backups are not showing after installation

If your backups do not show, complete the following steps:

1. Correct the **bucket** and **prefix** property within the **backupstoragelocation** resource that is named **bcdr-s3-location**. The **bucket** and **prefix** name should match the value that is defined within the **install-oadp-config.json** file during the OADP installation.

   Run the **oc edit** command to edit the **backupstoragelocation** resource:

   ```
   oc edit backupstoragelocation bcdr-s3-location -n ${OADP_NAMESPACE}
   ```

2. Delete the Velero pod by running the following command:

   ```
   oc delete pod <pod> -n ${OADP_NAMESPACE}
   ```

   The backups should now be available.

3. Run the following command to list the backups:

   ```
   velero get backup
   ```

Configuring ODF as backup storage for OADP

Learn how to create an object storage bucket in Red Hat OpenShift Data Foundation that Red Hat OpenShift APIs for Data Protection (OADP) can use to store backups in.

Overview

Use these instructions if you want to use Red Hat® OpenShift® Data Foundation as the backup storage for an OADP backup of IBM Cloud Pak® for AIOps. For more information about backing up IBM Cloud Pak for AIOps using OADP, see Installing the backup and restore tools.

Procedure

1. Create an S3-compatible object storage bucket
2. Retrieve the S3 bucket information and credentials
3. Prepare the DataProtectionApplication configuration
4. Verify that the backupStorageLocation object is created
5. Configure the volume snapshot classes for OADP

6. Back up a project to validate the OADP configuration

1. Create an S3-compatible object storage bucket

1. Create a YAML file called **obc-backup.yml** with the following content:

```
apiVersion: objectbucket.io/v1alpha1
kind: ObjectBucketClaim
metadata:
  name: backup
  namespace: openshift-adp
spec:
  storageClassName: openshift-storage.noobaa.io
  generateBucketName: backup
```

2. Run the following command to create an ObjectBucketClaim object called **backup** that uses the **openshift-storage.noobaa.io** storage class.

```
oc apply -f obc-backup.yml
```

2. Retrieve the S3 bucket information and credentials

When Red Hat OpenShift Data Foundation creates the **backup** ObjectBucketClaim instance, it also creates a secret and a configuration map named **backup**. The **backup** secret contains the bucket credentials, and the **backup** configuration map contains the bucket information.

1. Install **s3cmd**.

   s3cmd is a command-line tool and client for uploading, retrieving, and managing data in Amazon S3 and other cloud storage service providers.

   Install **s3cmd** from Amazon S3 Tools.

2. Retrieve the bucket name and bucket host from the **backup** configuration map.

```
oc extract --to=- cm/backup
```

   Example output:

```
# BUCKET_HOST
s3.openshift-storage.svc
# BUCKET_NAME
backup-7d9...f4c
# BUCKET_PORT
443
# BUCKET_REGION
# BUCKET_SUBREGION
```

3. Encode the certificate in Base64 format, and make a note of the returned value for use in step 3.1.

```
oc get cm/openshift-service-ca.crt -o jsonpath='{.data.service-ca\.crt}' | base64 -w0; echo
```

4. Retrieve the bucket credentials from the **backup** secret.

```
oc extract --to=- secret/backup
```

   Example output:

```
# AWS_ACCESS_KEY_ID
xxxxxKey_IDzzzzz
# AWS_SECRET_ACCESS_KEY
xxxxxxSecretxxxxx
```

5. Identify the public URL for the S3 endpoint from the s3 route in the **openshift-storage** namespace.

```
oc get route s3 -n openshift-storage
```

   Example output:

```
NAME   HOST/PORT                                                    PATH
SERVICES   PORT       TERMINATION       WILDCARD
s3     [s3-openshift-storage.apps.gocpprd1.emn.gdps.gov.sa] (https://s3-openshift-
storage.apps.gocpprd1.emn.gdps.gov.sa/)   s3         s3-https    reencrypt/Allow    None
```

6. Create a file called **.s3cfg** in your home directory with the S3 credentials and S3 endpoint URL.

```
access_key = <AWS_ACCESS_KEY_ID>
secret_key = <AWS_SECRET_ACCESS_KEY>
host_base = s3-openshift-storage.apps.gocpprd1.emn.gdps.gov.sa
host_base = <HOST_BASE>
host_bucket = <HOST_BASE>/%(bucket)s
signature_v2 = True
```

   Where

   - **<AWS_ACCESS_KEY_ID>** and **<AWS_SECRET_ACCESS_KEY>** are the values returned in step 2.4
   - **<HOST_BASE>** is the value returned in step 2.5. For example, **s3-openshift-storage.apps.gocpprd1.emn.gdps.gov.sa**

7. Validate the configuration

   Run the following command to list the contents of the bucket, and verify that the command returns no output because the bucket is empty. If the configuration is incorrect, then the command returns an error message.

   ```
   s3cmd la
   ```

3. Prepare the DataProtectionApplication configuration

1. Create a YAML file called **dpa-backup.yml**. Use the S3 bucket information from the previous steps to configure the default backup storage location.

   Example configuration:

   ```
   apiVersion: [oadp.openshift.io/v1alpha1](https://oadp.openshift.io/v1alpha1)
   kind: DataProtectionApplication
   metadata:
     name: oadp-backup
     namespace: openshift-adp
   spec:
     features:
       dataMover:
     configuration:
       velero:
         defaultPlugins:
           - aws
           - openshift
     backupLocations:
       - velero:
           config:
             profile: "default"
             region: "us-east-1"
             s3Url: https://s3.openshift-storage.svc/
             s3ForcePathStyle: "true"
             insecureSkipTLSVerify: "true"
           provider: aws
           default: true
           credential:
             key: cloud
             name:  cloud-credentials
           objectStorage:
             bucket: backup-6bce9ba8-59e1-4b2c-9c17-a88498954a56
             prefix: oadp
             caCert: <LS0tLS1.........>
   ```

2. Create the **cloud-credentials** secret in the **openshift-adp namespace** with the **backup** ObjectBucketClaim credentials.

   Create a file called **cloud-credentials** with the following content:

   ```
   [default]
   aws_access_key_id=<AWS_ACCESS_KEY_ID>
   aws_secret_access_key=<AWS_SECRET_ACCESS_KEY>
   ```

   Where **<AWS_ACCESS_KEY_ID>** and **<AWS_SECRET_ACCESS_KEY>** are the values retrieved in step 2.4.

   ```
   oc create secret generic cloud-credentials -n openshift-adp --from-file cloud=cloud-credentials
   ```

3. Create the **restic-enc-key** secret in the **openshift-adp** namespace, with an encryption key to use for application data.

   Run the following command, which uses openssl to generate a random password to use as the encryption key.

   ```
   oc create secret generic restic-enc-key -n openshift-adp --from-literal=RESTIC_PASSWORD=$(openssl rand -base64 24)
   ```

4. Run the following command to apply the OADP configuration.

   ```
   oc apply -f dpa-backup.yml
   ```

4 Verify that the backupStorageLocation object is created

Run the following command to verify that the backupStorageLocation object is created, and has a phase of **Available**.

```
oc get backupStorageLocation
```

Example output:

```
NAME           PHASE       LAST VALIDATED   AGE     DEFAULT
oadp-backup    Available   1s               3d16h   true
```

5. Configure the volume snapshot classes for OADP

1. Run the following command to list all the available volume snapshot classes.

   ```
   oc get volumesnapshotclass
   ```

2. Set the **deletionPolicy** attribute to *Retain* for each volume snapshot class.

   Run the following command:

   ```
   for class in \
   $(oc get volumesnapshotclass -oname); do
   oc patch $class --type=merge -p '{"deletionPolicy": "Retain"}'
   done
   ```

3. Set the **velero.io/csi-volumesnapshot-class** label to true for each volume snapshot class.

   Run the following command:

   ```
   oc label volumesnapshotclass velero.io/csi-volumesnapshot-class="true" --all
   ```

6. (Optional) Back up a project to validate the OADP configuration

Optionally test your configuration by backing up the resources in a test namespace. This example uses a test namespace called **production**.

1. Create a file called up **backup.yml** with the following content.

   ```
   apiVersion: velero.io/v1
   kind: Backup
   metadata:
     name: backup-production
     namespace: openshift-adp
   spec:
     includedNamespaces:
     - production
   ```

2. Run the following command to apply the backup configuration.

   ```
   oc apply -f backup.yml
   ```

3. Wait a couple of minutes and check the backup completion status. Verify that the backup object has a phase of *Completed*.

   ```
   oc describe backup backup-production
   ```

   Example output:

   ```
   Status:
     Completion Timestamp: 2024-05-22T13:52:25Z
     Expiration:           2024-06-21T13:51:33Z
     Format Version:       1.1.0
     Phase:                Completed
     Progress:
       Items Backed Up:  55
       Total Items:      55
   ```

4. Run the following command to review the contents of the S3 storage.

   ```
   s3cmd la -r
   ```

   Example output:

   ```
   $ s3cmd la -r
   2024-05-22 13:52   2597  s3://backup-6bce9ba8-59e1-4b2c-9c17-
   a88498954a56/docker/registry/v2/blobs/sha256/05/057c885bbca68570905d4a9e26948b6fa07e06ecc80951aa0def58cd227a2513/dat
   a
   2024-05-22 13:51   4512  s3://backup-6bce9ba8-59e1-4b2c-9c17-

Backing up IBM Cloud Pak for AIOps data

Learn how to back up data for IBM Cloud Pak for AIOps components.

The backup process uses Red Hat OpenShift APIs for Data Protection (OADP) for cluster object backups and volume backups. The backup script must be the same version as your deployment.

Note: If you also need to back up data for Infrastructure Automation components, the process and tools to use are the same. The only change that is required is when you are packaging the Helm chart. During this step you need to configure the value of the **enabledComponents** parameter to include **'"IA"'** as well as **'"AIOPS"'**. All other steps remain the same.

Prerequisites

- Ensure that you are logged in to your Red Hat OpenShift cluster with **oc login** for any steps that use the Red Hat OpenShift command-line interface (CLI).

- If they are not already installed, install the backup and restore tools. You need to install the Red Hat® OpenShift® Container Platform APIs for Data Protection (OADP) in the Red Hat OpenShift Container Platform cluster. For more information, see Installing the backup and restore tools.
- Provision S3 compliant object storage for your backups. You must have sufficient storage to backup the data that is contained in the datastores and persistent volume claims (PVCs) of the components that are backed up, as detailed in Backup process. The storage must also be accessible by any environment that a backup might need to be restored to. The backup process moves backup files to an S3 bucket, which must be in an S3 compatible location. For instance, you can use the following public or private cloud options for provisioning storage for your backups:
  - MinIO
  - Red Hat OpenShift Data Foundation object store
  - IBM Cloud Object Storage
  - AWS Cloud

  Important: Ensure that OADP is configured to point to the same object storage (S3 bucket) that includes the backup that you plan to use.

Note: As your data grows, the capacity of your backup storage might need to grow, and you must ensure that sufficient storage for backups is provisioned to accommodate any growth in backup data.

Backup procedure

Follow these steps to backup IBM Cloud Pak for AIOps.

1. Prepare to backup IBM Cloud Pak for AIOps
2. Backup IBM Cloud Pak for AIOps
3. Setup on-demand backups of IBM Cloud Pak for AIOps

1. Prepare to backup IBM Cloud Pak for AIOps

1. Clone the IBM Cloud Pak for AIOps samples GitHub repository to retrieve the latest IBM Cloud Pak for AIOps backup and restore scripts by running the following command:

   ```
   git clone https://github.com/IBM/cp4waiops-samples.git
   ```

   If you have an offline (air-gapped) deployment of IBM Cloud Pak for AIOps, then copy the cloned scripts to your air-gapped environment.

2. Export the environment variables that you will need for the backup procedure.

   If you are backing up an online deployment, set the following:

   ```
   export OADP_NAMESPACE=<oadpNamespace>
   export PATH=<path>
   export AIOPS_NAMESPACE=<aiops_namespace>
   ```

   If you are backing up an offline deployment, set the following:

   ```
   export TARGET_REGISTRY_HOST=<target_registry_host>
   export TARGET_REGISTRY_PORT=<port>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   export TARGET_REGISTRY_USER=<username>
   export TARGET_REGISTRY_PASSWORD=<password>
   export EMAIL=<email>
   export PATH=<path>
   export OADP_NAMESPACE=<oadpNamespace>
   export AIOPS_NAMESPACE=<aiops_namespace>
   ```

   Where:

   - `<target_registry_host>` is the IP address or FQDN of the target registry that holds the backup and restore images, from Offline deployments only: Mirror the backup and restore images
   - `<port>` is the port_number of the target registry
   - `<username>` is the username for the target registry
   - `<password>` is the password for the target registry
   - `<email>` is the email for the target registry
   - `<path>` is the path to where you downloaded and extracted the IBM Cloud Pak for AIOps backup and restore files.
   - `<oadpNamespace>` is the OADP namespace
   - `<aiops_namespace>` is the namespace where IBM Cloud Pak for AIOps is installed.

3. Package the Helm Chart.

   1. Change to the directory where you have the backup and recovery files downloaded.

      ```
      cd ${PATH}/bcdr/4.8.0/backup
      ```

   2. Set environment variables

      1. Run the following command to find the name of your IBM Cloud Pak for AIOps installation.

         ```
         oc get installation -n ${AIOPS_NAMESPACE}
         ```

         Example output, where `ibm-cp-aiops` is the name of the IBM Cloud Pak for AIOps installation:

         ```
         NAME          PHASE    LICENSE    STORAGECLASS  STORAGECLASSLARGEBLOCK  AGE
         ibm-cp-aiops  Running  Accepted   rook-cephfs   rook-ceph-rbd           34h
         ```

2. Run the following commands to find the name of your Elasticsearch backup PVC:

```
elasticsearch_cluster=$(oc get elasticsearchclusters.elasticsearch.opencontent.ibm.com -n
${AIOPS_NAMESPACE} -o jsonpath='{.items[0].metadata.name}')
esbackupPVC="$elasticsearch_cluster-ibm-elasticsearch-es-server-snap"
```

3. Update the following parameters in the **values.yaml** file. The file is located in the **./helm** directory.

   - **repository** - Do not edit this parameter.
   - **pullPolicy** - The policy for determining when to pull the image from the image registry server. For example, to force pull the image, use the **Always** policy.
   - **schedule** - (optional when on-demand backups are activated) The Cron expression for the automated backup. For example, to take a backup once a day, use the **0 0 * * *** Cron expression.
   - **backupStorageLocation** - The storage location where backed up data is stored. For example, **bcdr-s3-location**.

     Use the **oc get backupstoragelocation -n ${OADP_NAMESPACE}** command to get the **backupStorageLocation** on the OpenShift cluster.
   - **backupNameSuffix** - The prefix for the backup name when the backup is created by using the job. Generally, it can be name of source cluster itself. For example, **aiops-cluster-backup-106**.
   - **aiopsNamespace** - The namespace where IBM Cloud Pak for AIOps is installed.
   - **csNamespace** - The namespace where IBM Cloud Pak foundational services is installed. From IBM Cloud Pak for AIOps v4.4.0 this is the same as the namespace where IBM Cloud Pak for AIOps is installed.
   - **oadpNamespace** - The namespace where OADP is installed.
   - **redisBackupPod** - set this to *backup-data-<installation_name>-redis-server* where <installation_name> is the name that you found in the previous step.
   - **redisPVC** - set this to *data-<installation_name>-redis-server-* where <installation_name> is the name that you found in the previous step.
   - **redisSecret** - set this to *<installation_name>-redis-secret* where <installation_name> is the name that you found in the previous step.
   - **esBackupPVC**- set this to the value of **$esbackupPV** that you found in the previous step.
   - **ttl** - The time-to-live setting for the backup. The backed up data is retained until the **ttl** value is reached (expires). For example **720h0m0s**.
   - **enabledNamespaces** The namespaces of the components that need to be backed up. You can delete any unused namespaces from the list to reduce the time that is required for the backup process. If you have installed only IBM Cloud Pak for AIOps, then you require the namespaces that IBM Cloud Pak for AIOps and IBM Cloud Pak foundational services are installed in. From IBM Cloud Pak for AIOps v4.4.0, the IBM Cloud Pak foundational services namespace is the same as the IBM Cloud Pak for AIOps namespace, but this namespace must be listed twice, as in the following example.

     ```
     enabledNamespaces:
     - '"cp4aiops"'
     - '"cp4aiops"'
     ```
   - **enabledComponents** - Required. The list of components to back up.

     The backup and restore processes support backing up and restoring both the IBM Cloud Pak for AIOps and Infrastructure Automation components. These components can be installed together or independtly. You can specify to back up both, or only one of these components. Any other value is ignored and a corresponding error message is generated.

     To specify Infrastructure Automation, set the value **'"IA"'**.

     To specify IBM Cloud Pak for AIOps, set the value **'"AIOPS"'**.

     The following configuration shows both components listed:

     ```
     enabledComponents:
     - '"IA"'
     - '"AIOPS"'
     ```

4. Package the Helm Chart.

   ```
   helm package ./helm
   ```

4. Create a network policy.

   For more information about creating a **NetworkPolicy**, see Creating a network policy.

   1. Create a network policy file called **policy-bcdr.yaml** with the following contents:

      ```
      apiVersion: networking.k8s.io/v1
      kind: NetworkPolicy
      metadata:
       name: bcdr-np
       namespace: <aiopsNamespace>
      spec:
       podSelector:
        matchLabels:
          ibm-es-server: aiops-ibm-elasticsearch-es-server
       ingress:
      ```

```
  - from:
    - namespaceSelector:
        matchLabels:
          kubernetes.io/metadata.name: <oadpNamespace>
  policyTypes:
  - Ingress
```

Where:

- **<aiopsNamespace>** is the value of $AIOPS_NAMESPACE
- **<oadpNamespace>** is the value of $OADP_NAMESPACE

2. Apply the network policy to your cluster to allow the required ingress traffic.

```
oc apply -f policy-bcdr.yaml -n ${AIOPS_NAMESPACE}
```

2. Setup an automated backup of IBM Cloud Pak for AIOps

Run the following steps to trigger an automated backup.

1. Change to the **backup** directory where the script is located:

   ```
   cd ${PATH}/bcdr/4.8.0/backup
   ```

2. Deploy the backup job by running the following command:

   ```
   helm install backup-job clusterbackup-0.1.0.tgz
   ```

3. Optional - update the **schedule** parameter in the **values.yaml** file (located in the **./helm** directory). This uses a cron expression to schedule the automated backup. For example, to take a backup once a day, use the **0 0 * * *** Cron expression.

3. Setup on-demand backups of IBM Cloud Pak for AIOps

This step is optional. Use only when you do not want to wait untill the next scheduled backup job.

Prerequisite: The deployment of an automated backup job is a prerequisite for the on-demand job. Only after you initiate an automated backup job can you then trigger an on-demand backup.

1. Deploy the on-demand backup job by running the following command:

   ```
   oc create job --from=cronjob/backup-job on-demand-backup-job -n ${OADP_NAMESPACE}
   ```

2. Check the on-demand backup pods status by running the following command:

   ```
   oc get pods -n ${OADP_NAMESPACE}
   ```

3. Check the on-demand backup job logs by running the following command:

   ```
   oc logs -f <on-demand-backup-job-***> -n ${OADP_NAMESPACE}
   ```

4. Find and export the name of your backup.

   You can see the backup name after the on-demand backup job is complete. For example, you might see the backup name **aiops-cluster-backup-106-1622193915** in the on-demand backup job log as follows:

   ```
   Waiting for backup aiops-cluster-backup-106-1622193915 to complete
   ```

   Export the name of your backup by running the following command:

   ```
   export BACKUP_NAME=<backup_name>
   ```

   Where **<backup_name>** is the name of the backup.

5. Check the backup status by running the following command:

   ```
   velero get backup ${BACKUP_NAME} -n ${OADP_NAMESPACE}
   ```

   When the backup is finished, the status is **Completed**, such as in the following sample output:

   ```
   aiops-backup-1654171690-testfest34   Completed   2022-06-02 05:08:11 -0700 PDT   29d   bcdr-data-protection-app-1
   cp4aiops.ibm.com/backup=t
   ```

   To see more details, you can also:

   - Check the backup pods' status by running the following command:

     ```
     oc get pods -n ${OADP_NAMESPACE}
     ```

   - Check the backup job logs by running the following command:

     ```
     oc logs -f <backup-job-***>
     ```

6. Review the backup result summary that is included within the logs of the backup job.

   Note: A **backup-result-config** ConfigMap is created to include this result. To view this ConfigMap, run the following command:

```
oc get cm backup-result-config -n ${AIOPS_NAMESPACE} -o yaml
```

Troubleshooting

- Backup process is stuck in an *In progress* state
- Classifier and layout pods remain not ready after running a backup
- Helm install backup job command failed

Backup process is stuck in an *In progress* state

If your backup process remain stuck in an *In progress* state for an unexpected duration, complete the following steps. This procedure stops the backup process so that you can try the backup again.

1. Delete the Velero pod by running the following command:

   ```
   oc delete pod <pod> -n ${OADP_NAMESPACE}
   ```

2. Delete the backup that is stuck in the *In progress* state:

   ```
   velero delete backup <backup> -n ${OADP_NAMESPACE}
   ```

   Where **<backup>** is the backup that you want to delete. The backup process should begin again.

3. Wait for the process to complete and verify that the backup is created.

Classifier and layout pods remain not ready after running a backup

After you complete a backup, you might notice that the classifier (**aiops-ir-analytics-classifier**) and layout (**aiops-topology-layout**) pods do not change to a ready state, which can cause **AIOpsAnalyticsOrchestrator** to be stuck in an updating phase. This issue can occur after most backups. To resolve this issue, you need to either restart the pods or increase the resource limits for the pods.

- For the classifier (**aiops-ir-analytics-classifier**) pod, restart the pod.
- For the layout (**aiops-topology-layout**) pod, restart the pod. If the restart does not result in the pod becoming ready, increase the resource limits for the pod. Doubling the **cpu** and **memory** limits and request allocations for the pods can result in the pod starting and entering a ready state.

Helm install backup job command failed

When you are running the **helm install backup-job clusterbackup-0.1.0.tgz** command, you might encounter the command failing with an error that is similar to the following error:

```
Error: admission webhook "trust.hooks.securityenforcement.admission.cloud.ibm.com" denied the request:
Deny "icr.io/cpopen/cp4waiops/cp4aiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355", no
matching repositories in ClusterImagePolicy and no ImagePolicies in the "velero" namespace
```

If you encounter this error, complete the following steps to resolve the issue:

1. Uninstall the **backup-job** job by running the following command:

   ```
   helm uninstall backup-job -n ${OADP_NAMESPACE}
   ```

2. Export an environment variable for the image.

   For an online deployment:

   ```
   export REGISTRY=icr.io/cpopen/cp4waiops/cp4aiops-bcdr
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   For an offline deployment:

   ```
   export REGISTRY=$TARGET_REGISTRY
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   Where **<bcdr_image>** is the name of the backup and restore image, as given in the backup helm chart **values.yaml** file, in the form **cp4waiops-bcdr@{digest}**. An example value for BCDR_IMAGE is **icr.io/cpopen/cp4waiops/cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355**.

3. Create a **backup-image-policy.yaml** file and add the following content within the file:

   ```
   apiVersion: securityenforcement.admission.cloud.ibm.com/v1beta1
   kind: ClusterImagePolicy
   metadata:
     name: backup-image-policy
   spec:
    repositories:
     - name: ${BCDR_IMAGE}
       policy:
   ```

4. Apply the policy by running the following command:

   ```
   oc apply -f backup-image-policy.yaml
   ```

5. Deploy the backup job by running the following command:

   ```
   helm install backup-job clusterbackup-0.1.0.tgz
   ```

Restoring IBM Cloud Pak for AIOps data

Learn how to restore data for IBM Cloud Pak for AIOps components to a cluster, such as for disaster recovery.

The following procedure restores all backed up data that exists in the specified backup for IBM Cloud Pak for AIOps components. The steps in the following procedure restore IBM Cloud Pak for AIOps in a new cluster.

Before you begin

- All required storage classes must be created prior to running the restore process. The storage classes must have the same name as the backup cluster.
- You can restore a backup only within an environment that has the same version of IBM Cloud Pak for AIOps as the environment where the backup was created. For example, a backup of an IBM Cloud Pak for AIOps 4.8.0 environment must be restored within a cluster that has IBM Cloud Pak for AIOps 4.8.0 installed. If you need to upgrade as well as restore data, complete the restore process before you upgrade.
- If you are also restoring Infrastructure Automation data, the overall procedure is the same with the following additional steps required:
  - After you install IBM Cloud Pak for AIOps on the cluster where you are restoring data, you need to install Infrastructure Automation.
  - After you restore your IBM Cloud Pak for AIOps data, you need to restore your Infrastructure Automation data. For more information, see Restoring Infrastructure Automation.

Restore procedure

Follow the steps to restore IBM Cloud Pak for AIOps from backup.

1. Set up your new cluster for backup and restore
2. Prepare the backup data for restoring
3. Restore the cluster namespaces and install IBM Cloud Pak for AIOps
4. Restore the IBM Cloud Pak for AIOps data
5. (Optional) Restore Infrastructure Automation data
6. Post-restore tasks

If you encounter any issues with the restore process, see Troubleshooting

1. Set up your new cluster for backup and restore

1. Install Red Hat OpenShift by using the instructions in the Red Hat OpenShift documentation.

   IBM Cloud Pak for AIOps requires OpenShift to be installed and running. You must have administrative access to your OpenShift cluster.

   Important: Ensure that the version of Red Hat OpenShift Container Platform that you install is the same as the version that was installed in the backed up cluster.

   For information on supported versions of OpenShift, see Supported Red Hat OpenShift Container Platform versions.

   Note: IBM Cloud Pak for AIOps uses the OpenShift image registry when it builds images in real time. If the OpenShift image registry is not persistent and the registry respawns, then workloads can temporarily fail until respawning is complete. A persistent OpenShift image registry is recommended to avoid this. For more information, see Setting up and configuring the registry in the Red Hat OpenShift Container Platform documentation.

2. Install the OpenShift command line interface (`oc`) on your cluster's boot node and run `oc login`, using the instructions in Getting started with the OpenShift CLI.

3. Configure storage

   The storage configuration must satisfy your sizing requirements. For more information on the storage classes that are needed for installing IBM Cloud Pak for AIOps, see Storage.

   Important: All required storage classes must be created prior to running the restore process. The storage classes must have the same name as the backup cluster.

4. Install the backup and restore tools

   Install the Red Hat OpenShift APIs for Data Protection (OADP) in the Red Hat OpenShift Container Platform cluster. For more information, see Installing the backup and restore tools.

   Important: Ensure that the OpenShift APIs for Data Protection (OADP) is configured to point to the same object storage (S3 bucket) that includes the backup that you plan to use.

5. Export the environment variables that you will need for the restore procedure.

   If you are restoring to an online deployment, set the following:

   ```
   export PATH=<path>
   export OADP_NAMESPACE=<oadpNamespace>
   export AIOPS_NAMESPACE=<aiops_namespace>
   ```

   If you are restoring to an offline deployment, set the following:

   ```
   export TARGET_REGISTRY_HOST=<target_registry_host>
   export TARGET_REGISTRY_PORT=<port>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   ```

```
export TARGET_REGISTRY_USER=<username>
export TARGET_REGISTRY_PASSWORD=<password>
export EMAIL=<email>
export PATH=<path>
export OADP_NAMESPACE=<oadpNamespace>
export AIOPS_NAMESPACE=<aiops_namespace>
```

Where:

- **<target_registry_host>** is the IP address or FQDN of the target registry that holds the backup and restore images, from Offline deployments only: Mirror the backup and restore images
- **<port>** is the port_number of the target registry
- **<username>** is the username for the target registry
- **<password>** is the password for the target registry
- **<email>** is the email for the target registry
- **<path>** is the path to where you downloaded and extracted the IBM Cloud Pak for AIOps backup and restore files.
- **<oadpNamespace>** is the OADP namespace
- **<aiops_namespace>** is the namespace for the IBM Cloud Pak for AIOps deployment.

2. Prepare the backup data for restoring

Verify your backed up data and prepare the data for restoring.

1. Check the backup status

   Check the backup status to ensure that the backup that you want to restore in your cluster is complete. Run the following command to check the contents of the backup:

   ```
   velero describe backup <backup-name> --details
   ```

   The output should list the backed-up data for IBM Cloud Pak for AIOps (**cp4aiops/***) and for IBM Cloud Pak foundational services. If you also backed up Infrastructure Automation data, this data (**cp4aiops/***) should also be listed.

   The output should resemble the following sample output:

   ```
   v1/PersistentVolumeClaim:
     - cp4aiops/back-aiops-topology-cassandra-0
     - cp4aiops/data-c-example-couchdbcluster-m-0
     - cp4aiops/export-aimanager-ibm-minio-0
     - cp4aiops/aiops-ibm-elasticsearch-es-server-snap
     - cp4aiops/postgres-backup-data
     - cp4aiops/metastore-backup-data
   v1/Pod:
     - cp4aiops/backup-back-aiops-topology-cassandra-0
     - cp4aiops/backup-data-c-example-couchdbcluster-m-0
     - cp4aiops/backup-export-aimanager-ibm-minio-0
     - cp4aiops/backup-metastore
     - cp4aiops/es-backup
     - cp4aiops/backup-metastore
     - cp4aiops/dummy-db
   v1/Secret:
     - cp4aiops/aimanager-ibm-minio-access-secret
     - cp4aiops/aiops-ir-core-model-secret
     - cp4aiops/icp-serviceid-apikey-secret

   Velero-Native Snapshots: <none included>

   Restic Backups:
    Completed:
     cp4aiops/backup-back-aiops-topology-cassandra-0: backup
     cp4aiops/backup-data-c-example-couchdbcluster-m-0: backup
     cp4aiops/backup-export-aimanager-ibm-minio-0: backup
     cp4aiops/backup-metastore: data
     cp4aiops/es-backup: elasticsearch-backups
     cp4aiops/backup-postgres: backup
   ```

2. Package and install the Helm Chart

   1. Change to the **restore** directory where you need to package the Helm Chart:

      ```
      cd ${PATH}/bcdr/4.8.0/restore
      ```

   2. Update the following parameters in the **values.yaml** file. The file is located in the **./helm** directory:

      - **backupName** - The name of the backup that you are restoring.
      - **aiopsNamespace** - The namespace where IBM Cloud Pak for AIOps is installed.
      - **csNamespace** - The namespace where IBM Cloud Pak foundational services is installed. In IBM Cloud Pak for AIOps v4.8.0 this is the same as the namespace where IBM Cloud Pak for AIOps is installed.
      - **oadpNamespace** - The namespace where OADP is installed.

   3. Package the Helm Chart.

      ```
      helm package ./helm
      ```

   4. Install the Helm Chart for restoring data by running the following job:

      ```
      helm install restore-job clusterrestore-0.1.0.tgz
      ```

3. Restore the cluster namespaces and install IBM Cloud Pak for AIOps

Since the restore job does not install IBM Cloud Pak for AIOps, you need to first install IBM Cloud Pak for AIOps before you can run the restore jobs for restoring database and component data. A restore job for restoring the cluster namespaces is available and must be run before you install IBM Cloud Pak for AIOps.

1. Restore the cluster namespaces

   You need to restore the projects (namespaces) of the backed up cluster so that your new cluster includes the metadata with the SELinux settings that need to match the settings for the backup data that you plan to restore.

   These steps only restore the namespaces and namespace metadata. The commands do not restore the contents of the namespaces.

   Note: In IBM Cloud Pak for AIOps v4.8.0, the IBM Cloud Pak foundational services namespace is the same as the IBM Cloud Pak for AIOps namespace.

   1. Change to the **restore** directory where the restore script is located:

      ```
      cd ${PATH}/bcdr/4.8.0/restore
      ```

   2. Optional. Delete any existing namespace restore jobs:

      ```
      oc delete -f ns-restore-job.yaml
      ```

   3. Create a job to restore the cluster namespaces:

      ```
      oc create -f ns-restore-job.yaml
      ```

   4. Check the restore job logs by running the following command:

      ```
      oc logs -f <ns-restore-job-***>
      ```

   5. Check the velero-restore status for the namespace by running the following command:

      ```
      velero get restore <RESTORE_NAME>
      ```

      Where **<RESTORE_NAME>** is the name of the restore for namespace. You can see the restore name after the restore job is completed. For example, you might see the restore name **aiops-namespace-restore-20221006054710** within the restore job log as follows:

      ```
      Restore request "aiops-namespace-restore-20221006054710" submitted successfully.
      ```

      Ensure that the projects (namespaces) are restored before you proceed.

2. Create a network policy.

   For more information about creating a **NetworkPolicy**, see Creating a network policy.

   1. Create a network policy file called **policy-bcdr.yaml** with the following contents:

      ```
      apiVersion: networking.k8s.io/v1
      kind: NetworkPolicy
      metadata:
       name: bcdr-np
       namespace: <aiopsNamespace>
      spec:
       podSelector:
        matchLabels:
          ibm-es-server: aiops-ibm-elasticsearch-es-server
       ingress:
       - from:
         - namespaceSelector:
             matchLabels:
               kubernetes.io/metadata.name: <oadpNamespace>
       policyTypes:
       - Ingress
      ```

      Where:

      - **<aiopsNamespace>** is the value of $AIOPS_NAMESPACE
      - **<oadpNamespace>** is the value of $OADP_NAMESPACE

   2. Apply the network policy to your cluster to allow the required ingress traffic.

      ```
      oc apply -f policy-bcdr.yaml -n ${AIOPS_NAMESPACE}
      ```

3. Install IBM Cloud Pak for AIOps

   For more information, see Installing IBM Cloud Pak for AIOps.

   Important:

   - Ensure that the version of IBM Cloud Pak for AIOps that you are installing is the same as the version that was installed in the backed up cluster.
   - The backup includes keys and certificates from the backed up cluster. Ensure that your new cluster is configured to support the use of these keys and certificates so that the restored data can be accessed.
   - Wait until the installation is complete and all pods in the IBM Cloud Pak for AIOps project (namespace) are running before you proceed.

4. Optional. If you also need to restore Infrastructure Automation data, you need to install the Infrastructure Automation operators and create the required custom resources.

   - For more information about installing Infrastructure Automation, see Installing Infrastructure Automation.

- For more information about restoring Infrastructure Automation, see Restoring Infrastructure Automation.

4. Restore the IBM Cloud Pak for AIOps data

This procedure restore the data for all backed up IBM Cloud Pak for AIOps databases and components. Optionally, you can choose to restore only individual components. For details, see Restoring individual components.

1. Change to the **restore** directory where the restore script is located:

   ```
   cd ${PATH}/bcdr/4.8.0/restore
   ```

2. Optional. Delete any existing IBM Cloud Pak for AIOps restore jobs:

   ```
   oc delete -f aiops-restore-job.yaml
   ```

3. Create a job to restore IBM Cloud Pak for AIOps:

   ```
   oc create -f aiops-restore-job.yaml
   ```

4. Check the restore job logs by running the following command:

   ```
   oc logs -f <aiops-restore-job-***>
   ```

5. Check the velero-restore status by running the following command:

   ```
   velero get restore <RESTORE_NAME>
   ```

   Where **<RESTORE_NAME>** is the name of the restore for IBM Cloud Pak for AIOps. You can see the this restore name after the restore job is completed. For example, you might see the restore name **cassandra-restore-20221006054710** for the Cassandra restore in the restore job log as follows:

   ```
   Restore request "cassandra-restore-20221006054710" submitted successfully.
   ```

   Similarly, the OADP restore name for other IBM Cloud Pak for AIOps components can display in the restore job log.

   Note: You might notice that the **aiops-configmaps** resource group shows as failed under the **Restore sequence** section of the IBM Cloud Pak for AIOps restore recipe but the overall restore is successful and works as intended.

5. (Optional) Restore the Infrastructure Automation data

If you are also restoring Infrastructure Automation data, run the commands to restore the Infrastructure Automation data. For more information, see Restoring Infrastructure Automation.

6. Post-restore tasks

1. Update your integrations.

   If you have an integration that you are restoring, the status for these integrations can be in error after the restore process completes. To resolve this status, you need to edit and save your integrations with the Integrations feature in the IBM Cloud Pak for AIOps console. Editing the integration regenerates the associated Flink job for the integration, which updates the status. For more information about editing these integrations, see Defining integrations. Sometimes an integration can fail to gather data but not show an error status. To resolve this, edit and save the integration.

2. If you are restoring data for any integrations that are remotely deployed, complete the following steps to redeploy the integrations:

   1. On the remote cluster, delete any existing integrations.
   2. For each remotely deployed integration that you need to redeploy, Copy or download a new bootstrap command for the deployment script from cluster where the restore process ran.

      You can click the **Copy to clipboard** button to copy the command, or click **Download as a sh-file** to download the command as a **bootstrap.sh** file.

      Note: If you do not obtain the command now, you can copy or download the command later by completing the following steps:

      1. Log in to IBM Cloud Pak for AIOps console.
      2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
      3. For each integration, click the integration type on the *Manage integrations* tab of the Integrations page.
      4. On the page for the integration type, click the **Download** link in the **Remote deployment script** column for the integrations.
      5. Either copy or download the bootstrap command for the deployment script.

   3. Run the remote deployment scripts on the remote cluster to redeploy the integrations.

      1. Get the OpenShift CLI **oc login** command from the remote cluster.
      2. From a command line, log in to the remote cluster with the **oc login** command.
      3. Switch to the target project (namespace).
      4. Run the deployment script as a **sh** (script file), such as the downloadable **bootstap.sh** file.

3. If you are resoring secure tunnels data, install the secure tunnel connections for any restored secure tunnel data.

1. Optional. If the tunnel exists on your cluster, uninstall the existing tunnel connection.
2. Install the Secure Tunnel connector on your restored cluster.
3. Create the secure tunnel connection on your restored cluster.

4. Enable authentication with the restored JWT certificate.
   1. Retrieve the new **initial_admin_password** from the **admin-user-details** secret.

      ```
      export PROJECT=<project>
      PASS=$(oc get secret admin-user-details -n ${PROJECT} -o jsonpath='{.data.initial_admin_password}' | base64 -d)
      ```

   2. Disable the **admin** user.

      ```
      oc rsh -n ${PROJECT} $(oc get pod -l component=usermgmt -n ${PROJECT} | tail -1 | cut -f1 -d\ )
      /usr/src/server-src/scripts/manage-user.sh --disable-user admin
      ```

   3. Enable the **admin** user with the new password.

      ```
      echo "$PASS" | oc rsh -n ${PROJECT} $(oc get pod -l component=usermgmt -n ${PROJECT} | tail -1 | cut -f1 -d\ )
      /usr/src/server-src/scripts/manage-user.sh --enable-user admin
      ```

   4. Delete the secret **app-api-user-jwt**. It will be recreated automatically after a few seconds.

      ```
      oc delete secret app-api-user-jwt -n ${PROJECT}
      ```

Restoring individual components

If needed, you can choose to restore data for specific individual databases and components instead of for all databases and components at once.

1. Change to the **restore** directory where the restore script is located:

   ```
   cd ${PATH}/bcdr/4.8.0/restore
   ```

2. Copy the **aiops-restore-job.yaml** file. Rename your new file **<component>-restore-job.yaml**, where **<component>** is the name of the component that you are restoring.

   For example, if you are restoring Cassandra, rename the file to be **cassandra-restore-job.yaml**.

3. Open the new **<component>-restore-job.yaml** file for editing. Update the **name** and **command** sections to match the values for the component that you are restoring:

   - Update the **name** of the restore job in the metadata section to be the individual component job, such as **cassandra-restore-job**.
   - Update the command section **command: ["/bin/bash", "restore.sh","-aiops"]** to replace **-aiops** with the respective argument for the component that you are restoring. For the list of component arguments, see the table that follows this procedure.

4. Create a job to restore the individual component.

   ```
   oc create -f <component>-restore-job.yaml
   ```

5. Check the restore job logs by running the following command:

   ```
   oc logs -f <cp4waiops-component-restore-job-***>
   ```

6. Check the velero-restore status by running the following command:

   ```
   velero get restore <RESTORE_NAME>
   ```

   Where **<RESTORE_NAME>** is one of the restore names for the component. You can view the names for the component in the restore job log when the restore job is completed. For example, the restore name for a Cassandra restore can be **cassandra-restore-20221006054710**, which can display in an entry similar to the following example log entry:

   ```
   Restore request "cassandra-restore-20221006054710" submitted successfully.
   ```

Component or database arguments for restore job command configuration

Table. Component or database arguments for restore job commands

Component or Database	Argument
Cassandra	**-cassandra**
CouchDB	**-couchdb**
Elasticsearch	**-es**
Metastore	**-metastore**
Minio	**-minio**
Postgres	**-postgres**
IBM Cloud Pak foundational services	**-cs**
Intergration CR	**-connectioncr**
Secure Tunnel CR	**-tunnelcr**

Troubleshooting

- Stale alert data exists after restoration
- Restore process for ElasticSearch failed
- Restore fails with CouchDB pod in CrashLoopBackOff
- LDAP user login is not working after a restore
- Data is not being processed after restoration
- Applications still show non-existent active incidents and alerts notations
- Topology observer jobs do not run after restore
- Restore process terminated mid-process with partial data available
- OADP restore is stuck in an In progress state
- Helm install restore job command failed
- Cassandra restore fails with `org.apache.cassandra.io.FSReadError` exception
- Integrations missing after a restore
- Netcool integration is missing details after restore
- Restore fails with lifecycletrigger: Not Ready
- Cannot login to the Cloud Pak for AIOps console
- Policy configuration is not retained on the restored deployment
- Troubleshooting the Infrastructure Automation restore

Stale alert data exists for topology resources after restoration

After you complete a restore, you might notice notice that stale alert data exists for topology resources. For instance, if you search for a resource that had alert data, you might see outdated alert data. To clear the historical alert data, you can run the **`statusClear`** crawler.

You can run the crawler to clear stale events by using the topology service Swagger pages:

1. Open the Swagger API for the topology service. For more information, see Accessing Topology service Swagger UI.
2. Go to the Crawlers section.
3. Open the statusClear crawler.
4. Run the crawler with the default message body.

This crawler runs asynchronously over the topology data. The crawler POST response returns an EntityId header, which you can use to check the progress of the crawler. To check the progress include the EntityId header in a **`GET /mgmt_artifacts/{id}`** call. The response shows the status of the asynchronous crawl.

For more information about the topology service Swagger, see Application and topology APIs.

Restore process for ElasticSearch failed

If the restore of a particular data store, such as ElasticSearch, or custom resource fails, complete the following steps before you can attempt the restore again.

1. Optional. If this cluster was previously configured to enable a backup of ElasticSearch, or you need to rerun restore, complete the following steps:

    1. Remove the backup path and Snapshot location configurations from the AutomationBase CR.

    2. Delete the ElasticSearch backup snapshot PVC by running the following command. This deletion is needed since this PCV is replaced with the ElasticSearch backup data and the **`es-restore1`**.

        ```
        elasticsearch_cluster=$(kubectl get elasticsearchclusters.elasticsearch.opencontent.ibm.com -n
        ${AIOPS_NAMESPACE} -o jsonpath='{.items[0].metadata.name}')
        esbackupPVC="$elasticsearch_cluster-ibm-elasticsearch-es-server-snap"

        oc delete pvc -n ${AIOPS_NAMESPACE} $esbackupPVC
        ```

    3. Run the following command to delete the snapshot and **`es-restore1`** if it exists:

        ```
        oc delete restore es-restore1 -n $OADP_NAMESPACE
        ```

2. Repeat the process to restore the data store or custom resource to reattempt the failed restore.

Restore fails with CouchDB pod in CrashLoopBackOff

This problem can occur if you restore an IBM Cloud Pak for AIOps backup to a different cluster or namespace and the database files in the persistent storage are not readable or writeable by the root user group.

When this issue occurs, the pod **`c-example-couchdbcluster-m`** has a status of *CrashLoopBackOff*, as in the following example.

```
oc get pods | grep couchdb
c-example-couchdbcluster-m-0                                      1/2     CrashLoopBackOff        533 (4m13s ago)   2d5h
c-example-couchdbcluster-m-0-debug                                1/2     Running                 0                 2m39s
```

The logs from the database container in the failing pods contain the message **`Could not open file /data/db/_nodes.couch: permission denied`**, as in the following example:

```
oc logs c-example-couchdbcluster-m-0 -c db --tail=100
[error] 2022-11-10T10:39:34.788855Z couchdb@c-example-couchdbcluster-m-0.c-example-couchdbcluster-m <0.322.0> --------
Could not open file /data/db/_nodes.couch: permission denied
```

To resolve this issue, grant the root group write permissions to the folders in the persistent storage that contain the database files.

1. Get the name of the persistent volume that contains the CouchDB database files.

    ```
    oc get pv | grep couch
    ```

    Example output:

```
oc get pv | grep couch
pvc-d6599cfb-aa38-47be-857e-a2efa9ee0407   5Gi        RWO            Delete           Bound    katamari/data-c-
example-couchdbcluster-m-0                              rook-cephfs              2d5h
```

2. Find the worker node for the failing CouchDB pod.

```
oc get pod -o wide c-example-couchdbcluster-m-0
```

Example output:

```
oc get pod -o wide c-example-couchdbcluster-m-0
NAME                           READY   STATUS             RESTARTS         AGE    IP              NODE
NOMINATED NODE   READINESS GATES
c-example-couchdbcluster-m-0   1/2     CrashLoopBackOff   537 (76s ago)   2d5h   10.254.15.54   worker1.bcdr-test-
12345678.mysite.com   <none>           <none>
```

3. Debug the worker node that you identified in the previous step.

```
oc debug node/<worker_node>
```

Where **<worker_node>** is the value returned for *NODE* in the previous step.

Example output:

```
oc debug node/worker1.bcdr-test-12345678.mysite.com
Starting pod/worker1bcdr-rtp-26101516cpmyclustercom-debug ...
To use host binaries, run `chroot /host`
Pod IP: 10.22.1.1
If you don't see a command prompt, try pressing enter.
```

4. Find the mount point of the persistent volume.

```
mount | grep <pv>
```

Where **<pv>** is the persistent volume name returned in step 1.

Example output:

```
sh-4.4# mount | grep pvc-d6599cfb-aa38-47be-857e-a2efa9ee0407
172.30.2.127:6789,172.30.43.40:6789,172.30.11.17:6789:/volumes/csi/csi-vol-0bb3b8e3-5f26-11ed-97a6-
0a580afe2807/af21d8e8-f29e-4111-8fcd-c4366d604c99 on /host/var/lib/kubelet/plugins/kubernetes.io/csi/pv/pvc-
d6599cfb-aa38-47be-857e-a2efa9ee0407/globalmount type ceph (rw,relatime,seclabel,name=csi-cephfs-node,secret=
<hidden>,acl,mds_namespace=rook-cephfilesystem)
172.30.2.127:6789,172.30.43.40:6789,172.30.11.17:6789:/volumes/csi/csi-vol-0bb3b8e3-5f26-11ed-97a6-
0a580afe2807/af21d8e8-f29e-4111-8fcd-c4366d604c99 on /host/var/lib/kubelet/pods/26fc2b39-aaf0-4add-8649-
6cfd56fc4a3b/volumes/kubernetes.io~csi/pvc-d6599cfb-aa38-47be-857e-a2efa9ee0407/mount type ceph
(rw,relatime,seclabel,name=csi-cephfs-node,secret=<hidden>,acl,mds_namespace=rook-cephfilesystem)
```

The mount point is the directory ending with **mount**. In the above example output this is **/host/var/lib/kubelet/pods/26fc2b39-aaf0-4add-8649-6cfd56fc4a3b/volumes/kubernetes.io~csi/pvc-d6599cfb-aa38-47be-857e-a2efa9ee0407/mount**

5. Change the permissions on the mount directory by changing to the directory and running **chmod**.

```
cd <mount_dir>
chmod -R g+w
ls -lah db/
exit
```

Where **<mount_dir>** is the directory you identified in the previous step.

Example output:

```
sh-4.4# cd /host/var/lib/kubelet/pods/26fc2b39-aaf0-4add-8649-6cfd56fc4a3b/volumes/kubernetes.io~csi/pvc-d6599cfb-
aa38-47be-857e-a2efa9ee0407/mount
sh-4.4# ls
db  view_index
sh-4.4# ls -lah db/
total 37K
drwxr-xr-x. 4 1000650000 root    4 Nov  7 04:55 .
drwxrwxrwx. 5 root       root    3 Nov 10 10:52 ..
drwxr-xr-x. 2 1000650000 root    0 Nov  7 04:54 .delete
-rw-r--r--. 1 1000650000 root  29K Nov  7 05:31 _dbs.couch
-rw-r--r--. 1 1000650000 root 8.3K Nov  7 04:54 _nodes.couch
drwxr-xr-x. 4 1000650000 root    2 Nov  7 04:55 shards
sh-4.4# chmod -R g+w .
sh-4.4# ls -lah db/
total 37K
drwxrwxr-x. 4 1000650000 root    4 Nov  7 04:55 .
drwxrwxrwx. 5 root       root    3 Nov 10 10:52 ..
drwxrwxr-x. 2 1000650000 root    0 Nov  7 04:54 .delete
-rw-rw-r--. 1 1000650000 root  29K Nov  7 05:31 _dbs.couch
-rw-rw-r--. 1 1000650000 root 8.3K Nov  7 04:54 _nodes.couch
drwxrwxr-x. 4 1000650000 root    2 Nov  7 04:55 shards
sh-4.4# exit
```

6. Run the following command to verify that the CouchDB pod has a status of **Running**.

```
oc get pods | grep couchdb
```

Example output:

```
c-example-couchdbcluster-m-0                                  2/2     Running                 539 (87s ago)
2d5h
```

LDAP user login is not working after a restore

Follow the steps to solve the problem:

1. Log in to the console as the default admin user.
2. From the main navigation menu, click **Administer** > **Identify and access**.
3. Select the LDAP connection, and click **Edit connection**. Edit the LDAP connection with the correct information.
4. Click **Test connection**.
5. Click **Save** once the connection is success.
6. log in to the console with the LDAP user's credentials.

Data is not being processed after restoration

After you complete a restore, you might notice that data for some AI modeling features, such as log anomaly detection, change risk, similar tickets, might not be processed.

This can occur when expected Kafka topics for the AI modeling is not present after the restore completes. To resolve this problem, restart the **`aimanager-aio-controller`** pod. This restart can result in the creation of the expected Kafka topics.

Applications still show non-existent active incidents and alerts notations

After you complete a restore, you might notice notice that active incidents and alerts notations display for applications when the incidents and notations no longer exist. When the topology data store is backed up and restored, it contains restored data which is out of sync with the rest of the system due to the way the data is modelled against groups, applications, and resources within the topology.

If your data is outdated, you need to manually delete the topology association between the incidents and applications. Use the topology API to clear out any groups or events. Once removed, the changes are incorporated into the topology view.

To remove groups (incident groups of entity **`waiopsStory`**) use the API:

- **`GET /topology/groups?_type=waiopsStory`**
- **`DELETE /topology/groups?_type=waiopsStory`**

To remove events, remove the incorrect status from the topology with the following API:

- **`GET /topology/status`**
- **`DELETE /topology/status`**

Alternatively, you can use the *Resource management* tool in the UI to remove non-existant alert indiciations from a topology. When you are viewing a topology in the UI, open the **Settings** menu and select **Topology configuration**. From the**Data administration routines** page, run the **Status clear** routine to remove the alert indications.

Topology observer jobs do not run after restore

After running the restore procedure, some observer jobs are offline, have a **Status** of **`Error`**, or have a **Status** of **`Running`** even though job runs are being skipped.

For jobs with a job type of **`Repeating Schedule`**, this problem can occur when a restore ran from a backup that was taken while the observer job was waiting for data processing to finish. After the restore completes, the observer then starts with the job still in a FINISHING state. The observer waits for its job to finish, but the job cannot finish because the referenced data was not backed up, and so the job becomes stuck. Messages similar to the following might be seen in the observer log:

```
execution skipped because current job  had state: FINISHING
```

For other jobs that do not have a job type of **`Repeating Schedule`**, the observer log shows that it is looking for a vertex that no longer exists:

```
WARN   [2022-09-13 16:06:24,265] [pool-5-thread-1] c.i.i.t.o.t.ObserverVertex -  Failed to poll observer vertex
cp4waiops-cartridge.github-observer.  Response : InboundJaxrsResponse{context=ClientResponse{method=POST,
uri=https://aiops-topology-topology:8080/1.0/topology/mgmt_artifacts/MKSrcRpkRC6WmWVGGdSukA, status=404, reason=Not
Found}}
```

To resolve these problems, complete the following steps:

1. Locate jobs that are stuck in the **`FINISHING`** state.

   For jobs with a **Job type** of **`Repeating schedule`**, check if the job is stuck by waiting for the normal job duration or by checking the job history. If the job has been stuck for a long time, subsequent runs will be skipped. Use the following steps to navigate to the Observer configuration user interface (UI), view the observer job history and look for job runs that have been continuously skipped since the restore completed.

   1. Log in to IBM Cloud Pak for AIOps console.
   2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
   3. On the *Integrations* page, click **Add integration**.
   4. On the *Add integrations** page, click **Topology** in the *Category* list that is next to the list of all integrations.
   5. Click the **configure, schedule, and manage other observer jobs** link in the description for the topology integrations.
   6. Click the three dots icon at the end of the line for the observer job, and select **View history**.
   7. Click **All**, and look for runs with **`Skipped`** status and a **Details** entry of **`execution skipped because current job had state: FINISHING`**.

   For more information on viewing observer jobs, see the section **`To access the Observer Configuration UI`** in Defining observer jobs for application and topology data.

2. Attempt to restart the observer job.

1. For each observer job with a **Job type** of `Repeating schedule` that you identified in FINISHING state, edit the job in the Observer configuration UI by nominally changing the **Optional description** field, and saving it.

2. For other observer jobs that do not have a **Job type** of `Repeating schedule` and have a missing vertex issue, delete the related observer pod.

   ```
   oc delete pod <pod_name> -n <namespace>
   ```

   Where

   - `<pod_name>` is the observer pod to be deleted.
   - `<namespace>` is the project (namespace) where IBM Cloud Pak for AIOps is installed.

   For example, for an Instana observer job that has a missing vertex issue, delete the Instana observer pod:

   ```
   oc get pods -n | grep instana
   aiopsedge-instana-topology-integrator-6b777bd6b4-6nvqx 1/1 Running 0 8d

   oc delete pod aiopsedge-instana-topology-integrator-6b777bd6b4-6nvqx -n <cp4aiops-namespace>
   ```

   This causes the job to stop and restart, and to be shown as **Running**, **Scheduled**, or **Ready**.

   A message similar to the following is seen in the observer log:

   ```
   WARN   [2022-08-22 16:19:34,706] [pool-10-thread-1] c.i.i.t.o.a.JobManager -  stop - Stopped job for
   tenantId:cfd95b7e-3bc7-4006-a4a8-a73a79c71255, uniqueId:1100
   INFO   [2022-08-22 16:19:34,712] [cfd95b7e-3bc7-4006-a4a8-a73a79c71255:1100] c.i.i.t.o.f.j.LoadFileJob -
   cfd95b7e-3bc7-4006-a4a8-a73a79c71255:5eb27ee0-772c-4d65-bc0f-4e56b6b7913b Interrupted while waiting for state
   JobState [state=FINISHED, reason=Job finished after restart, date=Mon Aug 22 16:09:45 GMT 2022]
   INFO   [2022-08-22 16:19:34,944] [cfd95b7e-3bc7-4006-a4a8-a73a79c71255:1100] c.i.i.t.o.f.j.LoadFileJob -
   cfd95b7e-3bc7-4006-a4a8-a73a79c71255:1100 Observer job finished with state STOPPED
   ```

   Some jobs might still be shown with `Error` if an attempt was made to run the stuck job before the previous remediating steps were attempted. This causes the observer to fail the job, as a job already exists with the same name. In this scenario, a warning similar to the following is seen in the observer log:

   ```
   WARN   [2022-08-23 15:58:50,431] [pool-10-thread-1] c.i.i.t.o.a.o.RESTApiException -  pool-10-thread-1 - APIMessage:
   { httpCode=422, _error={ message=Job Creation Failure, level=warning, description=Cannot create observation job,
   causes=[{ message=Duplicate unique id, level=error, description=A job with the same unique id '1100' is already
   being processed., field=unique_id }] } }
   ```

   If there are no longer any observer jobs with a **Status** of `Error`, then exit this troubleshooting.

3. Complete the following steps only if one or more of your observer jobs are still shown with a **Status** of `Error`.

   1. Find the name of the topology pod.

      ```
      oc get pods | grep topology-topology
      ```

   2. Remote shell into the topology container.

      ```
      oc rsh <topology_pod> -c <release_name>-topology-topology
      ```

      Where

      - `<topology_pod>` is the pod that was returned in the previous step.
      - `<release_name>` is the name of your IBM Cloud Pak for AIOps instance.

4. Find observers that still have a job that is stuck in the `FINISHING` state.

   Run the following command, and note down the returned `observerName` and `_id`.

   ```
   curl -X GET "https://localhost:8080/1.0/topology/mgmt_artifacts?
   _filter=hasState%3DFINISHING&_field=keyIndexName&_field=hasState&_field=observerName&_type=ASM_OBSERVER_JOB" -H
   "accept: application/json" -H  "X-TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255" --insecure -u
   ${ASM_USER}:${ASM_PASS} | jq
   ```

   Note: ASM_USER and ASM_PASS are environment variables available within the topology container.

   Example output:

   ```
   {
    "_executionTime": 13,
    "_offset": 0,
    "_limit": 50,
    "_items": [
      {
        "keyIndexName": "dns-observer:bbc",
        "_id": "z7ovGeNrSKSpMlWY8n7Mfw",
        "observerName": "dns-observer",
        "hasState": "FINISHING"
      }
    ]
   }
   ```

5. Run the following steps for each observer job returned by the previous step.

   1. Change the state of the job by running the following command.

      ```
      curl -X POST "https://localhost:8080/1.0/topology/mgmt_artifacts/<id>" -H  "accept: application/json" -H  "X-
      TenantID: cfd95b7e-3bc7-4006-a4a8-a73a79c71255" -H  "Content-Type: application/json" -d "{  \"hasState\":
      \"FINISHED\"}" --insecure -u ${ASM_USER}:${ASM_PASS}
      ```

      Where `<id>` is the `_id` of the stuck job that you identified in step 4.

2. Find the pods for the observer that you need to restart.

   ```
   oc get pods -n <namespace> | grep <stuck_observer_name>
   ```

   Where

   - **<stuck_observer_name>** is the name of the stuck observer that you identified in step 4.
   - **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.
3. Delete the pods for the observer.

   ```
   oc delete po <observername_pods> -n <namespace>
   ```

   Where

   - **<observername_pods>** are the pods returned in the previous step.
   - **<namespace>** is the project (namespace) where IBM Cloud Pak for AIOps is installed.
4. Rerun the observer job.

   On the observer configuration UI, click **Run** on any job for the observer that is in the **Error** state. The observer job now runs successfully, and has a status of **Scheduled** or **Ready**.

Restore process terminated mid-process with partial data available

If the restore process does not complete as expected for a data store, such as if it is aborted or terminated during its run, data might not be restored correctly. This incomplete restored data neeeds to be removed before you run the restore process again. To remove the data, you need to run a post-restore cleanup script to clean up the data store.

To run a script, complete the following steps:

1. Define the following environment variable on your workstation:

   ```
   export WORKDIR="${PATH}/bcdr/4.8.0/"
   ```

2. Change to the **restore** directory where the post-restore cleanup script is located:

   ```
   cd <Path>/bcdr/4.8.0/restore/<data_store>/
   ```

   Where

   - **<Path>** is the path to where you downloaded and extracted the IBM Cloud Pak® for AIOps backup and restore files.
   - **<data_store>** is the directory for the data store or custom resource that needs to be cleaned up. For example, **couchdb** is the directory for CouchDb.
3. Run the post-restore cleanup script:

   ```
   nohup ./<data-store>-post-restore.sh.sh > <data-store>-post-restore.log &
   ```

   Where **<data_store>** is the data store or custom resource that needs to be cleaned up.

4. Run the restore process for that data store or resource again.

For example, if the restore job for restoring the Cassandra data store aborted, you need to run the **cassandra-post-restore.sh** post-restore script that is stored in the **bcdr/restore/cassandra** directory to clean the data. Then, run the **cassandra-native-post-restore.sh** post-restore script.

The following table lists the cleanup script to run for each data store:

Table. Cleanup script for components

Component or Database	Cleanup script
Cassandra	Run first: **bcdr/4.8.0/restore/cassandra/cassandra-post-restore.sh** Then, run: **bcdr/4.8.0/restore/cassandra/cassandra-native-post-restore.sh**
CouchDB	**bcdr/4.8.0/restore/couchdb/couchdb-post-restore.sh**
Elasticsearch	**bcdr/4.8.0/restore/elasticsearch/es-post-restore.sh**
Metastore	**bcdr/4.8.0/restore/metastore/metastore-post-restore.sh**
Minio	**bcdr/4.8.0/restore/minio/minio-post-restore.sh**
Postgres	**bcdr/4.8.0/restore/postgres/postgres-post-restore.sh**
IBM Cloud Pak foundational services	**bcdr/4.8.0/restore/common-services/cs-post-restore.sh**
Connection CR	N/A
Secure Tunnel CR	**bcdr/4.8.0/restore/other-resources/tunnel-cr-post-restore.sh**

OADP restore is stuck in an `In progress` state

If you notice that the Velero pod is stuck in an **In progress** state, complete the following steps to stop the restore process:

1. Delete the velero pod by running the following command:

   ```
   oc delete pod <velero pod name> -n <OADP installed namespace>
   ```

2. Delete the restore that is stuck in progress by running the following command:

   ```
   velero delete restore <restore name>
   ```

   Wait for the completion of the restore job.

Helm install restore job command failed

When you are running the **helm install restore-job clusterrestore-0.1.0.tgz** command, you might encounter the command failing with an error that is similar to the following error:

```
Error: admission webhook "trust.hooks.securityenforcement.admission.cloud.ibm.com" denied the request:
Deny "icr.io/cpopen/cp4waiops/cp4aiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355", no
matching repositories in ClusterImagePolicy and no ImagePolicies in the "velero" namespace
```

If you encounter this error, complete the following steps to resolve the issue:

1. Uninstall the **restore-job** job by running the following command:

   ```
   helm uninstall restore-job -n $OADP_NAMESPACE
   ```

2. Export an environment variable for the image.

   For an online deployment:

   ```
   export REGISTRY=icr.io/cpopen/cp4waiops/cp4aiops-bcdr
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   For an offline deployment:

   ```
   export REGISTRY=$TARGET_REGISTRY
   export BCDR_IMAGE=${REGISTRY}/<bcdr_image>
   ```

   Where **<bcdr_image>** is the name of the backup and restore image, as given in the backup helm chart **values.yaml** file, in the form **cp4waiops-bcdr@{digest}**. An example value for BCDR_IMAGE is **icr.io/cpopen/cp4waiops/cp4waiops-bcdr@sha256:294a42a851a2717ebbc68528ab3c6bcb1ba48114ff058f1c1b537dc6aa167355**.

3. Create a **restore-image-policy.yaml** file and add the following content within the file:

   ```
   apiVersion: securityenforcement.admission.cloud.ibm.com/v1beta1
   kind: ClusterImagePolicy
   metadata:
     name: restore-image-policy
   spec:
    repositories:
     - name: ${BCDR_IMAGE}
       policy:
   ```

4. Apply the policy by running the following command:

   ```
   oc apply -f restore-image-policy.yaml
   ```

5. Deploy the restore job by running the following command:

   ```
   helm install restore-job clusterrestore-0.1.0.tgz
   ```

Cassandra restore fails with `org.apache.cassandra.io.FSReadError` exception

Policies are not restored after restore completed. Although there were a couple of key repair failures, the log indicated the Cassandra restore completed. However, the policies from the backup cluster were not restored.

You can encounter an issue where the Cassandra restore fails. If this issue occurs, the **aiops-topology-cassandra-2** pod is in **0/1** status and the pod log contains an error message that is similar to the following error message:

```
ERROR [CompactionExecutor:8] 2022-11-29 21:39:17,324 CassandraDaemon.java:244 - Exception in thread
Thread[CompactionExecutor:8,1,main]
org.apache.cassandra.io.FSReadError: java.io.IOException: Channel not open for writing - cannot extend file to required
size
```

If this error occurs, complete the following steps for the Cassandra statefulset:

1. Scale down the statefulset **aiops-topology-cassandra** to **0**.

   Important: Make a note of the current scaling of the Cassandra statefulset before you scale down.

   ```
   oc scale statefulsets aiops-topology-cassandra --replicas 0 -n <namespace>
   ```

   Where: **<namespace>** is the namespace where IBM Cloud Pak for AIOps is installed.

2. Increase the statefulset memory limit to 32 GB.

   1. Access the resource for editing:

      ```
      oc edit statefulset aiops-topology-cassandra -n <namespace>
      ```

   2. Increase the memory limit:

3. Scale the statefulset back to the initial number of replicas.

   ```
   oc scale statefulsets aiops-topology-cassandra --replicas=<number_of_replicas> -n <namespace>
   ```

   Where:

   - **<namespace>** is the namespace where IBM Cloud Pak for AIOps is installed.
   - **<number_of_replicas>** is the number of replicas the StatefulSet it to be scaled up to.

4. Run the restore again.

5. Scale down the statefulset **aiops-topology-cassandra** to **0** again.

   ```
   oc scale statefulsets aiops-topology-cassandra --replicas 0 -n <namespace>
   ```

6. Change the statefulset memory limit to 16 GB .

   1. Access the resource for editing:

      ```
      oc edit statefulset aiops-topology-cassandra -n <namespace>
      ```

   2. Decrease the memory limit to 16 GB.

7. Scale the statefulset back to the initial number of replicas.

   ```
   oc scale statefulsets aiops-topology-cassandra --replicas=<number_of_replicas> -n <namespace>
   ```

   Where:

   - **<namespace>** is the namespace where IBM Cloud Pak for AIOps is installed.
   - **<number_of_replicas>** is the number of replicas the StatefulSet it to be scaled up to.

Integrations missing after a restore

After you complete a full restore, if you do not see all of the data integrations that you expect, run the command to restore data for the **Metastore** component to restore the integrations. For instructions, see Restoring individual components.

Netcool integration is missing details after restore

If you had a Netcool integration defined, then the Netcool integration might be missing some details after restore, such as the ObjectServer details. If you try to edit these details then the test still fails. To resolve this problem, delete the Netcool integration, and then create a new Netcool integration.

Restore fails with lifecycletrigger: Not Ready

If **lifecycletrigger** is showing *Not Ready* after the restore, then run the following command:

```
oc patch lifecycletrigger aiops --type=json --patch="$(oc get lifecycletrigger aiops -o jsonpath='{"
[{"}"op":"add","path":"/spec/cancelJobs","value":[{range .status.jobs[*]}"{.jid}",{end}]}]' | sed 's/,]/]/g')"
```

Cannot login to the Cloud Pak for AIOps console on the restore cluster

After the restore, the IBM Cloud Pak for AIOps console is inaccessible and there is an error similar to the following:

```
`CWOAU0061E: The OAuth service provider could not find the client because the client name is not valid`
```

Solution: Run the following steps on the restore cluster:

1. Export an environment variable containing your project's name.

   ```
   export PROJECT=<project>
   ```

   Where **<project>** is the namespace (project) that IBM Cloud Pak for AIOps is deployed in on the restore cluster.

2. Delete the platform pods.

   ```
   oc delete pod -n ${PROJECT} -l component=platform-auth-service
   oc delete pod -n ${PROJECT} -l component=platform-identity-management
   oc delete pod -n ${PROJECT} -l component=platform-identity-provider
   ```

3. Update and delete the **iam-config-job** YAML.

   ```
   oc get  -n ${PROJECT} job iam-config-job  -o json > /tmp/iam-config-job.json
   oc -n ${PROJECT} delete job iam-config-job
   jq 'del(.metadata.creationTimestamp) | del(.metadata.managedFields) | del(.metadata.resourceVersion) |
   del(.metadata.uid) | del(.spec.selector) | del(.spec.template.metadata.labels) | del(.status)' /tmp/iam-config-
   job.json > /tmp/updated-iam-config-job.json
   ```

4. Wait for a few seconds and then apply the modified YAML to rerun **iam-config-job**.

   ```
   oc -n ${PROJECT} apply -f /tmp/updated-iam-config-job.json
   oc -n ${PROJECT} get pods | grep iam-config-job
   ```

Policy configuration is not retained on the restored deployment

Incident policies that previously had a ticket integration are missing the ticket integration on the restored deployment. If GitHub or ServiceNow are configured, then external tickets are not created in them. The policy page has a **Warning** similar to the following example:

```
The previously selected ticket connection Github -mygit is no longer available. Please check the status of your
connector.
```

Solution: From the IBM Cloud Pak for AIOps console, edit the policy and add the connection that is shown in the warning.

Troubleshooting the Infrastructure Automation restore

If you are also restoring Infrastructure Automation data and encounter an issues with the restore process for Infrastructure Automation or encounter an issue with data not being available or processed after the restore, see Troubleshooting the Infrastructure Automation restore

In addition, review the Known issues with the backup and restore process.

Known issues with the backup and restore process

- Elasticsearch health status yellow after restore

Elasticsearch health status yellow after restore

When you are restoring an Elasticsearch backup to a new single node Elasticsearch cluster, the Elasticsearch database might not work as expected. Instead, the Elasticsearch cluster health shows a yellow status after the restore completes.

Upgrading IBM Cloud Pak for AIOps backup and restore artifacts

Use this procedure if you want to run backup or restore on an upgraded IBM Cloud Pak® for AIOps deployment.

If you run a backup or restore on an IBM Cloud Pak for AIOps deployment, the backup and restore scripts must always be the same version as your deployment. For example, if you run backup on a IBM Cloud Pak for AIOps v4.8.0 deployment, you must use a v4.8.0 backup script.

If you previously set up backup or restore on a deployment that you have now upgraded, then you must clean up any existing backup or restore artifacts. If you then want to run a new backup or restore, you must get the new version of the backup or restore scripts.

Note: If you have never set up backup or restore and you want to run backup or restore, then use the instructions in IBM Cloud Pak for AIOps backup and restore.

Set up backup on an upgraded IBM Cloud Pak for AIOps deployment

Use the following steps to upgrade your backup artifacts.

1. Uninstall the backup helm chart.

   Run the following command in the namespace that **Red Hat OpenShift APIs for Data Protection** (OADP) is installed in.

   ```
   helm uninstall backup-job
   ```

2. Set up backup for IBM Cloud Pak for AIOps v4.8.0.

   If you need to run backup for IBM Cloud Pak for AIOps v4.8.0, follow the instructions in Backing up IBM Cloud Pak for AIOps data.

   Important: The **cp4waiops-bcdr** image must be the same version as your IBM Cloud Pak for AIOps deployment. Follow these instructions to ensure that your **cp4waiops-bcdr** image is v4.8.0 for your IBM Cloud Pak for AIOps v4.8.0 deployment.

Set up restore on an upgraded IBM Cloud Pak for AIOps deployment

Use the following steps to upgrade your restore artifacts.

1. Uninstall the restore helm chart.

   Run the following command in the namespace that **Red Hat OpenShift APIs for Data Protection** (OADP) is installed in.

   ```
   helm uninstall restore-job
   ```

2. Set up restore for IBM Cloud Pak for AIOps v4.8.0.

   If you need to run restore for IBM Cloud Pak for AIOps v4.8.0, follow the instructions in Restoring IBM Cloud Pak for AIOps.

   Important: The **cp4waiops-bcdr** image must be the same version as your IBM Cloud Pak for AIOps deployment. Follow these instructions to ensure that your **cp4waiops-bcdr** image is v4.8.0 for your IBM Cloud Pak for AIOps v4.8.0 deployment.

Multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps

Multi-region cold standby disaster recovery (DR) enables the restoration of your IBM Cloud Pak for AIOps deployment if an unrecoverable failure impacts the deployment or its hosting cluster, data center, or region.

Overview

The multi-region cold standby disaster recovery solution for IBM Cloud Pak for AIOps uses IBM Fusion to create and restore backups of your IBM Cloud Pak for AIOps deployment and its data. For more information about IBM Fusion, see the Fusion documentation.

IBM Fusion uses the concept of a hub and spoke. A Red Hat® OpenShift® Container Platform cluster that has an IBM Fusion backup & restore service installation on it is the hub cluster. The hub manages the backups, and backups can also be taken or restored on a hub cluster. A Red Hat OpenShift cluster that has an IBM Fusion backup & restore agent installation on it is a spoke cluster. Backups can be taken or restored on a spoke, but the spoke cannot manage the backups.

IBM Fusion takes a backup of your IBM Cloud Pak for AIOps deployment, and stores it in external object storage. If a problem occurs that renders your IBM Cloud Pak for AIOps deployment unusable, then the backup can be restored to a Red Hat OpenShift spoke cluster. The entire IBM Cloud Pak for AIOps deployment is restored, along with its data.

Entitlement to IBM Cloud Pak for AIOps provides you with entitlement to the IBM Fusion Data Foundation service in internal deployment mode only. To implement multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps, you must purchase a full IBM Fusion license for access to the backup and disaster recovery features. For more information, see the license terms.

Restrictions

- IBM Fusion and the IBM Cloud Pak for AIOps deployment to be backed up must be installed on the same Red Hat OpenShift cluster.
- The backup and restore procedures cannot be used on offline (air gapped) deployments of IBM Cloud Pak for AIOps.
- The backup and restore procedures cannot be used if IBM Cloud Pak for AIOps is installed with Infrastructure Automation.
- The backup and restore procedures cannot be used on `AllNamespace` deployments of IBM Cloud Pak for AIOps. For more information about installation modes, see Operator installation mode.
- If IBM Cognos® Analytics is installed, it is not backed up or recovered.
- User interface customizations are not backed up or restored.

Before you begin

Red Hat OpenShift

Ensure that you meet the following prerequisites for the hub cluster, and also for the spoke cluster if you are using one:

- The Red Hat OpenShift version is supported by IBM Cloud Pak for AIOps and IBM Fusion v2.8.x or v2.9.x.
  - IBM Cloud Pak for AIOps: For more information, see Supported Red Hat OpenShift versions.
  - IBM Fusion: For more information, see Prerequisites in the IBM Fusion documentation.
- The Red Hat OpenShift command-line interface (oc) is installed. For more information, see the instructions in Getting started with the Red Hat OpenShift CLI in the Red Hat OpenShift documentation.
- You are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).

Storage

Ensure that you meet the following prerequisites for your persistent and external storage.

- In addition to your IBM Cloud Pak for AIOps deployment's persistent storage, you must have external object storage available for IBM Fusion to use as the backup storage location. This is where the IBM Cloud Pak for AIOps volume backups will be stored. This can be any S3 compatible storage, or Microsoft® Azure Blob Storage.
- The amount of external object storage that is required is affected by the amount of data to be stored, the change rate of the data, and the storage efficiencies that can be made from compression and deduplication. As a guide, for a 30-day retention period, you must have object storage capacity equivalent to a minimum of 125% of your IBM Cloud Pak for AIOps deployment's persistent storage. For example, if you have 100 GB of persistent storage for IBM Cloud Pak for AIOps, then you must have 125 GB of object storage available for backups.
- The persistent storage that IBM Cloud Pak for AIOps uses must be Container Storage Interface (CSI) compatible, and must support volume snapshot and restore. The CSI driver must be v1 or higher.
- If you are using Portworx as your storage provider, then IBM Fusion must be at v2.9.0 or higher, or backup and restore will fail.
- PersistentVolumes (PVs) must be created with `volumeMode` set to *Filesystem*.
- The storage class that is used by IBM Cloud Pak for AIOps must have `volumeBindingMode` set to *Immediate*, and `allowVolumeExpansion` set to *true*.

For more information, see the `Backup & Restore` section in System requirements in the IBM Fusion documentation.

Backup and restore procedures

Use the instructions in the following sections to backup or restore an IBM Cloud Pak for AIOps deployment.

- Multi-region cold standby disaster recovery: Backing up IBM Cloud Pak for AIOps
- Multi-region cold standby disaster recovery: Restoring IBM Cloud Pak for AIOps
- Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps

Multi-region cold standby disaster recovery: Backing up IBM Cloud Pak for AIOps

Use IBM Fusion to create a backup of your IBM Cloud Pak for AIOps deployment.

Backup procedure

Ensure that you meet the prerequisites in Before you begin.

Use the following instructions to install IBM Fusion on the same Red Hat OpenShift cluster as IBM Cloud Pak for AIOps, and then create a backup of IBM Cloud Pak for AIOps.

1. Ensure that you have a VolumeSnapshotClass
2. Install IBM Fusion
3. Deploy the IBM Fusion Backup & Restore service
4. Configure the IBM Fusion Backup & Restore service for IBM Cloud Pak for AIOps

1. Ensure that you have a VolumeSnapshotClass

To enable IBM Fusion backups, you must have a **VolumeSnapshotClass** defined for one of the storage classes that host IBM Cloud Pak for AIOps. For more information, see Prerequisites in the IBM Fusion documentation.

Run the following command to check whether a **VolumeSnapshotClass** is defined already:

```
oc get volumesnapshotclass
```

If the preceding command does not return anything, then you do not have a **VolumeSnapshotClass** defined. Refer to your storage provider's documentation to create one.

2. Install IBM Fusion

You must install IBM Fusion v2.8.x or v2.9.x.

Follow the *Installing* instructions for your Red Hat OpenShift deployment type in Deploying IBM Fusion in the IBM Fusion documentation. Accept the default values.

Note: As you are installing IBM Fusion on the same Red Hat OpenShift cluster as IBM Cloud Pak for AIOps, you already have an entitlement pull secret configured.

3. Deploy the IBM Fusion Backup & Restore service

1. Install the IBM Fusion Backup & Restore service.

   Follow the instructions in Backup and restore hub in the IBM Fusion documentation.

   The **ibm-backup-restore** project (namespace) is created, and the backup and restore service is installed in that project.

2. Configure the backup storage location for IBM Fusion to store the IBM Cloud Pak for AIOps backups in.

   The backup storage location must be external object storage, and can be any S3 compatible storage or Microsoft® Azure Blob Storage.

   Follow the instructions in Adding a backup storage location in the IBM Fusion documentation.

3. Create a backup policy.

   The backup policy specifies the backup location, frequency, and retention period of the backup. Specify the backup storage location that you created in the previous step as the backup location.

   Follow the instructions in Creating backup policy in the IBM Fusion documentation.

4. Select the IBM Cloud Pak for AIOps application that you want to backup, and assign the backup policy to it.

   Follow the instructions in Selecting applications for protection in the IBM Fusion documentation.

   Important: Before you select **Assign** in the user interface, you must deselect **Run backup now** to prevent the backup from running immediately.

5. Find the name of your policy assignment.

   Your policy assignment name is the IBM Cloud Pak for AIOps installation namespace concatenated with the backup policy name. Run the following command to find it, and then make a note of it:

   ```
   oc get fpa -n ibm-spectrum-fusion-ns
   ```

4. Configure the IBM Fusion Backup & Restore service for IBM Cloud Pak for AIOps

1. Run the following commands to set the environment variables that you need.

   ```
   export PROJECT_CP4AIOPS=<namespace>
   export CUSTOM_PROFILE=<custom_profile>
   export POLICY_ASSIGNMENT_NAME=<policy_assignment_name>
   ```

   Where:

   - **<namespace>** is the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in, for example **cp4aiops**.
   - **<custom_profile>** is blank unless IBM Sales representatives and Business Partners used the custom sizing tool to supply you with a custom profile ConfigMap to customize your deployment. If you were supplied with a custom profile ConfigMap, then this is the name of your custom profile ConfigMap, usually **aiops-custom-size-profile**.
   - **<policy_assignment_name>** is the policy assignment name that you found in the previous step.

2. Find your installation name and set an environment variable for it.

   1. Find the name of your IBM Cloud Pak for AIOps installation.

      ```
      oc get installation -n ${PROJECT_CP4AIOPS}
      ```

      Example output, where **ibm-cp-aiops** is the name of the IBM Cloud Pak for AIOps installation:

      ```
      NAME          PHASE    LICENSE   STORAGECLASS STORAGECLASSLARGEBLOCK AGE
      ibm-cp-aiops  Running  Accepted  rook-cephfs  rook-ceph-rbd          34h
      ```

   2. Export an environment variable with the name of your installation.

      ```
      export INSTALLATION_NAME=<name>
      ```

Where **<name>** is the name returned by the previous command, for example **ibm-cp-aiops**.

3. Run the following commands to add labels to IBM Cloud Pak for AIOps resources so that they are correctly identified.

```
oc -n $PROJECT_CP4AIOPS label secret ${INSTALLATION_NAME}-edb-secret manual=${INSTALLATION_NAME}-edb-secret
oc -n $PROJECT_CP4AIOPS label secret ${INSTALLATION_NAME}-redis-secret manual=${INSTALLATION_NAME}-redis-secret
oc -n $PROJECT_CP4AIOPS label secret ibm-zen-secret-jwks manual=ibm-zen-secret-jwks
oc -n $PROJECT_CP4AIOPS label secret ibm-zen-secret-jwt manual=ibm-zen-secret-jwt
oc -n $PROJECT_CP4AIOPS label secret ibm-zen-secret-jwt-private manual=ibm-zen-secret-jwt-private
oc -n $PROJECT_CP4AIOPS label secret aiopsedge-config-encryption-history manual=aiopsedge-config-encryption-history
oc -n $PROJECT_CP4AIOPS label secret platform-auth-ldaps-ca-cert manual=platform-auth-ldaps-ca-cert
oc -n $PROJECT_CP4AIOPS label secret ibm-entitlement-key manual=ibm-entitlement-key-secret
oc -n $PROJECT_CP4AIOPS label subscriptions.operators.coreos.com ibm-aiops-orchestrator manual=ibm-aiops-
orchestrator
```

4. Download the IBM Cloud Pak for AIOps backup and restore IBM Fusion recipe.

   The IBM Fusion recipe defines the sequence of actions and checks that IBM Fusion must use for the backup and restore of IBM Cloud Pak for AIOps resources and PVCs.

   Download the recipe **aiops-backup-restore.yaml**, from github.com/IBM.

5. Adjust the recipe if you have a non-default installation name.

   If your installation name is not **ibm-cp-aiops**, then edit the recipe that you downloaded, and alter all occurences of **ibm-cp-aiops** to be your installation name.

6. Adjust the recipe for custom sizing.

   IBM Sales representatives and Business Partners may have used a custom sizing tool to supply you with a custom profile to customize your IBM Cloud Pak for AIOps deployment at installation time.

   If IBM Sales representatives and Business Partners did not supply you with a custom profile, then skip this step.

   If IBM Sales representatives and Business Partners supplied you with a custom profile, then add a label to the custom profile ConfigMap in your IBM Cloud Pak for AIOps deployment. Run the following command:

```
oc label cm ${CUSTOM_PROFILE} cm=aiops-custom-size-profile
```

7. Create the IBM Cloud Pak for AIOps recipe custom resource.

   Run the following command to create the recipe custom resource.

```
oc apply -f aiops-backup-restore.yaml
```

8. Configure your policy assignment to use the IBM Cloud Pak for AIOps back and restore recipe.

   Patch the policy assignment with the details of the IBM Cloud Pak for AIOps back and restore recipe.

```
oc -n ibm-spectrum-fusion-ns patch policyassignment ${POLICY_ASSIGNMENT_NAME} --type merge  -p '{"spec":{"recipe":
{"name":"aiops-backup-restore-recipe", "namespace":"ibm-spectrum-fusion-ns"}}}'
```

What to do next

Backups occur according to the schedule that you set in your policy. If you want to run a backup immediately, follow the instructions in Backup now.

You can monitor the progress of the backup from **Backup & restore** > **Jobs** in the IBM Fusion user interface.

To view the IBM Fusion logs, or to see the resources that were backed up, see Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps.

Multi-region cold standby disaster recovery: Restoring IBM Cloud Pak for AIOps

Use IBM Fusion to restore your IBM Cloud Pak for AIOps deployment from backup.

Restore procedure

IBM Fusion recovers the IBM Cloud Pak for AIOps instance to a working state on a target cluster, along with its data. Your target cluster can be the hub cluster, or a different Red Hat OpenShift cluster (a spoke).

Ensure that you meet the prerequisites in Before you begin. User interface customizations are not restored.

Follow the steps for Restoring to the hub cluster or Restoring to a spoke cluster.

Restoring to the hub cluster

If you are restoring IBM Cloud Pak for AIOps to the same Red Hat OpenShift cluster that you created your backup on, then you must completely uninstall your IBM Cloud Pak for AIOps deployment, and remove the deployment namespaces from it (usually **cp4aiops**). The Red Hat OpenShift cluster must not have any residual IBM Cloud Pak for AIOps artifacts. For more information, see Uninstalling IBM Cloud Pak for AIOps.

1. Get the entitlement key.

   Follow the instructions in Obtaining the entitlement key in the IBM Fusion documentation.

2. Create a global pull secret.

   Follow the instructions in Creating image pull secret in the IBM Fusion documentation.

3. Create the required catalogs.

   Follow the instructions in Create the catalog sources.

4. Install Cert Manager

   Skip this step if a certificate manager is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager, then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

   For more information about IBM Cloud Pak® foundational services Cert Manager hardware requirements, see IBM Certificate Manager (cert-manager) hardware requirements in the IBM Cloud Pak foundational services documentation.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-cert-manager
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-cert-manager-operator-group
        namespace: ibm-cert-manager
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      metadata:
        name: ibm-cert-manager-operator
        namespace: ibm-cert-manager
      spec:
        channel: v4.2
        installPlanApproval: Automatic
        name: ibm-cert-manager-operator
        source: ibm-cert-manager-catalog
        sourceNamespace: openshift-marketplace
      EOF
      ```

   2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

      ```
      oc -n ibm-cert-manager get pods
      ```

      Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

      ```
      NAME                                         READY   STATUS    RESTARTS   AGE
      cert-manager-cainjector-674854c49d-vstq4     1/1     Running   0          8d
      cert-manager-controller-646d4bd6fd-zwmqm     1/1     Running   0          8d
      cert-manager-webhook-8598787c8-s41kt         1/1     Running   0          8d
      ibm-cert-manager-operator-c96957695-dkxnm    1/1     Running   0          8d
      ```

5. Install the License Service

   Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-licensing-operator-group
        namespace: ibm-licensing
      spec:
        targetNamespaces:
        - ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      ```

```
metadata:
  name: ibm-licensing-operator-app
  namespace: ibm-licensing
spec:
  channel: v4.2
  installPlanApproval: Automatic
  name: ibm-licensing-operator-app
  source: ibm-licensing-catalog
  sourceNamespace: openshift-marketplace
EOF
```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-licensing get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services License Service installation:

   ```
   NAME                                                  READY   STATUS    RESTARTS   AGE
   ibm-licensing-operator-db4cd746c-xzmlf                1/1     Running   0          8d
   ibm-licensing-service-instance-596b99588f-76cc5       1/1     Running   0          8d
   ```

For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

6. Update the IBM Fusion Backup & Restore transaction manager cluster roles.

   Run the following command:

   ```
   oc get clusterrole transaction-manager-ibm-backup-restore -o json | jq '.rules += [{"verbs":
   ["get","list"],"apiGroups":["orchestrator.aiops.ibm.com"],"resources":["installations"]},{"verbs":
   ["get","list"],"apiGroups":["ai-manager.watson-aiops.ibm.com"],"resources":["aimanagers"]},{"verbs":
   ["get","list"],"apiGroups":["lifecycle.ir.aiops.ibm.com"],"resources":["lifecycleservices"]}]' | oc apply -f -
   ```

7. Follow the instructions in Restoring the application in the IBM Fusion documentation.

   Select **Same cluster**, and then for **Project destination** select *Use the same project the application is already using*. Accept the default values for the other fields.

   Note: You might notice that the `aiops-configmaps` resource group shows as failed under the **Restore sequence** section of the IBM Cloud Pak for AIOps restore recipe but the overall restore is successful and works as intended.

8. Delete any duplicate observer jobs on the restored cluster.

   1. Log in to IBM Cloud Pak for AIOps console.
   2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
   3. For any duplicate jobs, click the options menu (three vertical dots) and click **Delete**.

9. From the IBM Cloud Pak for AIOps console, select and edit each `incident` policy that utilises a `ticket` integration, and manually reassign the relevant ticketing system (Github/ServiceNow).

Restoring to a spoke cluster

If you are restoring IBM Cloud Pak for AIOps to a different cluster, ensure that your target cluster meets the prerequisites for an IBM Cloud Pak for AIOps deployment, and then install IBM Fusion and the IBM Fusion backup agent on it.

1. Spoke cluster prerequisites

- You must have the same storage provider and storage classes available for your target spoke cluster as you did for your IBM Cloud Pak for AIOps deployment on the hub cluster.
- The target spoke cluster must have the same deployment platform and Red Hat OpenShift version as the source hub cluster. Review the Planning section and ensure that the environment that you are restoring to meets the system requirements.
- The Red Hat OpenShift cluster that you restore on must not have a previous IBM Cloud Pak for AIOps deployment on it, and must not have any residual IBM Cloud Pak for AIOps artifacts or deployment namespaces (usually `cp4aiops`). If you need to uninstall IBM Cloud Pak for AIOps, see the instructions in Uninstalling IBM Cloud Pak for AIOps.

2. Install IBM Fusion on the target spoke cluster

   1. Get the entitlement key.

      Follow the instructions in Obtaining the entitlement key in the IBM Fusion documentation.

   2. Create a global pull secret.

      Follow the instructions in Creating image pull secret in the IBM Fusion documentation.

   3. Create the required catalogs.

      Follow the instructions in Create the catalog sources.

   4. Install IBM Fusion.

      You must install IBM Fusion v2.8.x or v2.9.x.

Follow the **Installing** instructions for your Red Hat OpenShift deployment type in Deploying IBM Fusion in the IBM Fusion documentation. Accept the default values.

3. Install Cert Manager

   Skip this step if you already have a certificate manager installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on. If you do not have a certificate manager then you must install one. The IBM Cloud Pak® foundational services Cert Manager is recommended, and can be installed with the following steps.

   For more information about IBM Cloud Pak® foundational services Cert Manager, see Certificate Management in the IBM Cloud Pak foundational services documentation.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-cert-manager
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-cert-manager-operator-group
        namespace: ibm-cert-manager
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      metadata:
        name: ibm-cert-manager-operator
        namespace: ibm-cert-manager
      spec:
        channel: v4.2
        installPlanApproval: Automatic
        name: ibm-cert-manager-operator
        source: ibm-cert-manager-catalog
        sourceNamespace: openshift-marketplace
      EOF
      ```

   2. Run the following command to ensure that the IBM Cloud Pak® foundational services Cert Manager pods have a **STATUS** of *Running* before proceeding to the next step.

      ```
      oc -n ibm-cert-manager get pods
      ```

      Example output for a successful IBM Cloud Pak® foundational services Cert Manager installation:

      ```
      NAME                                       READY   STATUS    RESTARTS   AGE
      cert-manager-cainjector-674854c49d-vstq4   1/1     Running   0          8d
      cert-manager-controller-646d4bd6fd-zwmqm   1/1     Running   0          8d
      cert-manager-webhook-8598787c8-s4lkt       1/1     Running   0          8d
      ibm-cert-manager-operator-c96957695-dkxnm  1/1     Running   0          8d
      ```

4. Install the License Service

   Skip this step if the IBM Cloud Pak® foundational services License Service is already installed on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   IBM Cloud Pak for AIOps requires the installation of the IBM Cloud Pak foundational services License Service. You must install the IBM Cloud Pak foundational services License Service on the Red Hat OpenShift cluster that you are installing IBM Cloud Pak for AIOps on.

   1. Run the following command to create the resource definitions that you need:

      ```
      cat << EOF | oc apply -f -
      apiVersion: v1
      kind: Namespace
      metadata:
        name: ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: ibm-licensing-operator-group
        namespace: ibm-licensing
      spec:
        targetNamespaces:
        - ibm-licensing
      ---
      apiVersion: operators.coreos.com/v1alpha1
      kind: Subscription
      metadata:
        name: ibm-licensing-operator-app
        namespace: ibm-licensing
      spec:
        channel: v4.2
        installPlanApproval: Automatic
        name: ibm-licensing-operator-app
        source: ibm-licensing-catalog
        sourceNamespace: openshift-marketplace
      EOF
      ```

2. Run the following command to ensure that the IBM Cloud Pak® foundational services License Server pods have a **STATUS** of *Running* before proceeding to the next step.

   ```
   oc -n ibm-licensing get pods
   ```

   Example output for a successful IBM Cloud Pak® foundational services License Service installation:

   ```
   NAME                                          READY   STATUS    RESTARTS   AGE
   ibm-licensing-operator-db4cd746c-xzmlf        1/1     Running   0          8d
   ibm-licensing-service-instance-596b99588f-76cc5   1/1     Running   0          8d
   ```

For more information about the IBM Cloud Pak® foundational services License Service, see License Service in the IBM Cloud Pak foundational services documentation.

5. Get connection YAML from the hub cluster.

   On the hub cluster, follow the **`Use the Fusion UI`** instructions in Connect clusters in the IBM Fusion documentation.

   When you have copied the connection snippet, return to these steps. The connection snippet is used in the next step to connect the hub and spoke clusters.

6. Install the **`Backup & Restore Agent`** on the spoke cluster, and connect the spoke cluster to the hub cluster.

   On the spoke cluster, follow the procedure in Backup & Restore spoke in the IBM Fusion documentation.

   For the **Hub Connection Snippet** field, use the connection snippet that you copied in the previous step. The storage classes must be the same storage classes that the IBM Cloud Pak for AIOps deployment on the hub cluster used.

7. On the spoke cluster, update the IBM Fusion Backup & Restore transaction manager cluster roles.

   Run the following command:

   ```
   oc get clusterrole transaction-manager-ibm-backup-restore -o json | jq '.rules += [{"verbs":
   ["get","list"],"apiGroups":["orchestrator.aiops.ibm.com"],"resources":["installations"]},{"verbs":
   ["get","list"],"apiGroups":["ai-manager.watson-aiops.ibm.com"],"resources":["aimanagers"]},{"verbs":
   ["get","list"],"apiGroups":["lifecycle.ir.aiops.ibm.com"],"resources":["lifecycleservices"]}]' | oc apply -f -
   ```

8. Follow the instructions in Restoring the application in the IBM Fusion documentation, and wait for the restore to complete.

   Select **New cluster**, and then accept the default values for the other fields.

   Note: You might notice that the **`aiops-configmaps`** resource group shows as failed under the **Restore sequence** section of the IBM Cloud Pak for AIOps restore recipe but the overall restore is successful and works as intended.

9. Redeploy remote integrations.

   Re-run the bootstrap procedure for any remote connections that are configured.

   1. Log in to IBM Cloud Pak for AIOps console.
   2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
   3. For each remote integration, click the integration type on the **Manage integrations** tab of the Integrations page, then:
      1. Click the **Download** link in the **Remote deployment script** column for the integration.
      2. Click **Download as a sh-file** to download the deployment script as a **`bootstrap.sh`** file.
      3. From the Red Hat OpenShift CLI, switch to the target project (namespace).

         ```
         oc project <namespace>
         ```

         Where **`<namespace>`** is the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in, for example *cp4aiops*.

      4. Run the **`bootstrap.sh`** deployment script.

10. If you have secure tunnel connections, then re-create them. For more information, see Create the secure tunnel connection on your restored cluster.

11. Delete any duplicate observer jobs on the restored cluster.

    1. Log in to IBM Cloud Pak for AIOps console.
    2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
    3. For any duplicate jobs, click the options menu (three vertical dots) and click **Delete**.

12. From the IBM Cloud Pak for AIOps console, select and edit each **`incident`** policy that utilises a **`ticket`** integration, and manually reassign the relevant ticketing system (Github/ServiceNow).

What to do next

The restore takes a few hours to run. You are notified on the IBM Fusion user interface (UI) when the restore is complete. You can also monitor the progress of the restore from **Backup & restore** > **Jobs** in the IBM Fusion UI.

Important: If you restored to a spoke cluster, the URL and password for accessing the IBM Cloud Pak for AIOps console are different from the URL and password that you used on the hub cluster. Follow the steps in Access the Cloud Pak for AIOps console to find the new URL and password.

(Optional) After the restore is complete, you can verify the status of your deployment by using the steps in Verify your installation (CLI) or Verify your installation (console).

To view the IBM Fusion logs, or to see the resources that were backed up or restored, see Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps.

Troubleshooting multi-region cold standby disaster recovery for IBM Cloud Pak for AIOps

Troubleshoot your IBM Fusion backup or restore of IBM Cloud Pak for AIOps.

General troubleshooting

- Retrieve backup or restore logs
- List resources that were backed up or restored

Restore issues

- Policy configuration is not retained on the restored deployment
- PostgresSQL instance is out of sync after fusion restore

General troubleshooting tips

Retrieve backup or restore logs

1. Download **`getRecipeWorkflow.sh`** from github.com/IBM.
2. Obtain the job UID for the backup or restore job. The job UID can be obtained from the IBM Fusion user interface, or from the command-line.

   From the IBM Fusion user interface:

   1. Select **Applications** from the left navigation menu.
   2. Select the Application from the table, for example **`filebrowser`**.
   3. Select **Backups**.
   4. For the backup or restore job of interest, select the right ... menu and select **Details**.
   5. Click the job name, for example **`filebrowser-demo-daily-apps.test.stglabs.ibm.com-202311220800`**.
   6. Note the **Job ID** in the **Details** window, for example: **`63eb6ea5-dc24-41ef-9fb7-199c48df1508`**.`

   From the command-line:

   1. Open the YAML file for the backup custom resource. For example:

      ```
      oc get fbackup filebrowser-demo-daily-apps.test.stglabs.ibm.com-202311220800 -n ibm-spectrum-fusion-ns -o yaml
      ```

   2. Locate the **`uid`** in **`spec: metatdata`**, for example: **`uid: 63eb6ea5-dc24-41ef-9fb7-199c48df1508`**.
3. Run **`getRecipeWorkflow.sh`** with the job UID.

   ```
   getRecipeWorkflow.sh <job_type> <job_uid>
   ```

   Where

   - **`<job_type>`** is **`backup`** or **`restore`**.
   - **`<job_uid>`** is the job UID that you obtained.

   Example command:

   ```
   getRecipeWorkflow.sh backup 63eb6ea5-dc24-41ef-9fb7-199c48df1508
   ```

List resources that were backed up or restored

1. Download **`getResources.sh`** from github.com/IBM.
2. Use step 2 in Retrieve backup or restore logs to get the job UID.
3. Run **`getResources.sh`** with the job UID.

   ```
   getReesources.sh <job_type> <job_uid>
   ```

   Where

   - **`<job_type>`** is **`backup`** or **`restore`**.

- `<job_uid>` is the job UID that you obtained.

Example command:

```
getResources.sh backup 63eb6ea5-dc24-41ef-9fb7-199c48df1508
```

Troubleshooting restore issues

Policy configuration is not retained on the restored deployment

Incident policies that previously had a ticket integration are missing the ticket integration on the restored deployment. If GitHub or ServiceNow are configured, then external tickets are not created in them. The policy page has a **Warning** similar to the following example:

```
The previously selected ticket connection Github -mygit is no longer available. Please check the status of your
connector.
```

Solution: From the IBM Cloud Pak for AIOps console, edit the policy and add the connection that is shown in the warning.

PostgresSQL instance is out of sync after fusion restore

After restore, an EDB Postgres instance has a different value for the Log Sequence Number (LSN), which means that it is not synchronized with the other instances.

1. If it is not already installed, install the `kubectl` plug-in.

   Run the following command:

   ```
   curl -sSfL \
   https://github.com/EnterpriseDB/kubectl-cnp/raw/main/install.sh | \
   sudo sh -s -- -b /usr/local/bin
   ```

2. Run the following command to check whether all the EDB Postgres instances are synchronized.

   ```
   oc cnp status ibm-cp-aiops-edb-postgres
   ```

   If a Postgres instance is not synchronized, then the value for `Current LSN` is not the same as the `Current LSN` for the other instances.

   Example output where a Postgres instance is not synchronized: `worker9.ir-backend-backup-acme.com` has a different Log Sequence Number (LSN):

   ```
    Name                          Database  Current     Replication           Status  QoS         Manager  Node
                                  Size      LSN         role                                      Version
    ibm-cp-aiops-edb-postgres-1   83 MB     6/C214B440  Primary               OK      Burstable   1.18.13  worker7.ir-
   backend-backup-acme.com
    ibm-cp-aiops-edb-postgres-2   82 MB     6/C214B440  Standby (async)       OK      Burstable   1.18.13  worker2.ir-
   backend-backup-acme.com
    ibm-cp-aiops-edb-postgres-3   82 MB     6/A124B330  Standby (file based)  OK      Burstable   1.18.13  worker9.ir-
   backend-backup-acme.com
   ```

Solution: If one or more of the Postgres instances are not synchronized, follow the instructions in Postgres EDB database crashes.

Configuring topology resources for production (IBM Cloud Pak for AIOps on OpenShift)

Learn how to configure the File observer for more than 600,000 resources.

Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login` for any steps that use the Red Hat OpenShift command-line interface (CLI).

Configuring the File observer

Additional configuration is required if you are using the File observer for more than 600,000 resources.

If IBM Sales representatives and Business Partners did not use the custom sizing tool to supply you with a custom profile ConfigMap to customize your deployment, then run the following command:

```
cat <<EOF | oc apply -f -
apiVersion: v1
kind: ConfigMap
metadata:
  labels:
    app.kubernetes.io/instance: aiops
    app.kubernetes.io/managed-by: ibm-aiops-orchestrator
    app.kubernetes.io/name: custom-sized-profiles
    app.kubernetes.io/part-of: ibm-aiops
    aiops-custom-size-profile-version: 4.2.0-2023
  name: aiops-custom-size-profile
data:
  # WARNING: Modifications to this ConfigMap may cause your AIOPs installation to become unstable.
  profiles: |
    generatedfor: HA
```

```
    configmaps:
    - name: aiops-topology-sizing
      data:
        asm: |
          file-observer:
            specs:
              replicas: 1
            containers:
              file-observer:
                resources:
                  requests:
                    cpu: 100m
                    memory: 750Mi
                  limits:
                    cpu: 1000m
                    memory: 1750Mi
                env:
                  - name: JVM_ARGS
                    value: -Xms300M -Xmx1400M
EOF
```

If IBM Sales representatives and Business Partners used the custom sizing tool to supply you with a custom profile ConfigMap to customize your deployment, then use the following steps to adjust the value of *JVM_ARGS* for the File observer to *-Xms300M -Xmx1400M*:

1. Log in to your Red Hat OpenShift cluster's console, and then from the **Project** list, select the project (namespace) that IBM Cloud Pak for AIOps is deployed in.
2. Navigate to **Workloads** > **ConfigMaps**.
3. Select the name of your custom profile, usually **aiops-custom-size-profile**, and then click **YAML** to switch to the YAML view. Adjust the value of *JVM_ARGS* for the File observer to *-Xms300M -Xmx1400M* and then click **Save**.

   Example excerpt:

   ```
   - name: aiops-topology-sizing
     data:
       asm: |
         file-observer:
           specs:
             replicas: 1
           containers:
             file-observer:
               resources:
                 requests:
                   cpu: 100m
                   memory: 750Mi
                 limits:
                   cpu: 1000m
                   memory: 1750Mi
               env:
                 - name: JVM_ARGS
                   value: -Xms300M -Xmx1400M
   ```

Health checks and monitoring (IBM Cloud Pak for AIOps on OpenShift)

To prepare your cluster for major operations, such as installing or upgrading IBM Cloud Pak for AIOps, and to maintain your system as you complete Day 2 operations, run health checks and use the available monitoring options to review the health of your IBM Cloud Pak for AIOps deployment and your Red Hat OpenShift Container Platform cluster.

By completing initial and routine health checks of your IBM Cloud Pak for AIOps deployment and cluster, you can gain the following benefits:

- **Ensure installation or upgrade readiness**

  The good health condition of your Red Hat OpenShift Container Platform cluster, storage, and services are prerequisites to ensure the success of any installation or upgrade of IBM Cloud Pak for AIOps. The prerequisites check can help to ensure the readiness of your cluster to proceed with an installation or upgrade.

- **Ensure your system stability**

  Routine health checks monitor your Red Hat OpenShift Container Platform cluster and services to ensure that your system is functioning properly and to identify any potential issues.

- **Maintain your system performance**

  Routine health checks can help to ensure that your IBM Cloud Pak for AIOps deployment and cluster runs optimally by detecting and addressing performance bottlenecks. Your administrators can maintain a historical record to support requests for resource increases.

- **Improve your system reliability**

  By monitoring the health of IBM Cloud Pak for AIOps, you can proactively identify and resolve issues that might potentially cause downtime or data loss.

For more information about running health checks and logging, see the following topics:

- Tools
- Running health checks
- Cluster logging

Tools

To help you with running initial and routine health checks, use the following tools and scripts:

- **Red Hat OpenShift Container Platform web console Monitoring dashboards**

  Red Hat OpenShift Container Platform provides different dashboards and capabilities that are accessible for the web console that can use to monitor and manage your system health.

- **IBM Cloud Pak for AIOps prerequisite checker tool**

  The prerequisite checker tool can be used to validate whether a Red Hat OpenShift Container Platform cluster has the required resources and prerequisites available to enable a successful installation or upgrade of IBM Cloud Pak for AIOps. This tool completes the following checks and generates an installation readiness report:

- **IBM Cloud Pak for AIOps custom sizing tool**

  IBM Sales representatives and Business Partners have access to a custom sizing tool that can assess your runtime requirements and provide a custom profile that scales IBM Cloud Pak for AIOps components. The custom profile is applied when you install IBM Cloud Pak for AIOps. This custom profile cannot be applied after installation, and attempting to do so can break your IBM Cloud Pak for AIOps deployment. By requesting your sales representative use this tool for helping you develop your custom profile, you can help to ensure that you have the allocated resources for handling your workload volumes.

- **IBM Cloud Pak for AIOps MustGather tool**

  The MustGather tool gathers data for IBM Cloud Pak for AIOps deployments. With this tool, you can complete data collection tasks and view analytics on the gathered data. The tool generates a report that shows critical data about the status and health of the cluster and installation. This report allows your to view an overview of your cluster to help you spot and solve problems. This report can provide you with basic cluster analysis to help identify cluster node resource utilization, warnings, and problematic resources. The report can also provide some basic incident analysis.

Running health checks

For guidance on running health checks for different use cases, review the following documentation:

- Installation and upgrade health checks

  Run prerequisite checks and health checks to ensure that your cluster is ready to begin an installation or upgrade of IBM Cloud Pak for AIOps.

- Proactive health checks

  Complete routine health checks and use the available monitoring capabilities to track the ongoing status of your deployment and cluster to maintain the health of your system.

- Reactive health checks

  When you encounter any issues with the health of your IBM Cloud Pak for AIOps deployment or Red Hat OpenShift Container Platform cluster, run the MustGather tool to gather data about the health and details of your deployment and cluster:

Self monitoring

Review the following different ways to monitor your IBM Cloud Pak for AIOps installation:

- Self-monitoring with alerts

  Since Cloud Pak for AIOps runs on OpenShift Container Platform, you can use the inbuilt Alertmanager feature of OpenShift Container Platform to monitor and send alerts to Cloud Pak for AIOps when a problem occurs in the underlying infrastructure.

- Self-monitoring with topology

  Create a topology visualization of your Cloud Pak for AIOps instance to monitor all the resources and their associated errors and warnings.

- Monitoring with Prometheus and Grafana

  Prometheus can serve as a monitoring system, while Grafana acts as a visualization tool to oversee your current installation. Prometheus and Grafana can be installed and configured on a Red Hat OpenShift Container Platform cluster.

- Monitoring data processed

  Monitor the volume of data that is processed by Cloud Pak for AIOps to see whether the OpenShift Container Platform cluster is sized properly.

Circuit breaker for Kafka robustness and stability

Equip IBM Cloud Pak for AIOps with the ability to protect itself and stay operational during an event storm by implementing a circuit breaker pattern. This helps prevent system failure while ensuring events, alerts, and incidents are still processed.

For more information, see Circuit breaker for Kafka robustness and stability.

Cluster logging

As a cluster administrator, you can deploy centralized logging on an OpenShift Container Platform cluster, and use it to collect and aggregate node system audit logs, application container logs, and infrastructure logs. You can forward logs to your chosen log solution, including on-cluster, and Red Hat managed log storage. You can also visualize your log data in the OpenShift Container Platform web console, the Kibana web console, or 3rd party log aggregator depending on your deployed log storage solution.

Note: The Kibana web console is deprecated.

OpenShift Container Platform cluster administrators can deploy logging by using Operators.

For information, see About logging.

Installation and upgrade health checks

To prepare your cluster for installing or upgrading IBM Cloud Pak for AIOps, and to ensure the health of your deployment afterwards, you can run prerequisite checks and health checks.

Install readiness checks

To help ensure that your cluster is ready to begin an installation of IBM Cloud Pak for AIOps, run the following health check:

- Request that your IBM Sales representative (or Business Partner) uses the IBM Cloud Pak for AIOps custom sizing tool to create a sizing profile to meet your operation workload needs. By having this profile before you begin an installation, you can help to ensure that you have the allocated resources for handling your workload volumes. Contact your IBM Sales representative (or Business Partner) for more information about this tool. For more information about custom sizing, see Hardware requirements - Custom sizing.
- After you prepare your storage and Red Hat OpenShift Container Platform cluster, install and run the IBM Cloud Pak for AIOps prerequisite checker tool. Running this tool verifies whether your Red Hat OpenShift cluster is correctly set up for an IBM Cloud Pak for AIOps installation. For more information about the script, and how to download and run it, see github.com/IBM.

  For more information about running the prerequisite checker during an installation, see:

  - Online production installation of IBM Cloud Pak for AIOps (CLI method)
  - Online production installation of IBM Cloud Pak for AIOps (console method)
  - Online starter installation of IBM Cloud Pak for AIOps (CLI)

Post-installation health check

After you complete your installation of IBM Cloud Pak for AIOps and some time is passed, run the MustGather tool with the **`healthcheck`** option to check the current health of your deployment and Red Hat OpenShift Container Platform cluster.

For more information about installing and running this tool, see:

- Installing the MustGather tool

  Important: Ensure that your installed version of the tool is **`v1.17.6`** or newer. Some healthcheck data is only gathered with version **`v1.17.6`** and newer.

- Running the MustGather tool (healthcheck)

  When running the tool, use the following command:

  ```
  waiops-mustgather.sh -DO healthcheck
  ```

Upgrade readiness checks

To help ensure that your cluster is ready to begin an upgrade of IBM Cloud Pak for AIOps, run the following health check:

- Run the IBM Cloud Pak for AIOps prerequisite checker tool. Running this tool verifies whether your Red Hat OpenShift cluster is correctly set up for upgrading IBM Cloud Pak for AIOps. For more information about the script, and how to download and run it, see github.com/IBM.

  For more information about running the prerequisite checker during an upgrade, see:

  - Online upgrade of IBM Cloud Pak for AIOps (console method)
  - Online upgrade of IBM Cloud Pak for AIOps (CLI method)
  - Offline upgrade of IBM Cloud Pak for AIOps

Post-upgrade health check

- After you complete your upgrade of IBM Cloud Pak for AIOps and some time is passed, run the MustGather tool with the **`healthcheck`** option to check the current health of your deployment and Red Hat OpenShift Container Platform cluster.

For more information about installing and running this tool, see:

- Installing the MustGather tool

Important: Ensure that your installed version of the tool is `v1.17.6` or newer. Some healthcheck data is only gathered with version `v1.17.6` and newer.

- Running the MustGather tool (healthcheck)

  When running the tool, use the following command:

  ```
  waiops-mustgather.sh -DO healthcheck
  ```

Proactive health checks and monitoring

To maintain your system as you complete Day 2 operations, review the following guidance for completing routine health checks and for monitoring the ongoing status and health of your IBM Cloud Pak for AIOps deployment and your Red Hat OpenShift Container Platform cluster.

Monitor Red Hat OpenShift Container Platform

Routinely check the Red Hat OpenShift Container Platform Monitoring dashboards in the web console. Red Hat OpenShift Container Platform includes a preconfigured, preinstalled, and self-updating monitoring stack that provides monitoring for core platform components. Red Hat OpenShift Container Platform also provides a comprehensive set of monitoring dashboards that help you understand the state of cluster components and user-defined workloads.

- Use the Administrator perspective to access the monitoring dashboards to monitor the following components:
  - API performance
  - etcd
  - Kubernetes compute resources
  - Kubernetes network resources
  - Prometheus
  - Cluster and node performance (USE method dashboards)

- Use the Developer perspective to access Kubernetes compute resources dashboards to view application metrics for monitoring the following status:
  - CPU usage
  - Memory usage
  - Bandwidth information
  - Packet rate information

For more information about Red Hat OpenShift Container Platform Monitoring and the monitoring dashboards, see:

- About Red Hat OpenShift Container Platform Monitoring.
- Reviewing monitoring dashboards
- Configure and use the Red Hat OpenShift Container Platform Alerting capabilities to monitor your cluster and identify potential problems. With the web console Alerting UI you can manage alerts, silences, and alerting rules to monitor the health of your cluster. For more information, see Managing alerts.

Monitor IBM Cloud Pak for AIOps

For more information about self-monitoring with alerts, see Self-monitoring with alerts.

Run the MustGather health check

Run the MustGather tool with the `healthcheck` option to check the current health of your deployment and Red Hat OpenShift Container Platform cluster.

For more information about installing and running this tool, see the following topics:

- Installing and running the MustGather tool (Linux)
- Installing the MustGather tool (OpenShift)

  Important: If you are using the (OpenShift) version, ensure that your installed version of the tool is `v1.17.6` or newer. Some healthcheck data is only gathered with version `v1.17.6` and newer.

- Running the MustGather tool (healthcheck)

  When running the tool, use the following command:

  ```
  waiops-mustgather.sh -DO healthcheck
  ```

Reactive health checks and troubleshooting

When you encounter any issues with the health of your IBM Cloud Pak for AIOps deployment or Red Hat OpenShift Container Platform cluster, run a health check with the MustGather tool to gather data to analyze to help you identify problems.

Run the MustGather tool

For more information about installing and running this tool, see:

- Installing the MustGather tool
- Running the MustGather tool (healthcheck)

  When running the tool, use the following command:

  ```
  waiops-mustgather.sh -DO healthcheck
  ```

Keep a copy of the generated logs in case you need to open a support case with IBM Support. As part of opening a case, provide the MustGather logs to IBM Support.

Review known issues and troubleshooting

In addition to running the MustGather health check, review the troubleshooting and known issues for IBM Cloud Pak for AIOps to determine whether your problem is already known and if a solution or workaround is identified.

- Known issues and limitations
- Troubleshooting

Self-monitoring with alerts

You can use Red Hat® OpenShift® Container Platform inbuilt Alertmanager to monitor and send alerts to Cloud Pak for AIOps when a problem occurs in the underlying infrastructure.

Cloud Pak for AIOps can ingest events from multiple sources and carry out analytics on them for you to reduce the noise and focus on the events that matter the most in your network. What if Cloud Pak for AIOps itself or the infrastructure that it is running on has a looming problem that might result in losing your event management system?

Since Cloud Pak for AIOps runs on OpenShift Container Platform, you can use the inbuilt Alertmanager feature of OpenShift Container Platform to do the monitoring and configure it to send alerts to Cloud Pak for AIOps when it sees a problem with any of the underlying infrastructure. Examples of problems include pod restarts, low storage, or latency issues, which can cause the loss of the event management system.

Note: Alertmanager sends you initial warning alerts and then escalates those to Critical as the issue becomes more serious. For example, when storage passes a threshold, you initially get a warning alert, but as the threshold goes to 90% an alert becomes Critical.

Complete the following steps to configure the monitoring by using the Alertmanager:

1. Create a Generic Webhook integration.

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, search **Generic Webhook** and click the tile to set up a new webhook ingestion endpoint.

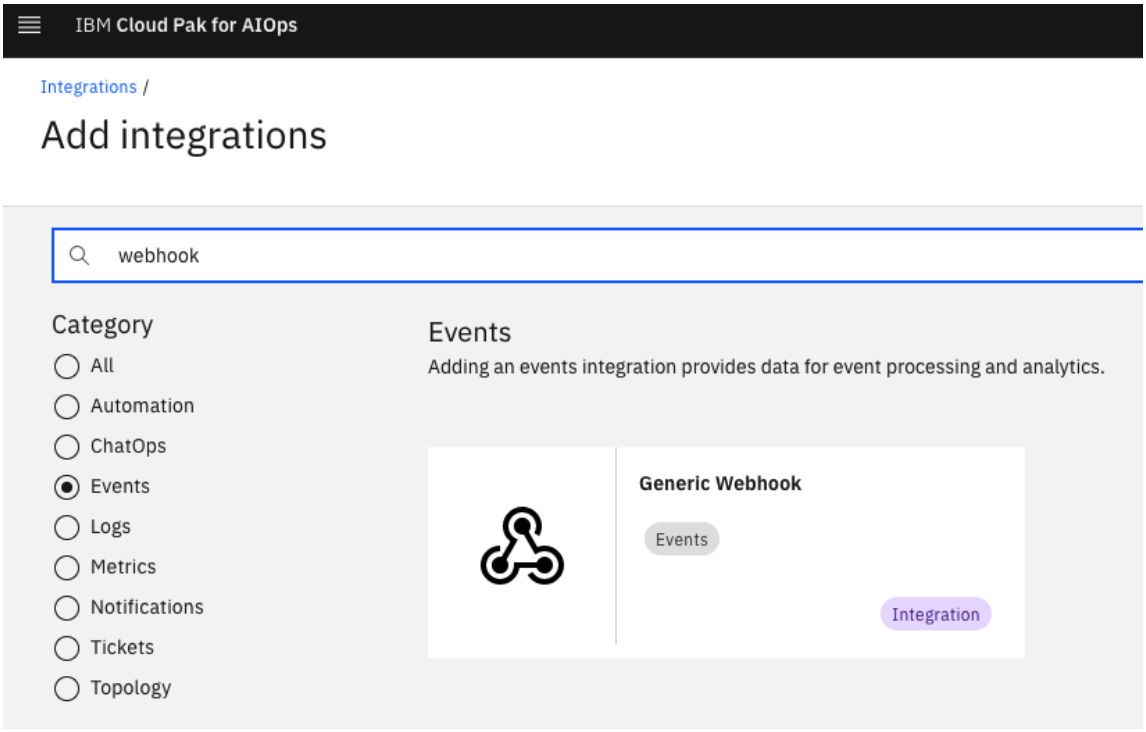

Figure. Generic Webhook integration

5. In the *Add Integration* dialog box, provide a name for the integration and select **None** as the **Authentication type** and click **Next**.

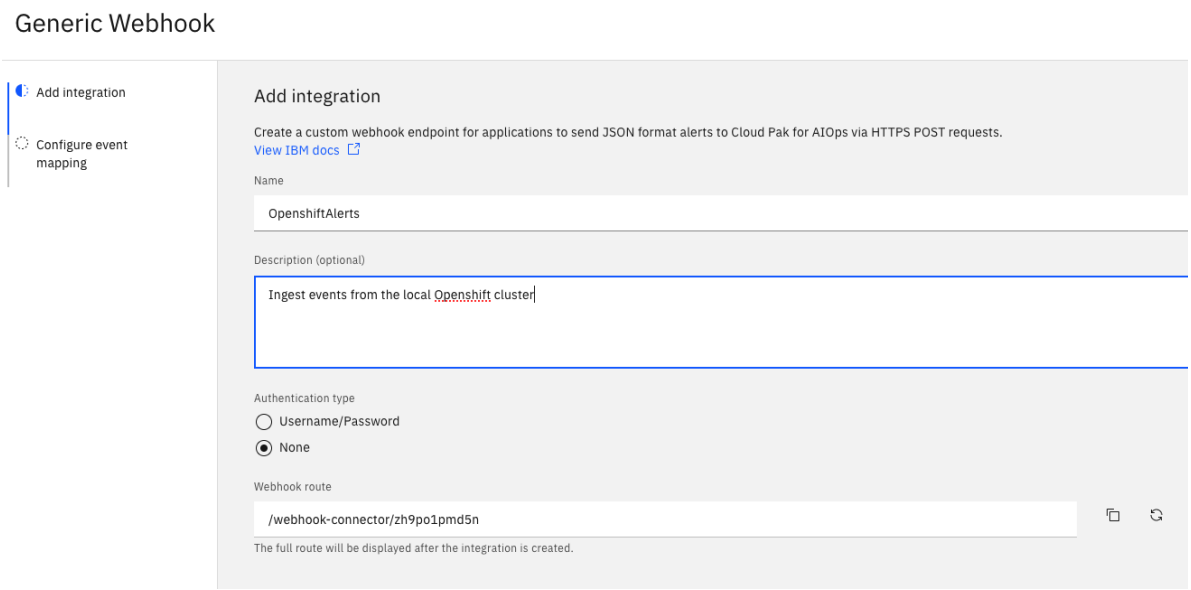

Figure. Add integration page

6. Click **Load sample mapping** and select **Prometheus Alert Manager** to configure the integration with the correct schema mapping from Prometheus to Cloud Pak for AIOps alerts. Click **Done**.

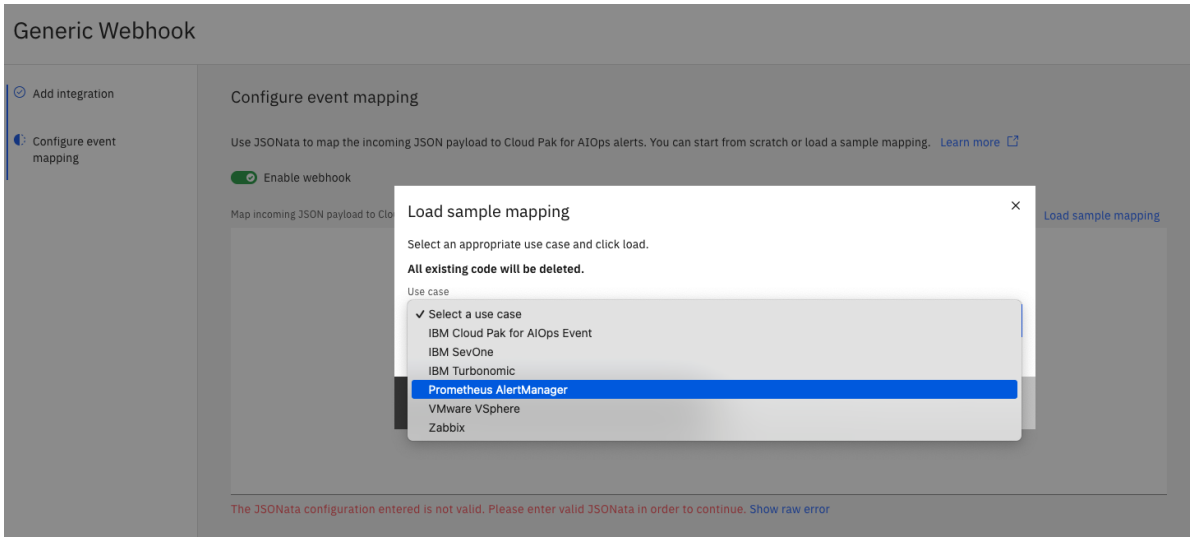

Figure. Configure event mapping

2. Copy the webhook URL to the Red Hat® OpenShift® Alertmanager user interface.

1. From the new Generic Webhook integration that you created, copy the full webhook URL and switch to the OpenShift Container Platform console. An example URL looks like **`https://whconn-6492ea38-cf72-4f3d-b7d3-9fbbc2b1065c-aiops.apps.example.com/webhook-connector/ezca4fgo2tj`**.
2. In the OpenShift Container Platform console go to **Administration** > **Cluster Settings** > **Configuration** > **Alertmanager**.
3. Edit the *Receivers* section for *Critical* and *Default* **Receiver name**.

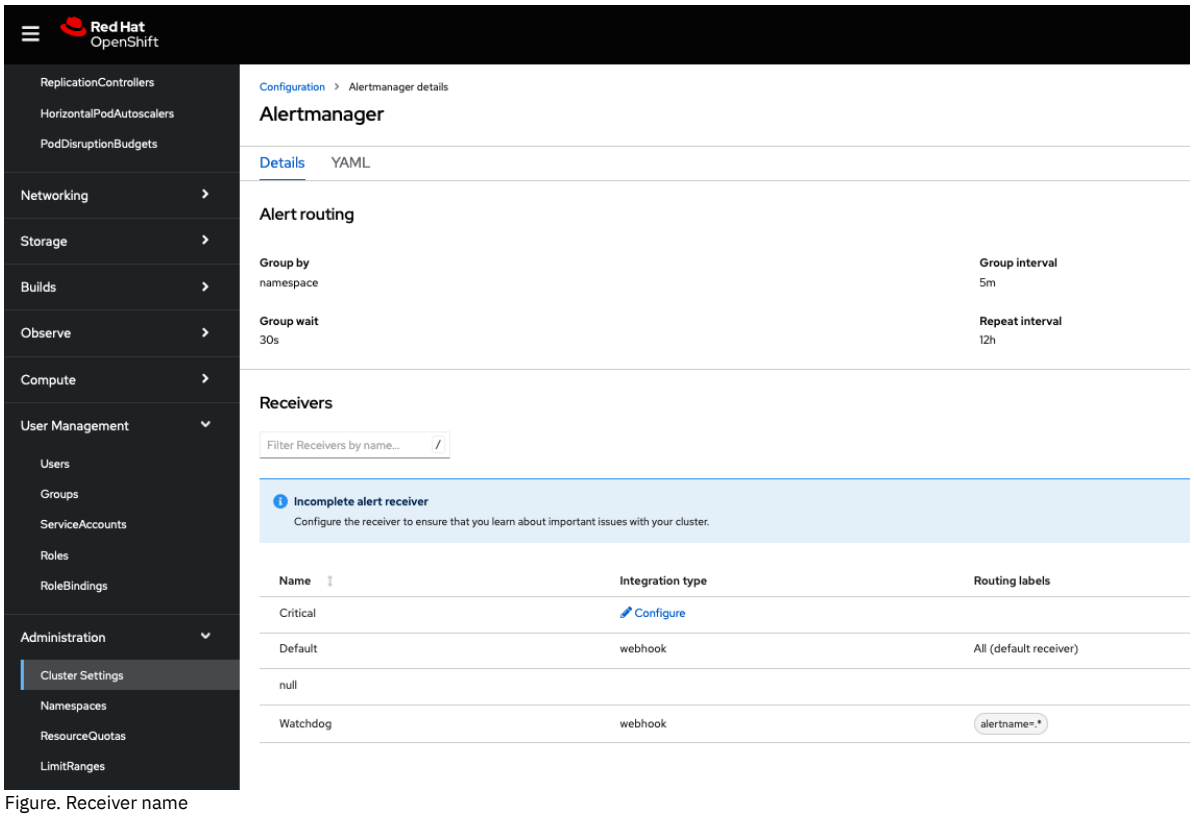

Figure. Receiver name

4. Select **Webhook** for the **Receiver Type** field and paste the full URL into the **URL** field.

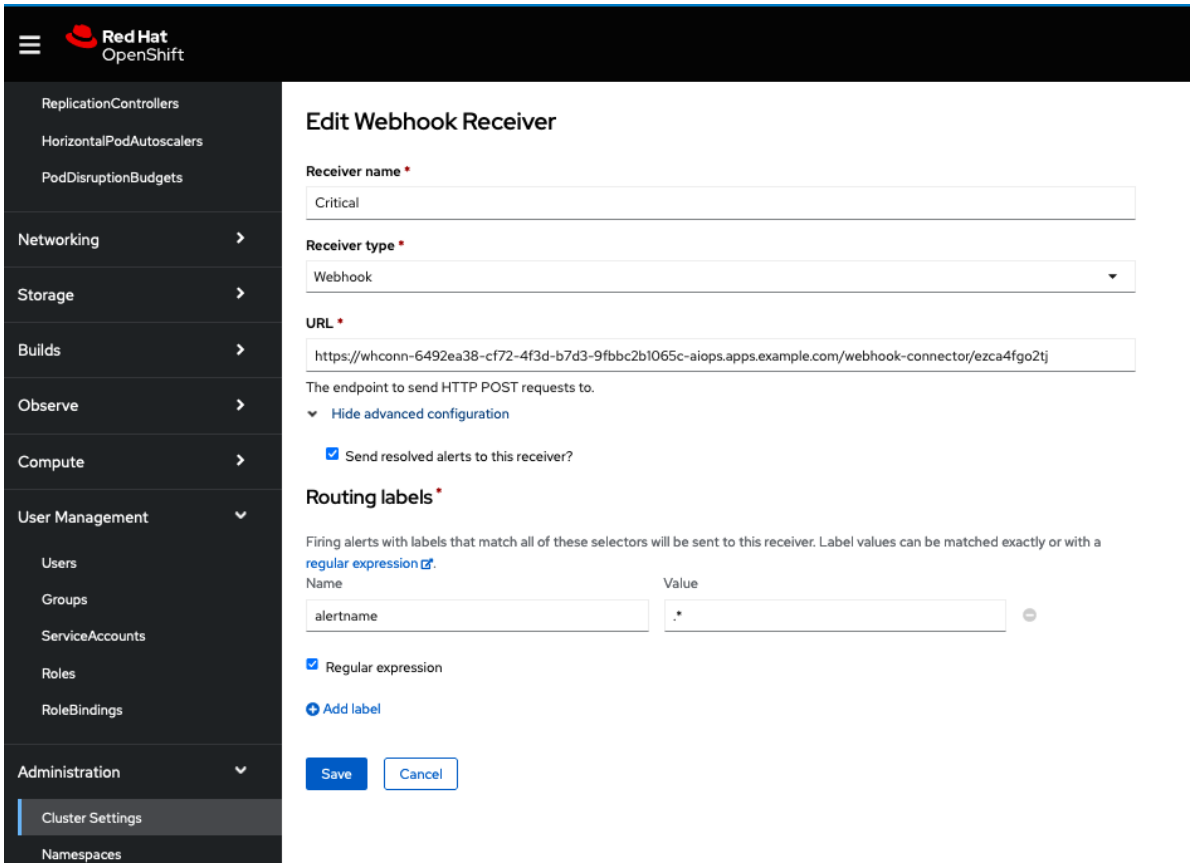

Figure. Webhook receiver

3. Configure Alertmanager to send the alerts you are interested in.

Use the Routing labels section to further filter the alerts that get sent to Cloud Pak for AIOps.

The preceding sample figure (with caption Webhook receiver) sends all alerts by using the value of `.*`.

In the *Routing labels* section of the Webhook receiver, you can use **`alertname`** and a value of `.*` to allow all alerts through, or you can filter by using, for instance, alertname with a value of **SystemMemoryExceedsReservation** or any other regular expression that gives you the set of alerts that you want to manage in Cloud Pak for AIOps. When an OpenShift Container Platform alert is generated it contains *Labels* attached to it as shown in the following example output:

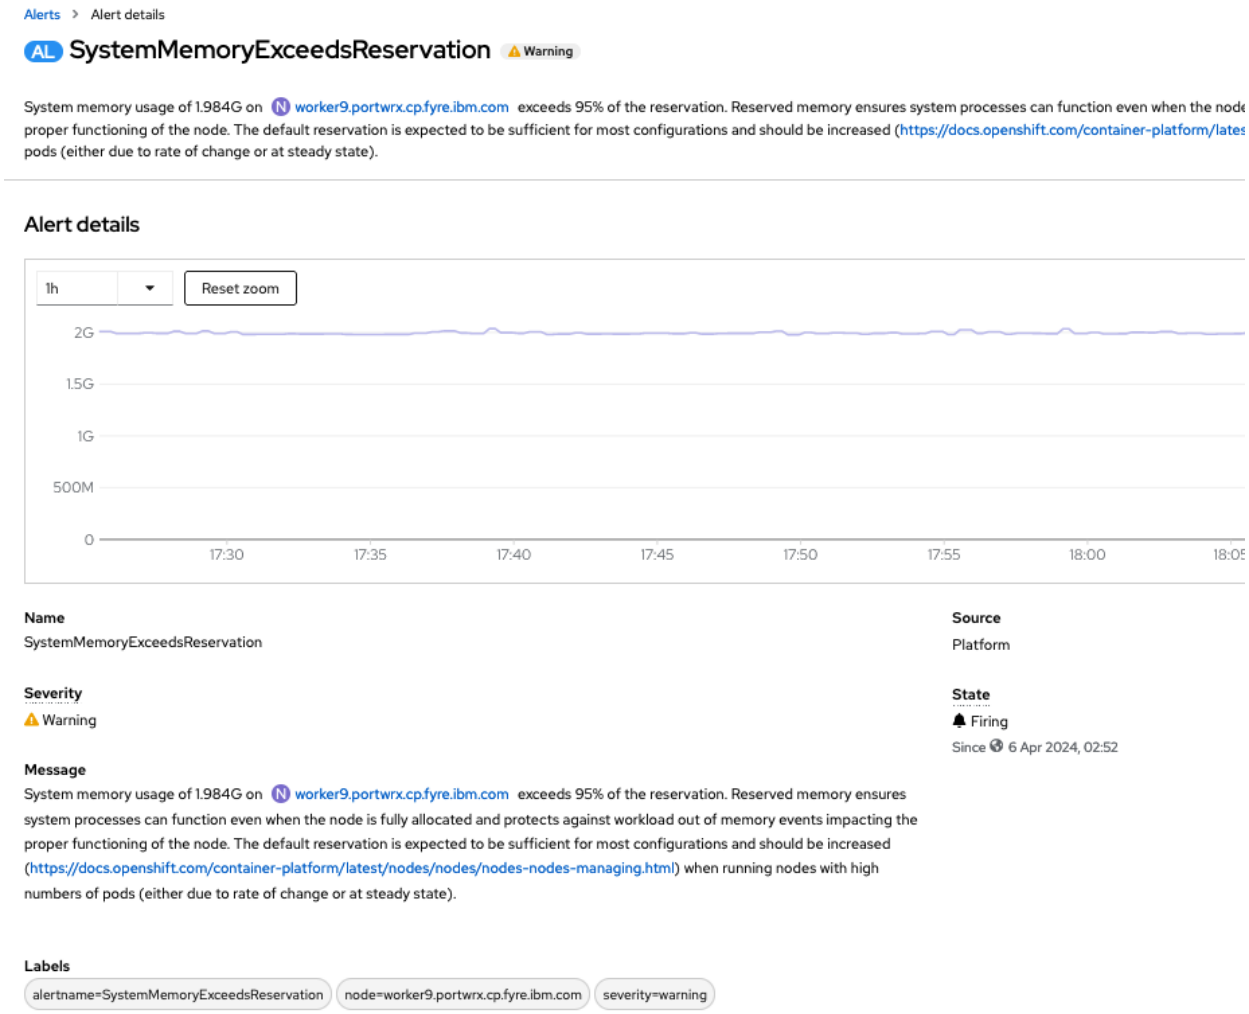

Figure. Labels

When you save the Alertmanager configuration, any existing active alerts appear in your Alert Viewer.

Optionally, you can also create an Cloud Pak for AIOps policy to scope group these Prometheus based alerts if you want those to be grouped in one Cloud Pak for AIOps incident.

The following simple example policy provides a scope-based grouping:

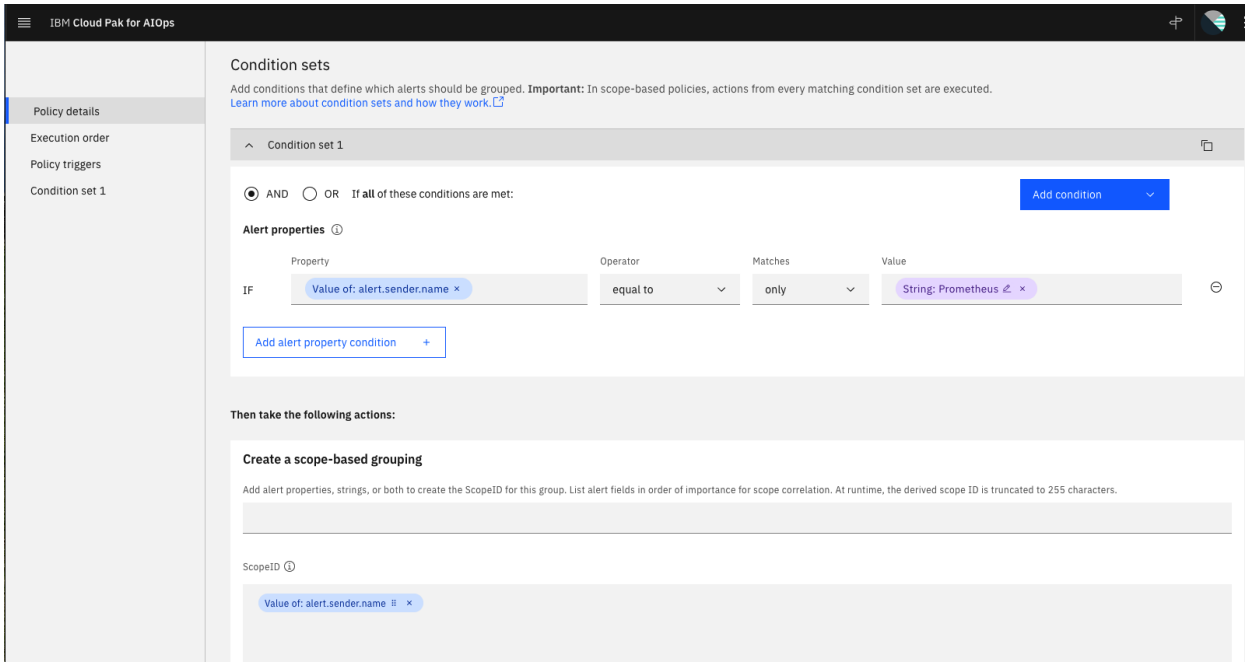

Figure. Scope-based grouping

Note: Alertmanager requires a trusted webhook endpoint. If your Cloud Pak for AIOps deployment is not using certs that are trusted by OpenShift itself, it cannot send the alerts to Cloud Pak for AIOps. You need to use trusted certs or add the Cloud Pak for AIOps CA signing cert to the OpenShift CA bundle. For more information about certs, see Updating the CA bundle.

Self-monitoring with topology

You can create the topology visualization of your Cloud Pak for AIOps instance to monitor the errors and warnings and to view all the resources, which make up the Cloud Pak for AIOps installation.

With the topology, see how different aspects of the estate are related to one another. Also, use it for more advanced analytics, such as topology-based alert correlation, probable cause determination, inventory management, and more.

Since Cloud Pak for AIOps runs on Red Hat OpenShift Container Platform, you need a single observer to get started, namely the *Kubernetes observer*. The Kubernetes observer works with many of the Kubernetes-based platforms, such as Red Hat OpenShift and Google Kubernetes Engine.

To configure a Kubernetes integration, you need the following information:

- Kubernetes cluster or data center name
- Namespace where Cloud Pak for AIOps is installed
- Kubernetes master IP address
- Kubernetes API port
- Kubernetes token

Complete the following steps to configure the self-monitoring by using the Kubernetes integration:

1. Create and use a Service Account.

To create and use a Service Account, follow the steps that are listed under the topic Kubernetes Observer Load job prerequisites.

2. Configure the observer.

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars). Then, click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, search **Kubernetes** and click the **Kubernetes** tile.
5. Click **Get started**.
6. Select **Load** as **job type**.
7. Enter the values for the **Unique ID**, **data_center**, **Kubernetes Master IP Address**, **Kubernetes API port**, and **Kubernetes token** fields.

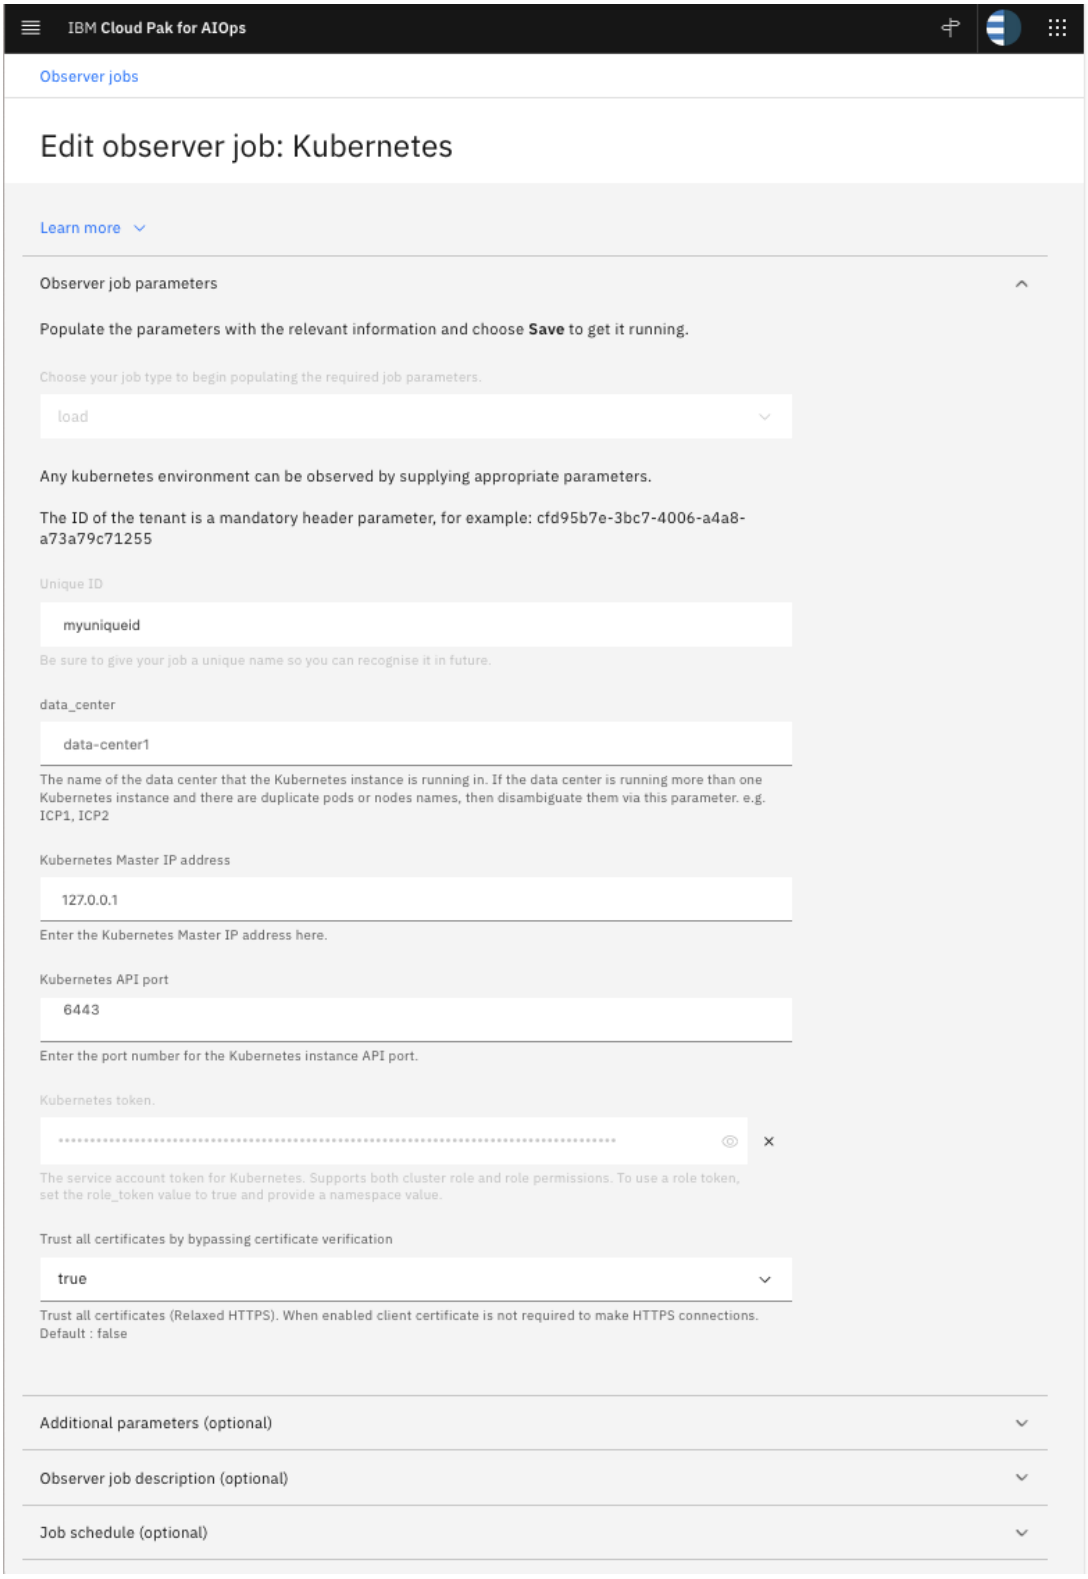

Figure. Kubernetes observer job

8. Under the *additional parameters (optional)* tab, enter the namespace where Cloud Pak for AIOps is installed so you observe only the namespace and not the other applications installed on the cluster.

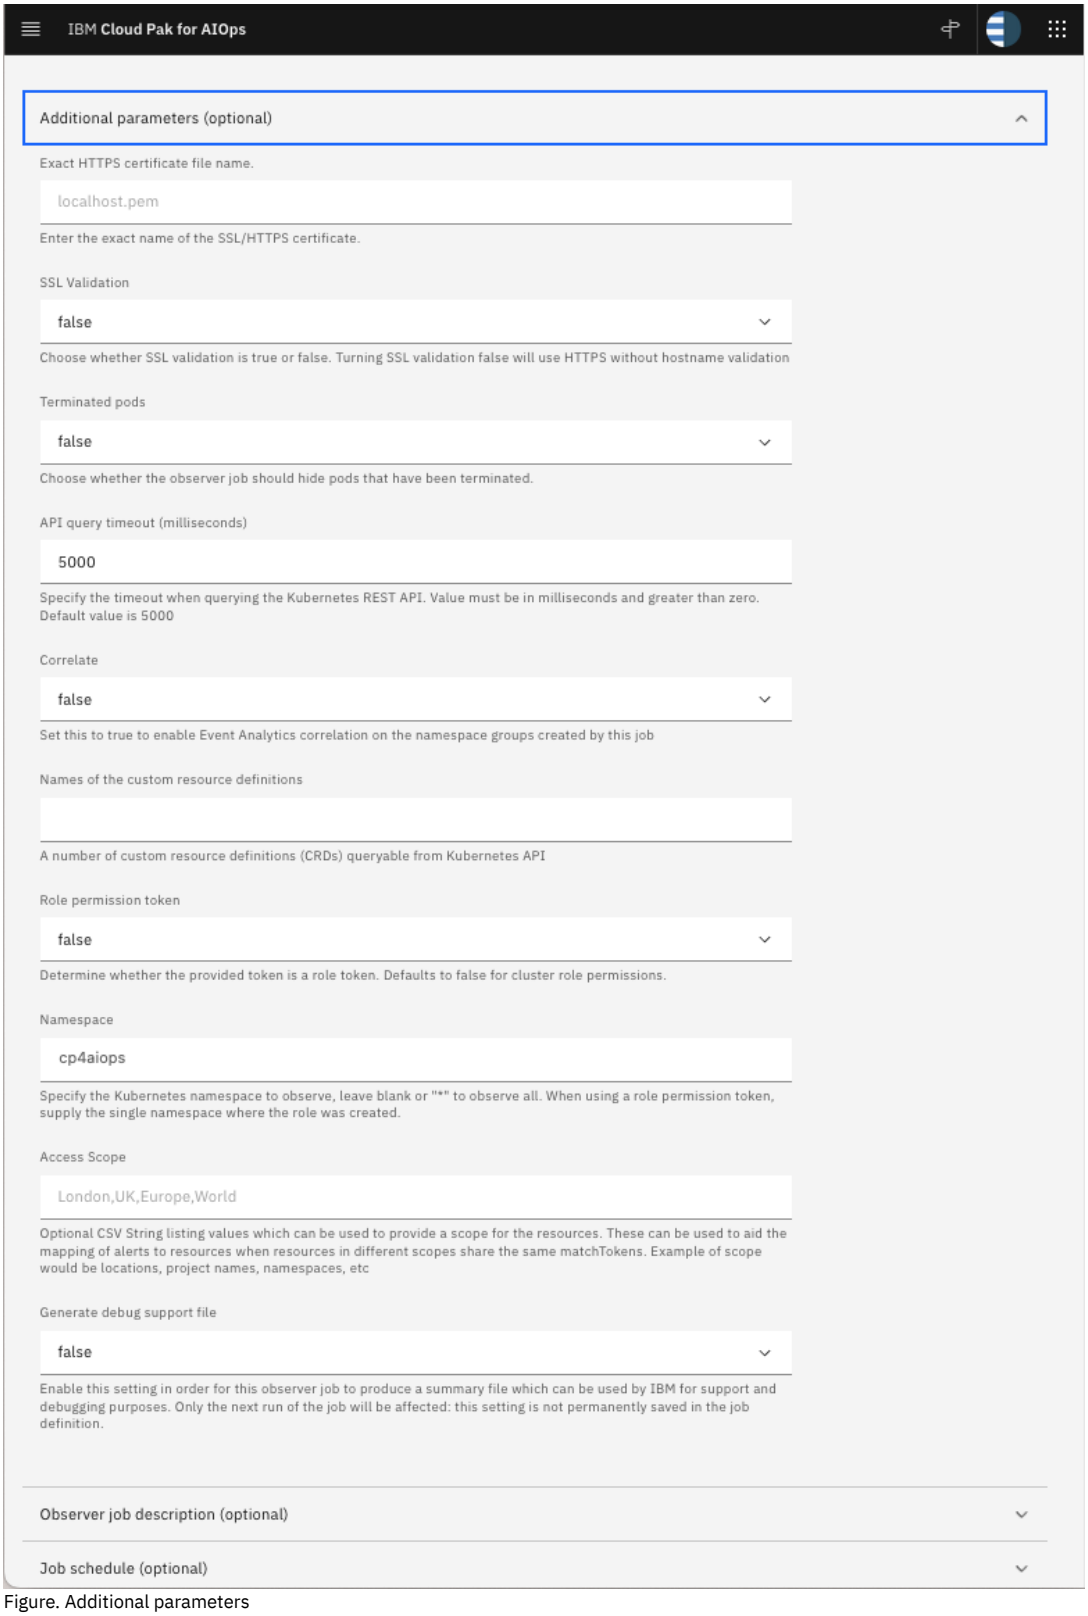

Figure. Additional parameters

9. Under the *Job schedule (optional)* tab, indicate how frequently you want to refresh the information. For example, refresh every 5 minutes.

For more information about all the fields, see Configuring Kubernetes Observer jobs.

3. View the topology.

When the observer job runs for the first time, it creates a resource group by using the name that is provided in the observer **data_center** field.

The observer brings in the alerts, errors, and warnings, which are displayed under the *Resource groups* tab.

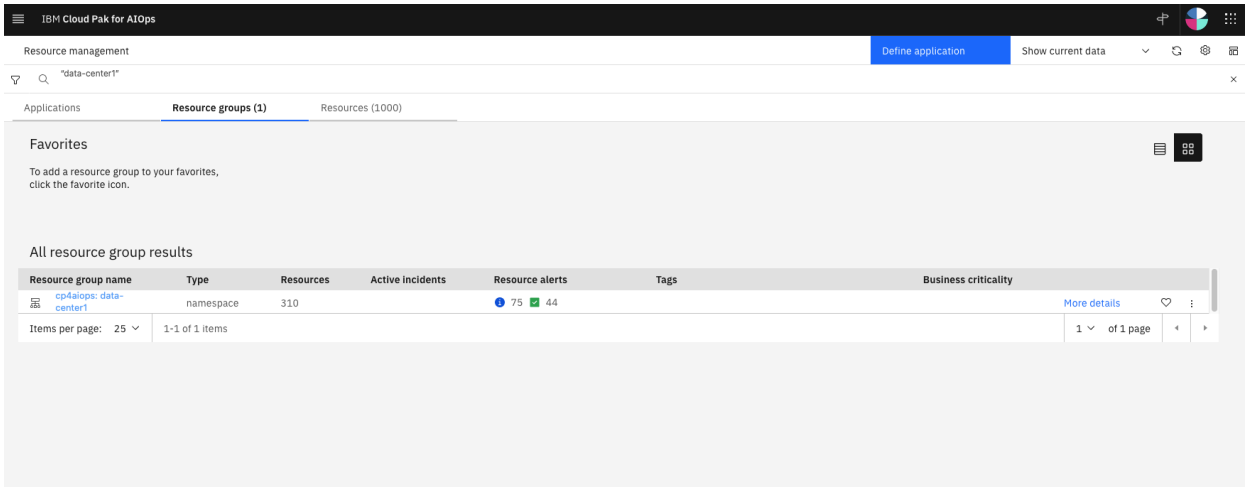

Figure. Resource group results

When you click the resource group name that is created by the observer job, you can view all the resources, which make up the Cloud Pak for AIOps installation. If the cluster is updated, or the Cloud Pak for AIOps is updated, the changes are shown as displayed in the following example.

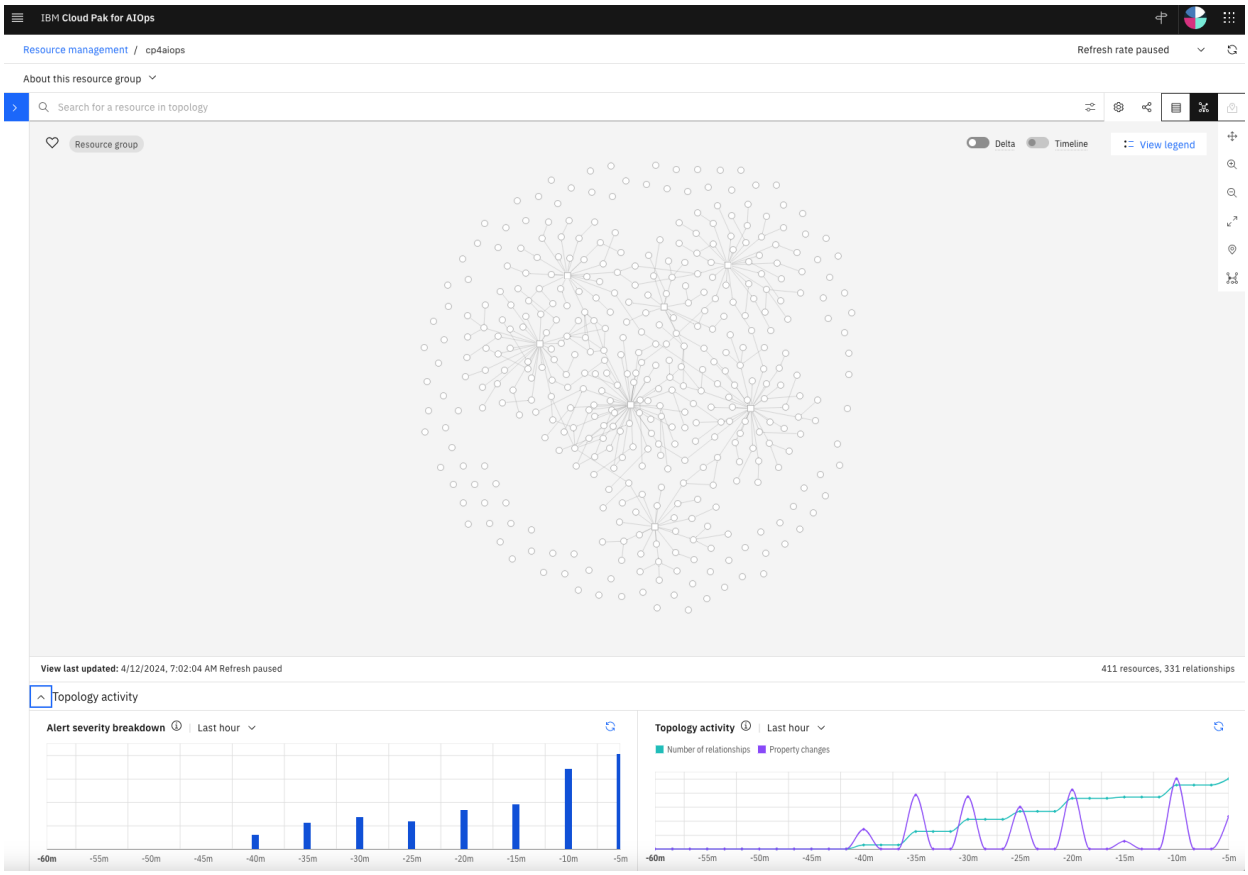

Figure. Resource group in Resource management

4. Create topology resource groups.

The view of the entire set of resources for Cloud Pak for AIOps is useful, but it might be useful to look at specific portions. For example, you can view each node to see the workload of the node and any issues associated with that node.

To create groups for each of the nodes, you can use the dynamic resource group template. For more information, see Building resource group templates.

Use the following steps to create topology resource groups:

1. From the main navigation of the Cloud Pak for AIOps console, click **Resource management**.
2. Click **Resource group templates** icon.
3. Click **Create a new template** > **Dynamic template**.
4. Click **Start**. The Template builder page appears.

5. In the search box, enter the resource name, for example, **`worker1.data-center1.example.com`**, and click the desired resource.

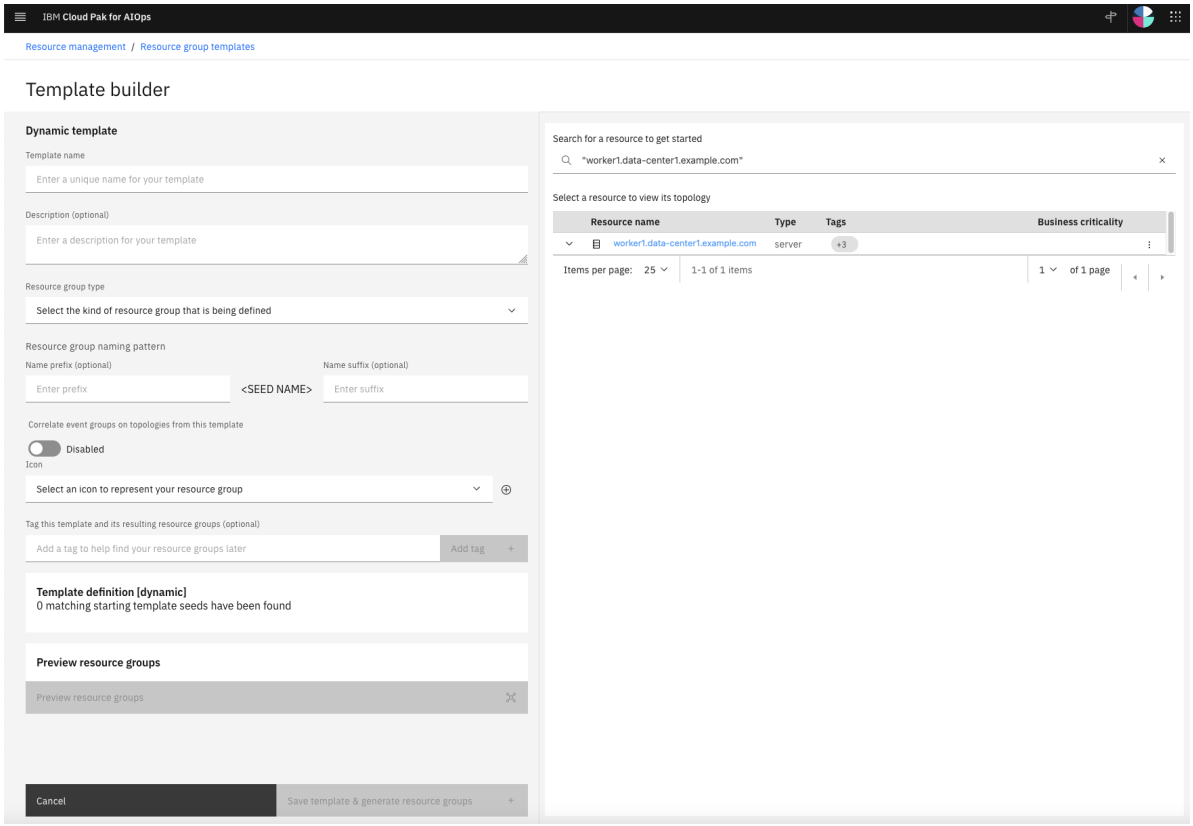

Figure. Template builder

6. To see both the node and the associated workload, right-click the large node image as shown in the following example, and select **Get Neighbors**.

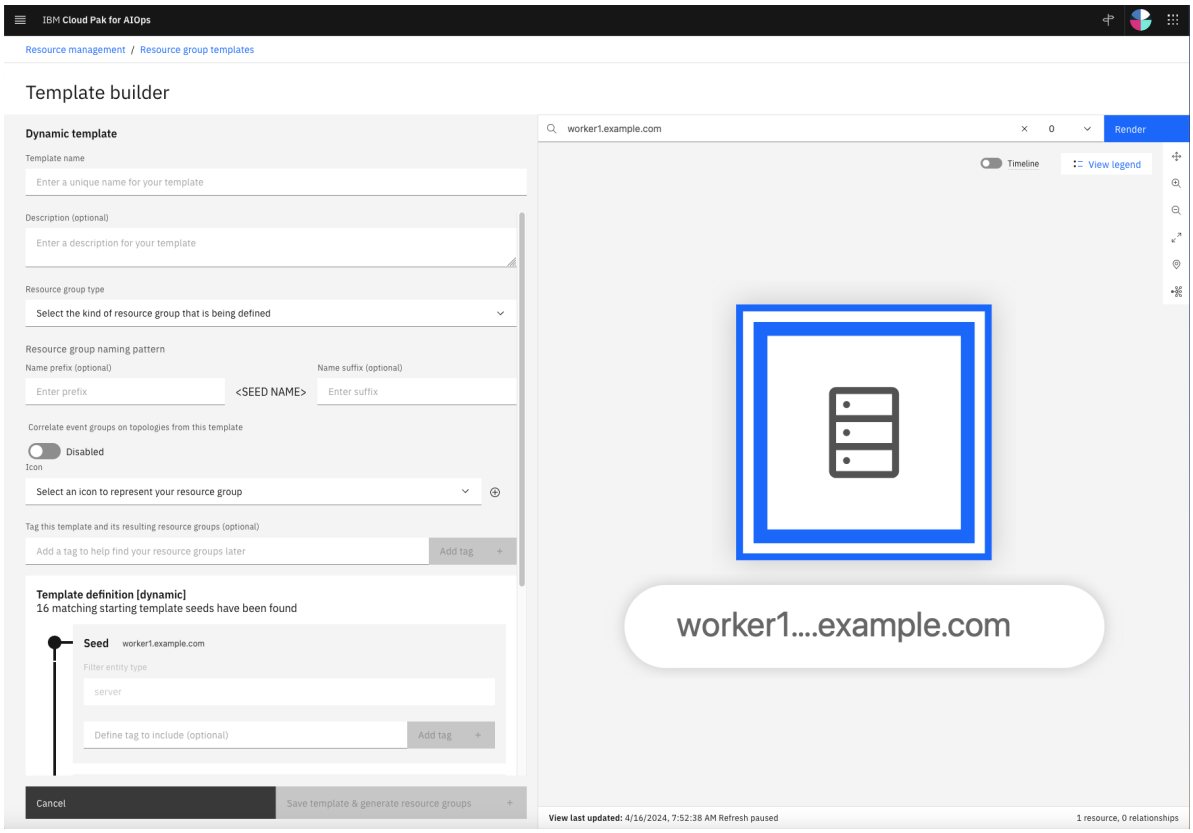

Figure. Render template

When you hover over the large node image, you see the full name of the resource and the type of the resource.

7. Click **All**. This option shows the pods that are running on the node and the information such as the IP address.

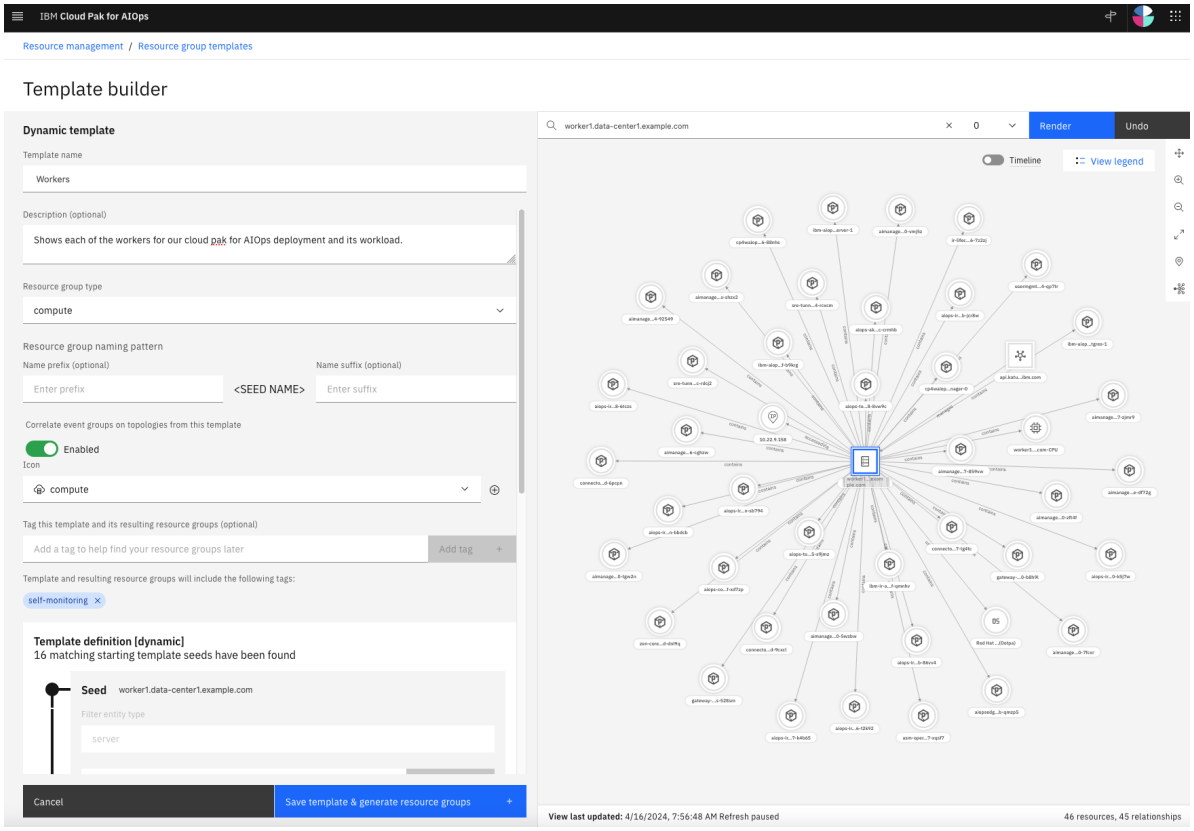

Figure. Workload of node

8. Provide a Template name and description.
9. Select the resource group type. For example, **compute**.
10. Optionally, add a tag name. For example, **self-monitoring**. Adding a tag helps with the filtering of results that are listed under the resource groups.
11. Click **Save template & generate resource groups**.

Cloud Pak for AIOps creates the template and automatically creates the resource groups for all the nodes, each showing the workload as seen from the following example.

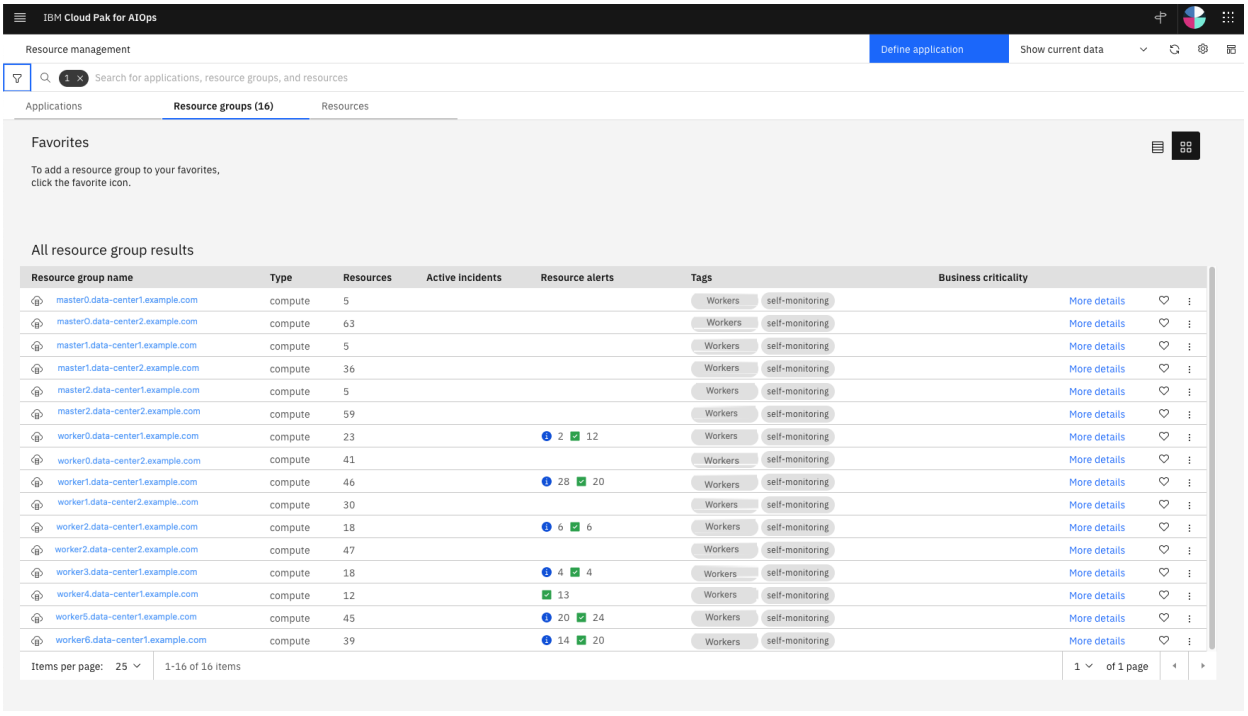

Figure. Resource group results

Monitoring with Prometheus and Grafana

You can use Prometheus as a monitoring system and Grafana as a visualization tool to monitor your existing installation of IBM Cloud Pak for AIOps. Prometheus and Grafana can be installed and configured on a Red Hat OpenShift Container Platform cluster.

Prometheus is an open-source toolkit that can be used with Grafana to create real-time dashboards for monitoring Cloud Pak for AIOps stability and performance.

Note: The following instructions are updated to support the Grafana v5 operator, which is compatible with OpenShift version 4.11.x or higher. Previously, these instructions used the Grafana v4 operator, which is not supported by OpenShift version 4.16.x or higher. If you followed the instructions for the Grafana v4 operator, there might be compatibility issues if you upgrade your OpenShift version to 4.16.x or higher. To check your version of the Grafana operator, go to your OpenShift console, **Operators** > **Installed Operators**. To upgrade your Grafana operator from v4 to v5, run the cleanup script, and follow the instructions detailed in the Viewing metrics in Grafana section.

Warning: The clean up script deletes any existing dashboards in Grafana. Copy the JSON of any existing dashboards that you want to keep.

Clean up script (optional):

```
oc project monitoring grafana
# delete CRs
oc delete grafana grafana
oc delete grafanadatasource prometheus

# delete subscription & CSV
CSV=$(oc get subscription monitoring-grafana -o json | jq -r '.status.installedCSV')
oc delete subscription monitoring-grafana
oc delete csv $CSV

# delete CRDs
# IMPORTANT: if you created any additional CRD instances, make sure to delete them before deleting the definition
oc delete crd grafanadashboards.integreatly.org
oc delete crd grafanadatasources.integreatly.org
oc delete crd grafanafolders.integreatly.org
oc delete crd grafananotificationchannels.integreatly.org
oc delete crd grafanas.integreatly.org

# delete the rest of v4 associated resources
oc delete clusterrole grafana-proxy
oc delete rolebinding grafana-proxy
oc delete secret grafana-k8s-proxy
```

Notes:

- The monitoring stack that is described in the following sections uses 3rd party components that are not owned by IBM, use with caution.
- The monitoring stack that is described in the following sections currently works with Cloud Pak for AIOps that is installed in OpenShift Container Platform cluster. Cloud Pak for AIOps installed in an air-gapped environment (offline) is not supported by the described monitoring stack.

Prerequisites

- You need network connectivity to the OpenShift Container Platform cluster where Cloud Pak for AIOps is installed.
- OpenShift command-line interface is required. For more information, see Getting started with the OpenShift CLI.
- You need to install jq for your operating system to run the commands for JSON processing. For more information, see Download jq.

Use the following sections to set up the monitoring for your Cloud Pak for AIOps environment:

- Setting up user workload monitoring
- Enabling additional metrics
- Viewing metrics in Grafana
- Importing dashboards

Setting up user workload monitoring

OpenShift Container Platform comes with a prometheus-based monitoring stack to track metrics about the cluster. You can extend the monitoring to user workloads by enabling user workload monitoring. User workloads include anything that is not a core OpenShift Container Platform service. For more information about user workloads monitoring and advanced configuration, see User workload monitoring.

To set up the user workload monitoring capability, you need to enable it.

Note: Once you run the following commands, the associated ConfigMaps (configuration settings) are applied cluster-wide. Do not run the commands on a shared cluster that includes applications other than Cloud Pak for AIOps.

Log in to your OpenShift Container Platform cluster by using the command line. Run the following commands to enable the user workload monitoring capability:

```
oc create -n openshift-monitoring -f - <<EOF || true
apiVersion: v1
kind: ConfigMap
metadata:
  labels:
    app.kubernetes.io/created-by: IBM
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
```

```
    enableUserWorkload: true
EOF

oc create -n openshift-user-workload-monitoring -f - <<EOF || true
apiVersion: v1
kind: ConfigMap
metadata:
  labels:
    app.kubernetes.io/created-by: IBM
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
EOF
```

After you run the preceding commands, you can view metrics in OpenShift Container Platform web console.

Viewing metrics in OpenShift Container Platform cluster

To view the metrics, go to **Observe** > **Metrics** in OpenShift Container Platform web console. You can enter a valid Prometheus query and graph the result. The following are some example queries that you can use to view the metrics for your Cloud Pak for AIOps environment:

1. The total number of pods that are in a running state across all namespaces:

   ```
   sum(kube_pod_status_phase{namespace=~".*", phase="Running"})
   ```

2. The total amount of memory that is allocated across all the nodes:

   ```
   sum (machine_memory_bytes{node=~"^.*$"})
   ```

3. Deployment replicas across all the namespaces:

   ```
   kube_deployment_status_replicas{namespace=~".*"}
   ```

Enabling additional metrics

In some cases you might need configuration to enable additional metrics for your Cloud Pak for AIOps environment.

Kafka

Since a large portion of communication within Cloud Pak for AIOps takes place in Kafka, it is highly beneficial to acquire metrics from Kafka.

Notes:

- Kafka metrics, such as those displayed in the usage dashboard, are only available from the moment the metrics are enabled. Viewing time windows that precede the enabling of the metrics results in nothing being displayed.
- The Kafka custom resource (CR) must be in a ready state for metric scraping to be enabled successfully. To view the status of the Kafka CR, navigate to **Home** > **Search**. Search for the **Kafka resource** and click on **Kafka instance**. The **Conditions** section at the end of the page shows the `Status`.

Use the following steps to enable Kafka metrics:

1. Switch to the project (namespace) where Cloud Pak for AIOps is installed:

   ```
   oc project <namespace>
   ```

   Where `<namespace>` is the project (namespace) where Cloud Pak for AIOps is installed

2. Define the Kafka `ConfigMap` and `PodMonitor` resources to configure the Kafka Prometheus exporter:

   1. Define the Kafka `ConfigMap` resource:

      ```
      KAFKA_METRICS_CONFIGMAP='
      kind: ConfigMap
      apiVersion: v1
      metadata:
        name: kafka-metrics
        labels:
          app: strimzi
      data:
        kafka-metrics-config.yml: |
          # See https://github.com/prometheus/jmx_exporter for more info about JMX Prometheus Exporter metrics
          lowercaseOutputName: true
          rules:
          # Special cases and very specific rules
          - pattern: kafka.server<type=(.+), name=(.+), clientId=(.+), topic=(.+), partition=(.*)><>Value
            name: kafka_server_$1_$2
            type: GAUGE
            labels:
             clientId: "$3"
             topic: "$4"

      type: GAUGE
      labels:
        replicaId: "$2"
        memberType: "$3"
'
```

2. Define the **PodMonitor** resource:

```
KAFKA_PODMONITOR='
apiVersion: monitoring.coreos.com/v1
kind: PodMonitor
metadata:
  name: kafka-resources-metrics
  labels:
    app: strimzi
spec:
  selector:
    matchExpressions:
      - key: "ibmevents.ibm.com/kind"
        operator: In
        values: ["Kafka", "KafkaConnect", "KafkaMirrorMaker", "KafkaMirrorMaker2"]
  namespaceSelector:
    matchNames:
      - myproject
  podMetricsEndpoints:
  - path: /metrics
    port: tcp-prometheus
    relabelings:
    - separator: ;
      regex: __meta_kubernetes_pod_label_(ibmevents_ibm_com_.+)
      replacement: $1
      action: labelmap
    - sourceLabels: [__meta_kubernetes_namespace]
      separator: ;
      regex: (.*)
      targetLabel: namespace
      replacement: $1
      action: replace
    - sourceLabels: [__meta_kubernetes_pod_name]
      separator: ;
      regex: (.*)
      targetLabel: kubernetes_pod_name
      replacement: $1
      action: replace
    - sourceLabels: [__meta_kubernetes_pod_node_name]
      separator: ;
      regex: (.*)
```

```
      targetLabel: node_name
      replacement: $1
      action: replace
    - sourceLabels: [__meta_kubernetes_pod_host_ip]
      separator: ;
      regex: (.*)
      targetLabel: node_ip
      replacement: $1
      action: replace
'
```

3. Create the **ConfigMap** and **PodMonitor** resources by using the apply command:

```
oc apply -f - <<EOF
${KAFKA_METRICS_CONFIGMAP}
---
${KAFKA_PODMONITOR}
EOF
```

4. Enable the Prometheus JMX exporter by patching the Kafka instance with the **ConfigMap** that you created in the preceding step.

   Note: When you run the following commands, the Kafka brokers perform a rolling restart to enable the metric exporter.

```
oc patch kafka iaf-system --type=merge -p '{
  "spec": {
    "kafka": {
      "metricsConfig": {
        "type": "jmxPrometheusExporter",
        "valueFrom": {
          "configMapKeyRef": {
            "key": "kafka-metrics-config.yml",
            "name": "kafka-metrics"
          }
        }
      }
    }
  }
}'
```

You can now explore the Kafka broker metrics in your cluster.

For more information about Kafka Prometheus Exporter, see Kafka Prometheus Exporter.

To view the metrics, go to **Observe** > **Metrics** in OpenShift Container Platform web console. You can enter a valid Prometheus query and graph the result. For example, you can the use the following Prometheus query to get the active count of all the Kafka topic partitions including the replicas.

```
sum(kafka_server_replicamanager_partitioncount)
```

Viewing metrics in Grafana

You can use Grafana to visualize metrics and logs that come from multiple sources, which include Prometheus and other monitoring tools. Grafana provides a web-based interface for creating and customizing dashboards, which can be used to display various metrics and logs from different sources. You need to install Grafana in your OpenShift Container Platform cluster and configure it to connect to Thanos. For more information about Thanos, see Thanos.

Grafana gives access to all metrics across all of the Prometheus instances (both cluster and user workload metrics). You can use the following commands to install the Grafana v5 operator, set up a Grafana instance, and connect Prometheus as a Grafana data source.

1. Run the following script.

```
oc apply -f - <<EOF
apiVersion: v1
kind: Namespace
metadata:
  name: monitoring-grafana
---
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: operatorgroup
  namespace: monitoring-grafana
spec:
  targetNamespaces:
  - monitoring-grafana
---
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: monitoring-grafana
  namespace: monitoring-grafana
spec:
  channel: v5
  installPlanApproval: Automatic
  name: grafana-operator
  source: community-operators
  sourceNamespace: openshift-marketplace
EOF

oc project monitoring-grafana

# wait for the Grafana operator to finish installing
```

```
installReady=false
while [ "$installReady" != true ]
do
    installPlan=`oc get subscription.operators.coreos.com monitoring-grafana -n monitoring-grafana -o json | jq -r
.status.installplan.name`
    if [ -z "$installPlan" ]
    then
        installReady=false
    else
        installReady=`oc get installplan -n monitoring-grafana "$installPlan" -o json | jq -r '.status|.phase ==
"Complete"'`
    fi

    if [ "$installReady" != true ]
    then
        sleep 5
    fi
done
installReady=false
while [ "$installReady" != true ]
do
    csv=`oc get subscription.operators.coreos.com monitoring-grafana -n monitoring-grafana -o json | jq -r
.status.currentCSV`
    if [ -z "$csv" ]
    then
        installReady=false
    else
        installReady=`oc get csv -n monitoring-grafana "$csv" -o json | jq -r '.status.phase == "Succeeded"'`
    fi

    if [ "$installReady" != true ]
    then
        sleep 5
    fi
done

# set up PVC for persisting dashboards (optional)

```

You might see the following error while the Grafana operator is in the process of deploying:

```
Error from server (NotFound): installplans.operators.coreos.com "null" not found
```

Importing dashboards

Dashboards can be imported into Grafana either by an ID or by importing the dashboard JSON itself.

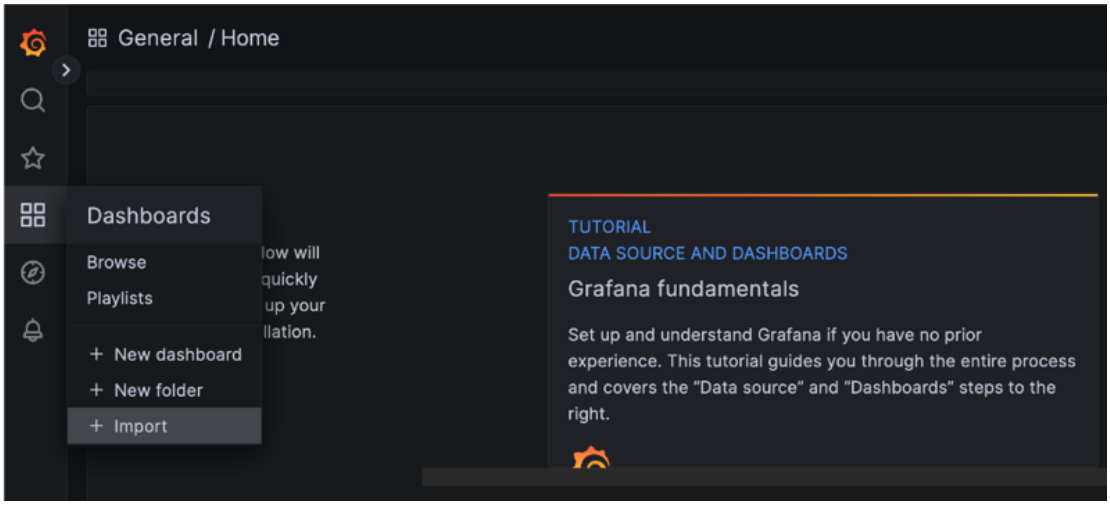

Figure. Grafana monitoring homepage

Importing Cloud Pak for AIOps dashboards to Grafana

Several dashboards are provided to assist in the operational monitoring of Cloud Pak for AIOps.

For more information about how to import a dashboard in Grafana, see Import dashboards.

Cloud Pak for AIOps offers the following custom dashboards available as JSON, which can be uploaded or copy pasted into Grafana. For more information, see the following sections:

- Cloud Pak for AIOps health dashboard
- Cloud Pak for AIOps usage dashboard

Importing other dashboards to Grafana

You can import the following dashboards in Grafana. These dashboards are developed by Grafana community members and can be imported with their ID field.

- **`K8 Cluster Detail Dashboard`** ID 10856
- **`kubernetes-networking-cluster`** ID 16371

Viewing available metrics

The preceding dashboards show a fraction of the metrics that are made available by Prometheus. To view the list of available metrics in your OpenShift Container Platform cluster, run the following commands as described in the Authentication with Bearer token.

1. Obtain the API URL for Thanos querier:

   ```
   oc get routes -n openshift-monitoring thanos-querier -o jsonpath='{.status.ingress[0].host}'
   ```

2. Retrieve the list of available Metric APIs and store the result in **`metrics.json`**:

   Note: The following command might not work on Federal Information Processing Standards (FIPS) enabled clusters due to networking reasons. To get around this issue, log in to OpenShift Container Platform online console and go to any pod. Exec into the pod and run the following command. Alternatively you can log in to the OpenShift Container Platform cluster by using the command line, exec into the pod, and then run the following command.

   ```
   curl -k -H "Authorization: Bearer $(oc whoami -t)" https://<thanos_querier_route>/api/v1/metadata > metrics.json
   ```

   Where **`<thanos_querier_route>`** is the route that you obtained in the preceding command.

All of the Metric APIs listed under the output of the preceding command can be copy and pasted in the cluster under **Observe** > **Metrics**. These queries can be used in Grafana to create new panels. The new panels can be saved in a new dashboard or in one of the existing custom (community) dashboards.

Cloud Pak for AIOps health dashboard

This dashboard focuses on the high level health of Cloud Pak for AIOps, its storage and the cluster that it is running on. This dashboard answers the following questions:

1. Does the cluster have enough resources?
2. How much storage is used?
3. Is the Cloud Pak for AIOps instance healthy?

To import this JSON dashboard, see Importing dashboard by using JSON.

You can import the following JSON into Grafana.

```
{
  "__inputs": [
    {
      "name": "DS_PROMETHEUS",
```

```
      "label": "prometheus",
      "description": "",
      "type": "datasource",
      "pluginId": "prometheus",
      "pluginName": "Prometheus"
    }
  ],
  "__elements": {},
  "__requires": [
    {

Cloud Pak for AIOps usage dashboard

This dashboard focuses on providing visibility into the traffic that flows through your environment and validates that Cloud Pak for AIOps is correctly configured to handle the traffic as described in Custom sizing.

To import this JSON dashboard, see Importing dashboard by using JSON.

You can import the following JSON into Grafana.

```
{
  "__inputs": [

Monitoring data processed

View the volume of data that is processed by Cloud Pak for AIOps to see whether the OpenShift Container Platform cluster is sized properly.

Use the following topics to view the volume of data that is processed by Cloud Pak for AIOps.

Events

For a rough estimate of the number of events, go to the AIOps Insights dashboard. The AIOps Insights dashboard can be accessed from the administration page of IBM Cloud Pak for AIOps, under **Overview** > **Quick navigation** > **AIOps insights**. Alternatively, click the navigation icon (four horizontal bars) to go to the main navigation menu. Then, click **Operate** > **AIOps insights**.

The noise reduction graph shows the number of events over the selected time period, such as 24 hours, 7 days, or 30 days. You can use the average of the events when you use the Cloud Pak for AIOps deployment sizing.

Figure. AIOps Insights dashboard

For more information about precise distribution of events, see Enabling monitoring for user-defined projects.

When the OpenShift user workload monitoring is enabled, you can view the metrics in the OpenShift dashboard.

The following Prometheus query can be used to view the number of events, which can be added in the Cloud Pak for AIOps console console under **Observe** > **Metrics**:

```
sum(irate((flink_taskmanager_job_task_operator_KafkaSourceReader_topic_partition_currentOffset{topic="cp4waiops_cartridge_lifecycle_input_events"}>0)[1m:30s]))
```

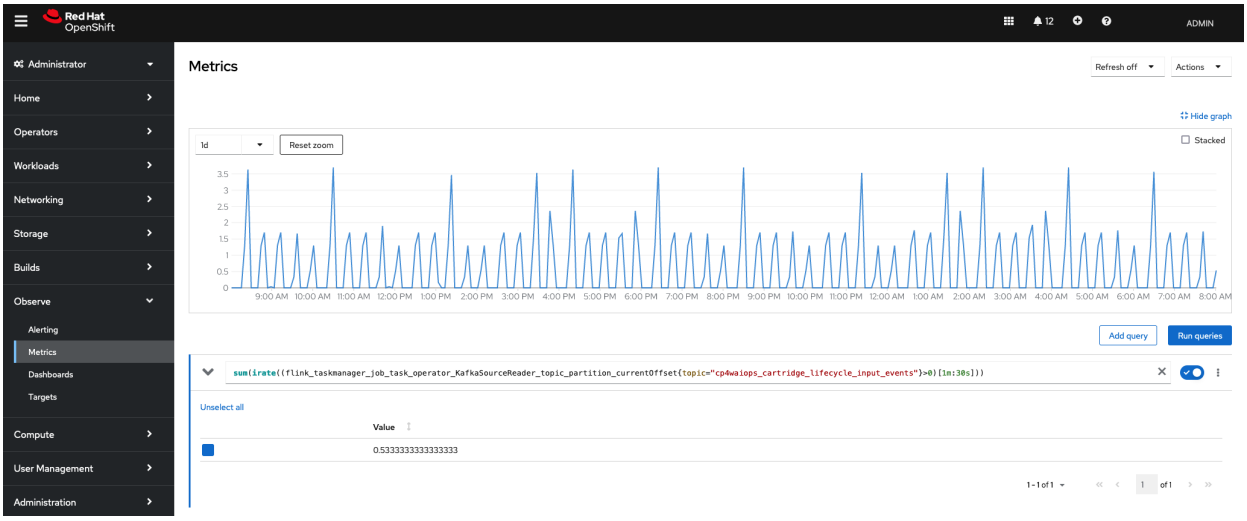

Figure. OpenShift Metrics

Topology

To view the number of resources, click **Resource Management**, and view the resource count. For example, you can see 864 resources in the following example.

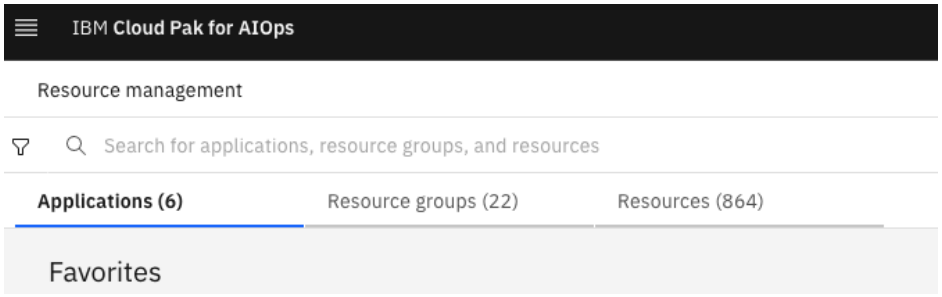

Figure. Resource management page

For more information about the Resource management, see The Resource management page.

Logs

To view the number of logs, extract the count from the Elastic backend:

1. Log in to your Red Hat® OpenShift® cluster, or SSH into a control plane node or the loadbalancer VM on your Linux® deployment. Then swtich to the namespace where IBM Cloud Pak for AIOps is installed.

   ```
   oc project <project>
   ```

   Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

2. Run the following commands to determine the names of the log data indices:

   ```
   export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o
   jsonpath='{.items[0].metadata.name}')"
   oc exec "statefulset/${ELASTIC_SET}" -- curl -XGET -k --fail "http://127.0.0.1:19200/_cat/indices?v" | grep logtrain
   ```

   Example output, where the index name is **1000-1000-20220302-logtrain**:

   ```
   green open 1000-1000-20220302-logtrain        eEvaBufQ06yG074hmeHKG  8 1 244 6 72.7kb 72.7kb
   ```

3. For each log train index, get the document count using the following command:

   ```
   export INDEX_NAME=<index_name>
   export ELASTIC_SET="$(oc get statefulset -l app.kubernetes.io/managed-by=ibm-elasticsearch -o
   jsonpath='{.items[0].metadata.name}')"
   oc exec "statefulset/${ELASTIC_SET}" -- curl -XGET -k --fail "http://127.0.0.1:19200/${INDEX_NAME}/_count"
   ```

   Where **<index_name>** is an index name that you found in the previous step.

The outputs of the preceding curl commands provide the daily count of the logs processed. To align with the Cloud Pak for AIOps deployment sizing, you can average the daily count of logs, or pick the maximum value from both of the curl commands.

Metrics

To view the number of Metric KPIs being tracked, click **AI Model Management** > **Metric anomaly detection**.

The number of KPIs is noted under the **Metrics analyzed** field. For example, 146 metrics were analyzed in the following example.

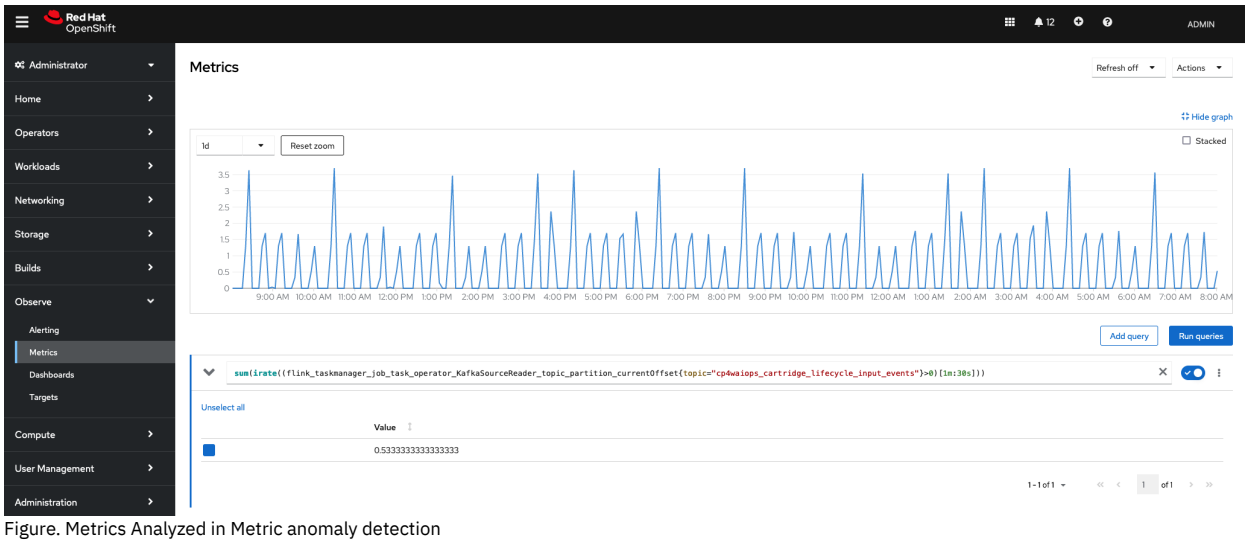

Figure. Metrics Analyzed in Metric anomaly detection

For more information about Metric anomaly detection, see the following links:

- About Metric anomaly detection.

- Setting up training for Metric anomaly detection.

Circuit breaker for Kafka robustness and stability

Enable Cloud Pak for AIOps to protect itself and remain up and running if an event storm occurs. You can implement a circuit breaker pattern to avoid Cloud Pak for AIOps failing and ensure that events, alerts, and incidents continue to be processed.

The following sections show the end-to-end flow of configuring a circuit breaker for Kafka robustness:

- Configuring prometheus.
- Creating pod monitors.
- Creating prometheus rules for generating alerts specific to Cloud Pak for AIOps Kafka storage and health.
- Push alerts generated in OpenShift to Cloud Pak for AIOps by using a webhook integration.
- Create Cloud Pak for AIOps policies to generate incidents.
- Integrate incidents with Cloud Pak for AIOps automations.

Note: There is some overlap with the initial two steps of these instructions and the procedure for Monitoring with Prometheus and Grafana.

Use cases for circuit breaker

- Monitoring the health of Kafka for restarts, failures, and so on. Sending a high priority alert that different components can take action on.
- Monitor and react to the amount of storage being used by the Kafka PVC.
- Too much data to Kafka and the databases it feeds into runs out of storage.

View the following sub-topics for details on implementing a circuit breaker pattern for Kafka:

- Creating a cluster monitoring configmap object
- Creating a user-defined workload monitoring configmap
- Configuring core OpenShift Container Platform monitoring components
- Configuring components that monitor user-defined projects
- Creating Prometheus rule to generate OpenShift alerts
- Push alerts that are generated in OpenShift into Cloud Pak for AIOps by using a webhook integration
- Creating a policy to promote critical Prometheus alerts to an incident

Note: There is some overlap with the initial two steps of these instructions and the procedure for Monitoring with Prometheus and Grafana.

Creating a cluster monitoring configmap object

You can configure the core OpenShift Container Platform monitoring components by creating the **`cluster-monitoring-config`** configmap object in the **`openshift-monitoring`** project. The Cluster Monitoring Operator (CMO) then configures the core components of the monitoring stack.

Prerequisites

- You must have access to the cluster as a user with the **`cluster-admin`** role.
- OpenShift command-line interface is required. For more information, see Getting started with the OpenShift CLI.

Procedure

- Check if the cluster-monitoring-config configmap object exists:

  ```
  oc -n openshift-monitoring get configmap cluster-monitoring-config
  ```

- If the configmap object does not exist:

  Create the following YAML manifest. In this example, the file is called cluster-monitoring-config.yaml:

  ```
  apiVersion: v1
  kind: ConfigMap
  metadata:
    name: cluster-monitoring-config
    namespace: openshift-monitoring
  data:
    config.yaml: |
  ```

  - Apply the configuration to create the configmap object:

    ```
    oc apply -f cluster-monitoring-config.yaml
    ```

Creating a user-defined workload monitoring configmap

You can configure the user workload monitoring components with the **user-workload-monitoring-config** configmap object in the **openshift-user-workload-monitoring** project. The Cluster Monitoring Operator (CMO) then configures the components that monitor user-defined projects.

Prerequisites

- You must have access to the cluster as a user with the **cluster-admin** role.
- OpenShift command-line interface is required. For more information, see Getting started with the OpenShift CLI.

Procedure

- Check if the **user-workload-monitoring-config** configmap object exists:

  ```
  oc -n openshift-user-workload-monitoring get configmap user-workload-monitoring-config
  ```

- If the **user-workload-monitoring-config** configmap object does not exist:

  Create the following YAML manifest. In this example, the file is called **user-workload-monitoring-config.yaml**:

  ```
  apiVersion: v1
  kind: ConfigMap
  metadata:
    name: user-workload-monitoring-config
    namespace: openshift-user-workload-monitoring
  data:
    config.yaml: |
  ```

  - Apply the configuration to create the configmap object:

    ```
    oc apply -f user-workload-monitoring-config.yaml
    ```

Configuring core OpenShift Container Platform monitoring components

- Edit the **cluster-monitoring-config** configmap object in the **openshift-monitoring** project.
- Add your configuration under data/config.yaml as a key-value pair <component_name>: <component_configuration>.

  For more information about configurations options, see https://docs.redhat.com/documentation/openshift_container_platform/4.17/html/monitoring/config-map-reference-for-the-cluster-monitoring-operator#cluster-monitoring-operator-configuration-reference.

- **Configmap updates**: enables userworkload and object configures a persistent volume claim (PVC) for Prometheus. This relates to the Prometheus instance that monitors core OpenShift Container Platform components only. Get the default OpenShift Container Platform storage class from the script below and then run the update command:

  ```
  if [[ -z "${PROJECT_CP4AIOPS}" ]]; then
    echo "ERROR: PROJECT_CP4AIOPS is not set"
    exit 1
  fi

  if [[ -z "${OCP_MONITOR_STORAGE_CLASS}" ]]; then
    OCP_MONITOR_STORAGE_CLASS=$(oc get sc -o jsonpath='{.items[?
  (@.metadata.annotations.storageclass\.kubernetes\.io/is-default-class=="true")].metadata.name}')
    if [[ -z "${OCP_MONITOR_STORAGE_CLASS}" ]]; then
      OCP_MONITOR_STORAGE_CLASS=$(oc get sc -o jsonpath='{range .items[*]}{.metadata.name}{"\n"}{end}' | grep 'rbd$')
      if [[ -z "${OCP_MONITOR_STORAGE_CLASS}" ]]; then
        echo "ERROR: Could not find a suitable storage class for OCP Monitoring"
        exit $LINENO
      fi
    fi
  fi
  ```

- Run the following command before running the script, or replace it with the Cloud Pak for AIOps namespace in the script.

  ```
  export PROJECT_CP4AIOPS=<aiops-namespace>
  ```

- Execute the command to apply the changes:

  ```
  cat << EOF | oc apply --validate -f -
  apiVersion: v1
  kind: ConfigMap
  metadata:
    name: cluster-monitoring-config
    namespace: openshift-monitoring
  data:
    config.yaml: |
      enableUserWorkload: true
      prometheusK8s:
        volumeClaimTemplate:
          spec:
            storageClassName: ${OCP_MONITOR_STORAGE_CLASS}
            volumeMode: Filesystem
            resources:
  ```

```
          requests:
            storage: 40Gi
```

Configuring components that monitor user-defined projects

- Edit the **cluster-monitoring-config** configmap object in the **openshift-monitoring project**:

```
cat << EOF | oc apply --validate -f -
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    prometheus:
      retention: 24h
      resources:
        requests:
          cpu: 200m
          memory: 2Gi
EOF
```

  For more information about **UserWorkloadConfiguration** options, see https://docs.redhat.com/documentation/openshift_container_platform/4.17/html/monitoring/config-map-reference-for-the-cluster-monitoring-operator#userworkloadconfiguration.

  - Defines the Prometheus component and the subsequent lines define its configuration.
  - Configures a twenty-four-hour data retention period for the Prometheus instance that monitors user-defined projects.
  - Defines a minimum resource request of 200 millicores for the Prometheus container.
  - Defines a minimum pod resource request of 2 GiB of memory for the Prometheus container.

Creating Prometheus rule to generate OpenShift alerts

Wait for user monitoring to be running and create a Prometheus rule to generate OpenShift alerts.

- Run the following command before running the script, or replace it with the Cloud Pak for AIOps namespace in the script.

```
export PROJECT_CP4AIOPS=<aiops-namespace>
```

- **Example**: alerts that inform you when the targets are down and when the enforced sample limit is approaching.

```
cat << EOF | oc apply --validate -f -

- **Example**: Red Hat OpenShift Container Platform alert when Kafka is running out of space.

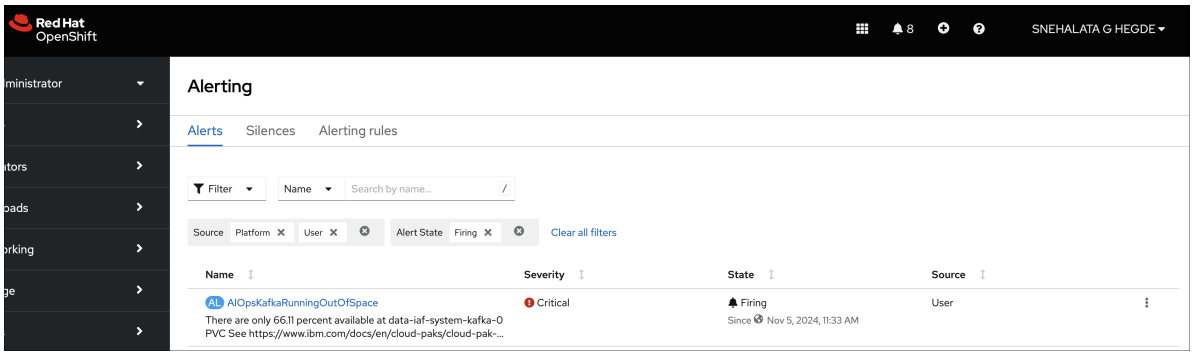

Figure. Red Hat OpenShift Container Platform alert when Kafka is running out of space

Push alerts that are generated in OpenShift into Cloud Pak for AIOps by using a webhook integration

- Follow the steps that are documented in Self-monitoring with alerts.

  Note: You can configure a webhook to only send the **`AIOpsKafka`** related alerts and severity levels.

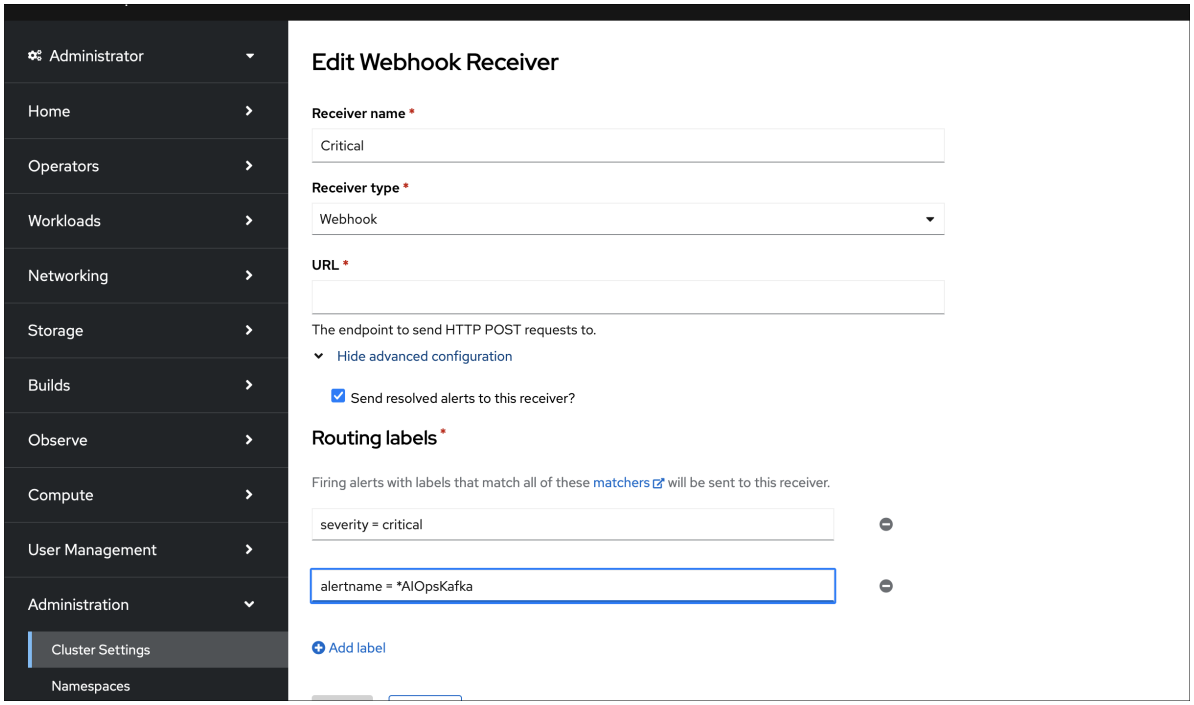

Figure. AIOpsKafka alerts and severity levels

- For the certificate manager to trust the webhook url without any certificate issues, add the Cloud Pak for AIOps CA signing cert to the OpenShift CA bundle.

  For use in insecure mode:

```
receivers:
- name: Default
  webhook_configs:
    - url: >-
        https://whconn-6d6f3a29-ddaf-4d5f-938b-6935791b5144-cp4waiops.apps.groot.cp.fyre.ibm.com/webhook-
connector/6oon1rwn4vn
      http_config:
        tls_config:
          insecure_skip_verify: true
- name: Watchdog
- name: Critical
  webhook_configs:
    - url: >-
        https://whconn-6d6f3a29-ddaf-4d5f-938b-6935791b5144-cp4waiops.apps.groot.cp.fyre.ibm.com/webhook-
connector/6oon1rwn4vn
      http_config:
        tls_config:
          insecure_skip_verify: true
```

- Alert surfacing in Cloud Pak for AIOps:

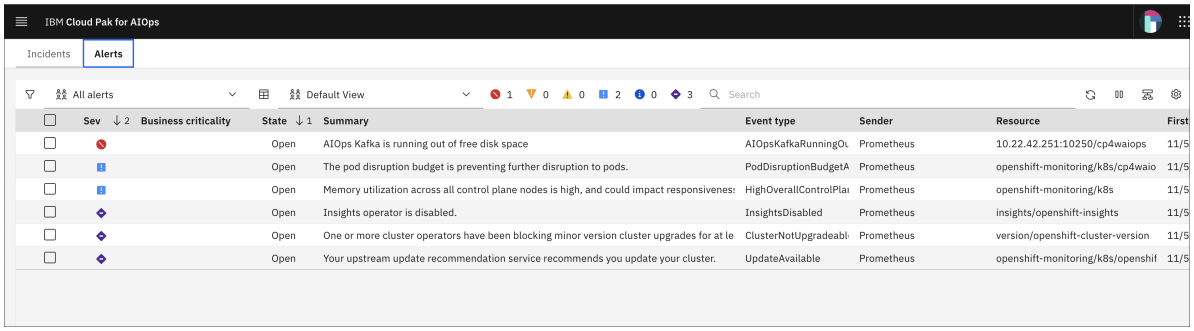

Figure. Alert surfacing in Cloud Pak for AIOps

- Alert details in Cloud Pak for AIOps:

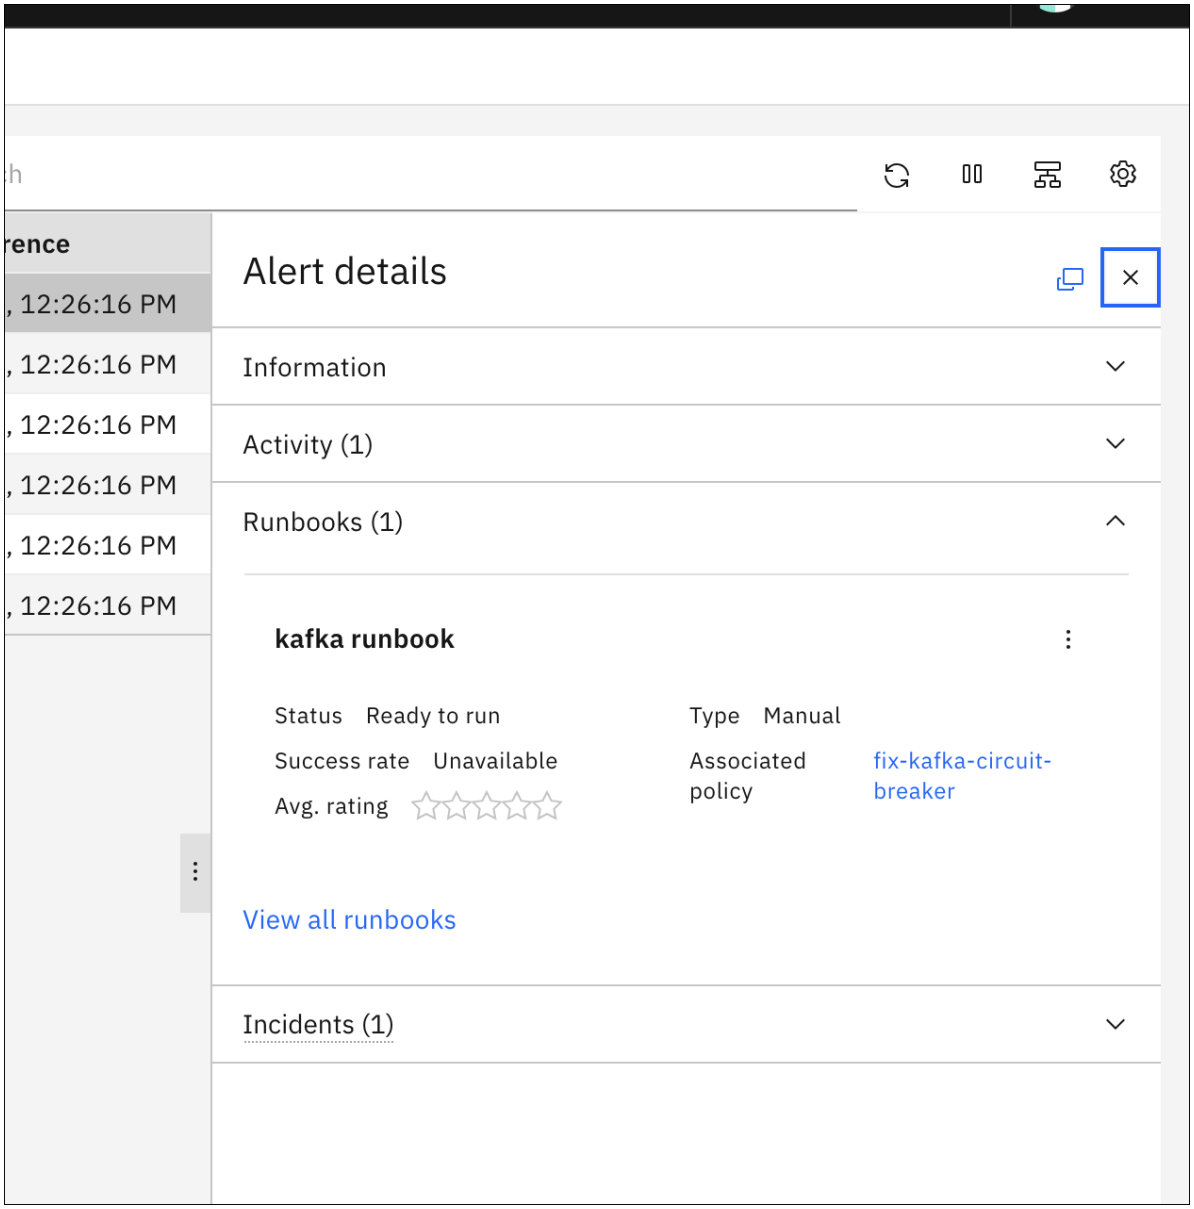

Figure. Cloud Pak for AIOps alert details

Creating a policy to promote critical Prometheus alerts to an incident

Create a policy to group the critical alerts from Prometheus that are related to Kafka and generate an incident in Cloud Pak for AIOps.

- Create a policy to Promote alerts to an incident.

  Example:

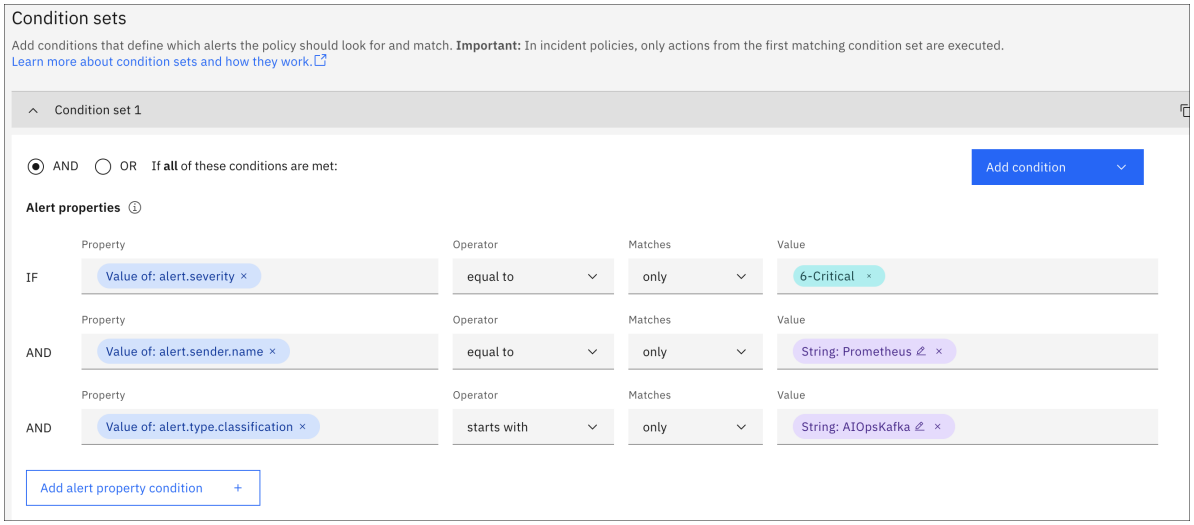

Figure. Policy to promote critical Prometheus alerts to an incident

Integrate the generated incidents with Cloud Pak for AIOps automations

- Create a policy to Assign a runbook to alerts to assign a runbook with the same set of conditions.
- An Incident is created when the alerts are generated. Details of runbooks are included in the alert details.
- Actions to stabilize examples: disable data flow for integrations, disable an existing integrations, and so on.

Certificate management (IBM Cloud Pak for AIOps on OpenShift)

With IBM Cloud Pak for AIOps, you can use IBM Cert Manager to manage your certificates or a certificate manager of your choosing. IBM Cert Manager is a service provided with IBM Cloud Pak® foundational services.

The procedure for installing a certificate for IBM Cloud Pak for AIOps depends on the certificate or endpoint that you want to secure.

- Red Hat OpenShift Container Platform certificates
- IBM Cloud Pak foundational services IBM Cert Manager certificates

Red Hat OpenShift Container Platform certificates

Red Hat OpenShift Container Platform cluster certificate

Once you have a certificate manager, you can then use the Red Hat OpenShift Container Platform cluster certificate or your own custom certificate for IBM Cloud Pak for AIOps (or a standalone installation of Infrastructure Automation) instead of the Red Hat OpenShift Container Platform. For more information, see Using a custom certificate.

Red Hat OpenShift Container Platform console certificate

This certificate is for the Red Hat OpenShift Container Platform console and is typically for use of only the cluster administrator, rather than other IBM Cloud Pak for AIOps users. It is critical that the certificate does not include the **`cp-console`** or the **`cpd-aiops`** routes in the certificate.

The default ingress certificate for Red Hat OpenShift Container Platform can have only a SAN of:

```
DNS.1 = *.apps.mycluster.example.com
```

For more information, see Red Hat OpenShift Container Platform certificate.

IBM Cloud Pak foundational services - IBM Cert Manager certificates

To add and manage certificates for IBM Cloud Pak for AIOps, you can use IBM Cert Manager, which is included with IBM Cloud Pak foundational services. With IBM Cert Manager installed, you can begin to use the available capabilities to add and manage your certificates. The IBM Cloud Pak for AIOps installation procedures include steps to optionally install IBM Cloud Pak foundational services Cert Manager.

For more information about the IBM Cloud Pak foundational services Cert Manager, see Using IBM Certificate manager (cert-manager).

Using a custom certificate

Learn how to add a custom certificate to a deployment of IBM Cloud Pak for AIOps or Infrastructure Automation on Red Hat OpenShift.

If you want to use your own custom certificate for IBM Cloud Pak® for AIOps or Infrastructure Automation instead of the Red Hat® OpenShift® Container Platform cluster certificate, then complete the following steps after you have installed IBM Cloud Pak® for AIOps or Infrastructure Automation.

1. Export an environment variable containing your project's name.

   ```
   export PROJECT=<project>
   ```

   Where **<project>** is the project (namespace) where IBM Cloud Pak for AIOps or Infrastructure Automation is deployed.

2. Ensure that you have created the following four PEM-encoded certificate files.

   - **cachain.pem**: A certificate chain containing the root and intermediate certificates.
   - **carootcert.pem**: The root certificate of your Certificate Authority (CA), with no intermediate or application certificates.
   - **aiops.key.pem**: A key file for the signed certificate in **aiops.pem**.
   - **aiops.pem**: A IBM Cloud Pak for AIOps or Infrastructure Automation certificate, which includes the two fully qualified domain names (FQDNs) for **cpd-${PROJECT}** and **cp-console-${PROJECT}** in the Subject Alternative Name (SAN) list.

   You can find the FQDNs for **cp-console-${PROJECT}** and **cpd-${PROJECT}** with the following commands.

   ```
   oc get route cp-console -n ${PROJECT} -o jsonpath="{.spec.host}"
   oc get route cpd -n ${PROJECT} -o jsonpath="{.spec.host}"
   ```

3. Add your root CA to the CA bundle, to ensure that it is trusted across the Red Hat OpenShift cluster.

   For more information, see the instructions in Replacing the CA Bundle certificate.

4. Create a secret called **custom-tls-secret** with your custom certificates.

   ```
   oc project ${PROJECT}
   oc create secret generic custom-tls-secret --from-file=ca.crt=./cachain.pem --from-file=tls.crt=./aiops.pem --from-
   file=tls.key=./aiops.key.pem
   ```

5. Create a file named **cs-onprem-tenant-config.yaml** with the following contents:

   ```
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cs-onprem-tenant-config
     labels:
       cs_onprem_tenant_config: "true"
   data:
     custom_host_certificate_secret: custom-tls-secret
   ```

6. Run the following command to create the ConfigMap:

   ```
   oc apply -f cs-onprem-tenant-config.yaml -n $PROJECT
   ```

7. Restart the **nginx** pods to pickup the new custom certificates.

   ```
   oc delete pod -l component=ibm-nginx
   ```

8. Patch **ZenService** with the new **custom-tls-secret**.

   ```
   oc patch ZenService/iaf-zen-cpdservice --type merge -p '{"spec":{"zenCustomRoute":
   {"route_reencrypt":true,"route_secret": "custom-tls-secret"}}}'
   ```

9. Patch the **cp-console** route with the new **custom-tls-secret**.

   ```
   oc patch route cp-console -p '{"spec":{"tls":{"certificate":"'"$(oc get secret custom-tls-secret -o
   jsonpath='{.data.tls\.crt}' | base64 -d | tr '\n' ':' | sed 's/:/\\n/g')"'", "key":"'"$(oc get secret custom-tls-
   secret -o jsonpath='{.data.tls\.key}'| base64 -d | tr '\n' ':' | sed 's/:/\\n/g')"'", "caCertificate":"'"$(oc get
   secret custom-tls-secret -o jsonpath='{.data.ca\.crt}' | base64 -d | tr '\n' ':' | sed 's/:/\\n/g')"'"}}}'
   ```

10. Run the following commands:

    ```
    oc -n ${PROJECT} delete pod -l app=platform-auth-service
    oc -n ${PROJECT} delete pod -l app=platform-identity-provider
    oc -n ${PROJECT} delete pod -l name=ibm-zen-operator
    oc -n ${PROJECT} delete pod -l component=usermgmt
    oc -n ${PROJECT} delete pod -l name=operand-deployment-lifecycle-manager
    ```

11. Wait for around 15 minutes for these updates to be reconciled, and for the new configuration to be in place.

    You can check the progress of the reconciliation with the following commands:

    ```
    oc get zenservice iaf-zen-cpdservice -o jsonpath='{.status.Progress}'
    oc get zenservice iaf-zen-cpdservice -o jsonpath='{.status.ProgressMessage}'
    ```

    When **Progress** is shown as *100%*, then reconciliation is complete and you can log in to the console.

Rebalancing workloads on a multi-zone architecture (IBM Cloud Pak for AIOps on OpenShift)

BETA The use of the multi-zone high availability (HA) deployment architecture for IBM Cloud Pak for AIOps is available only for technology preview, and is not for production usage.

Use these steps to manually redistribute IBM Cloud Pak® for AIOps workloads across a multi-zone Red Hat® OpenShift® Container Platform cluster.

Overview

For more information about deploying IBM Cloud Pak for AIOps on a multi-zone cluster, see Installing IBM Cloud Pak for AIOps on a multi-zone architecture (multi-zone HA).

The distribution of IBM Cloud Pak for AIOps workloads across the zones in your multi-zone cluster is important to help ensure high availability. You might need to rebalance your workloads manually to achieve an optimal distribution.

If a zone outage occurs in a multi-zone cluster, Red Hat OpenShift automatically reschedules IBM Cloud Pak for AIOps workloads on the affected zone to alternative available zones. This helps IBM Cloud Pak for AIOps to continue functioning during a zone outage, but it means that workloads are not optimally distributed when the affected zone is restored. Rebalancing is then needed to help ensure that all available zones have sufficient replicas to maintain high availability if another zone outage occurs. Red Hat OpenShift does not automatically rebalance workloads because it can be disruptive and cause further problems. Rebalancing must be done manually when convenient, for example during a scheduled maintenance window.

Procedure

Use the following steps to correct the distribution of workloads, for example after the restoration of a failed zone.

1. Check whether all the recovered nodes are healthy.

   Run the following command to validate the readiness of all nodes:

   ```
   oc get nodes
   ```

   Example output:

   ```
   $ oc get nodes
   NAME                 STATUS   ROLES                  AGE    VERSION
   master0.acme.com     Ready    control-plane,master   4d3h   v1.27.13+048520e
   master1.acme.com     Ready    control-plane,master   4d3h   v1.27.13+048520e
   master2.acme.com     Ready    control-plane,master   4d3h   v1.27.13+048520e
   worker0.acme.com     Ready    infra,worker           4d3h   v1.27.13+048520e
   worker1.acme.com     Ready    infra,worker           4d3h   v1.27.13+048520e
   worker10.acme.com    Ready    worker                 4d3h   v1.27.13+048520e
   worker11.acme.com    Ready    worker                 4d3h   v1.27.13+048520e
   worker12.acme.com    Ready    worker                 4d3h   v1.27.13+048520e
   worker13.acme.com    Ready    worker                 4d3h   v1.27.13+048520e
   worker14.acme.com    Ready    worker                 4d3h   v1.27.13+048520e
   worker2.acme.com     Ready    infra,worker           4d3h   v1.27.13+048520e
   worker3.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   worker4.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   worker5.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   worker6.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   worker7.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   worker8.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   worker9.acme.com     Ready    worker                 4d3h   v1.27.13+048520e
   ```

   Do not proceed until all nodes have a **STATUS** of **Ready**.

2. Assess whether workloads are distributed well.

   Download the status checker plug-in from github.com/IBM. Run the following command to assess the distribution of IBM Cloud Pak for AIOps workloads across your cluster zones:

   ```
   oc waiops multizone status
   ```

   No further action is needed if the script reports **INFO: All pods are distributed appropriately for multizone.**

   Example output where pods are not optimally distributed across zones:

   ```
   $ oc waiops multizone status

   Regions : CentralNC
   Zones   : ChapelHill Durham Raleigh

   NAME                 ZONE          REGION
   worker11.acme.com    ChapelHill    CentralNC
   worker14.acme.com    ChapelHill    CentralNC
   worker2.acme.com     ChapelHill    CentralNC
   worker5.acme.com     ChapelHill    CentralNC

aiops       platform-identity-provider-649c6dd6cd-jfhmc           Durham       worker4.acme.com    Deployment
aiops       platform-identity-provider-649c6dd6cd-hc9v5           Raleigh      worker12.acme.com   Deployment
```

In the preceding example output, pods that are not optimally distributed are listed after **`WARNING: Not all pods are distributed optimally`**. The distribution is suboptimal because pod replicas are on the same zone, instead of being across distinct zones.

3. Manually redistribute the identified pods on the multi-zone cluster to achieve an optimal distribution for high availability.

   For each microservice identified in the previous step, delete pods that have the same zone as another pod within that microservice - an example is given at the end of this step. The order of deletion is significant. If the pods identified by the status checker plug-in contain any of the following, then delete them in the following order before you delete any other pods:

   - **`iaf-system-zookeeper`**
   - **`iaf-system-kafka`**
   - **`aiops-topology-cassandra`**
   - **`aiops-ibm-elasticsearch-es-server-zone0`**
   - **`aiops-ibm-elasticsearch-es-server-zone1`**
   - **`aiops-ibm-elasticsearch-es-server-zone2`**
   - **`aiops-ir-analytics-spark-worker`**
   - **`aiops-lad-flink-taskmanager`**
   - **`aiops-lad-flink`**
   - **`aiops-ir-lifecycle-flink-taskmanager`**
   - **`aiops-ir-lifecycle-flink`**
   - **`<instance>-edb-postgres`**, where **`<instance>`** is the name of your IBM Cloud Pak for AIOps instance, usually **`ibm-cp-aiops`**.
   - **`aiops-ir-lifecycle-datarouting`**
   - **`aimanager-aio-similar-incidents-service`**
   - **`aimanager-aio-log-anomaly-golden-signals`**
   - **`aiops-topology-topology`**
   - **`aimanager-aio-change-risk`**
   - **`aiops-ir-core-ncoprimary`**
   - **`aiops-ir-core-ncobackup`**
   - **`<instance>-redis-server`**, where **`<instance>`** is the name of your IBM Cloud Pak for AIOps instance, usually **`ibm-cp-aiops`**.
   - **`aiops-topology-layout`**

   Note: To achieve an optimal distribution, delete pods individually. You can delete multiple pods together if you need to reduce disruption time.

   Run the following command to delete a pod:

   ```
   oc delete pod -n <project> <pod_to_delete>
   ```

   Where

   - **`<project>`** is the project that your IBM Cloud Pak for AIOps installation is deployed in.
   - **`<pod_to_delete>`** is a pod with multiple replicas in the same zone.

   For example, the **`platform-identity-provider`** microservice in the example output for step 2 has two pods in Durham and one pod in Raleigh. Delete a pod in Durham so that a new pod can be scheduled on a node in the Chapel Hill zone, achieving distribution across all zones, as in the following example:

   Example command:

   ```
   oc delete pod -n aiops platform-identity-provider-649c6dd6cd-45v7c
   ```

4. Validate whether the distribution is now optimal.

   Re-run the status checker plug-in to check that all pods are now optimally distributed across the cluster zones.

   ```
   oc waiops multizone status
   ```

   Example output where pods are optimally distributed across zones:

   ```
   $ oc waiops multizone status

   Regions : CentralNC
   Zones   : ChapelHill Durham Raleigh

   NAME                ZONE         REGION
   ```

```
worker11.acme.com   ChapelHill   CentralNC
worker14.acme.com   ChapelHill   CentralNC
worker2.acme.com    ChapelHill   CentralNC
worker5.acme.com    ChapelHill   CentralNC
worker8.acme.com    ChapelHill   CentralNC
worker1.acme.com    Durham       CentralNC
worker10.acme.com   Durham       CentralNC
worker13.acme.com   Durham       CentralNC
worker4.acme.com    Durham       CentralNC
worker7.acme.com    Durham       CentralNC
worker0.acme.com    Raleigh      CentralNC
worker12.acme.com   Raleigh      CentralNC
worker3.acme.com    Raleigh      CentralNC
worker6.acme.com    Raleigh      CentralNC
worker9.acme.com    Raleigh      CentralNC

INFO: Checking the namespace aiops.................................done.

INFO: All pods are distributed appropriately for multizone.
```

If the status checker plug-in still reports a nonoptimal distribution, then repeat step 3. If the service remains incorrectly distributed, then you can run the following command to cordon nodes within a zone so that deleted pods cannot be rescheduled on them:

```
oc adm cordon $(oc get no -l topology.kubernetes.io/zone=<zone_name> -o jsonpath='{.items[*].metadata.name}')
```

Where **<zone_name>** is the name of the zone that you do not want pods to be scheduled in.

Example command to cordon nodes in the Durham zone to help ensure that a pod is not scheduled in the Durham zone:

```
oc adm cordon $(oc get no -l topology.kubernetes.io/zone=Durham -o jsonpath='{.items[*].metadata.name}')
```

When the service has an optimal distribution, uncordon the nodes:

```
oc adm uncordon $(oc get no -l topology.kubernetes.io/zone=<zone_name>> -o jsonpath='{.items[*].metadata.name}')
```

Where **<zone_name>** is the name of the zone that you do not want pods to be scheduled in.

Example command:

```
oc adm uncordon $(oc get no -l topology.kubernetes.io/zone=Durham -o jsonpath='{.items[*].metadata.name}')
```

Resizing storage (IBM Cloud Pak for AIOps on OpenShift)

Learn about increasing the persistent volume claim (PVC) sizes for IBM Cloud Pak for AIOps.

The original PVC sizes in Persistent storage sizing provide adequate space for a user to begin working with IBM Cloud Pak for AIOps. Based on your actual usage and needs, the PVCs might need to be adjusted up to handle the workload when IBM Cloud Pak for AIOps is installed and running. In particular, CouchDB, Elasticsearch, and Kafka might need significantly more disk space. Expand the following sections to review details about custom sizings for these PVCs.

Cassandra

Cassandra is used to primarily store Topology Management resources, as well as incoming metric and alert data. By default, 50 GB is allocated for each of the 3 Cassandra instances (PVCs). This default configuration is targeted for environments with less than 500,000 topology resources to provide ample storage for topology resources, metric data (120K metrics per 5 minute KPI window), and Cassandra's internal data management activities. For environments with larger topology resource requirements, an additional 70 GB is recommended for each additional 1M topology resources, and an additional 15 GB for each additional 100K metrics per 5 minute KPI window for Metric storage.

In comparison to a default production environment, a larger environment requires additional storage. For example:

Example 1: An environment with 1.5M topology resources, and 120,000 metrics per 5 minute KPI window would require an additional 70 GB of storage for topology resources, no additional storage for metric processing, for a total of 120 GB required per Cassandra storage PVC.

Example 2: An environment with 3M topology resources, and 1.2M metrics per 5 minute KPI window would require an additional 210 GB for Topology storage and an additional 135 GB for Metric storage should be allocated to raise the total Cassandra allocation (per PVC) from the default of 50 GB to 395 GB of storage per Cassandra storage PVC.

Increasing the size of the Cassandra PVCs

You can increase the configured Cassandra storage size if you need to support more than the default configuration supports. You can also incrementally add disk storage as resource counts or metric rates increase over time. To add disk storage, use the Red Hat OpenShift (oc) CLI to scale your PVC storage:

1. Export environment variables and switch to your project.

```
export PROJECT=<project>
export INSTALLATION_NAME="$(oc get installation -n ${PROJECT} -o jsonpath="{.items[0].metadata.name}")"
export SIZE=<size>Gi

oc project ${PROJECT}
```

Where

- `<project>` is the project that your IBM Cloud Pak for AIOps installation is deployed in.
- `<size>` is the storage size that you require for the Cassandra PVCs in Gi. For example, if you require 110Gi use `export SIZE=110Gi`.

2. Run the following command to increase Cassandra's PVC claims.

```
oc patch installation ${INSTALLATION_NAME} --type merge -p '{"spec":{"storage":{"data-aiops-topology-cassandra":
{"size":"'${SIZE}'"}}}}'
```

CouchDB

CouchDB is used to store the results of manually run and fully automated runbook activities. CouchDB storage is uncapped to allow you access to historical activities. Each CouchDB PVC is set with a default value of 20 GB of storage.

As an example, in a small environment with an average of 60 runbook executions per hour (1 per minute, 1440 per day), you budget about 20 MB of storage for CouchDB per day. In a Large (high availability) deployment, with the same rate of runbook executions, you budget 60 MB of storage space for CouchDB per day. By using the default CouchDB storage sizes with this example scenario, the default storage for IBM Cloud Pak for AIOps supports about 1000 days of retention.

A sample runbook is provided to reduce the historical storage footprint when needed. For more information about sample runbooks, see Load and reset example runbooks.

EDB Postgres

Increasing the size of the Postgres PVCs

1. Export environment variables and switch to your project.

```
export PROJECT=<project>
export INSTALLATION_NAME="$(oc get installation -n ${PROJECT} -o jsonpath="{.items[0].metadata.name}")"
export SIZE=<size>Gi

oc project ${PROJECT}
```

Where

- `<project>` is the project that your IBM Cloud Pak for AIOps installation is deployed in.
- `<size>` is the storage size that you require for the Postgres PVCs in Gi. For example, if you require 110Gi use `export SIZE=110Gi`.

2. Run the following command to increase EDB Postgres's PVC claim.

```
oc patch installation ${INSTALLATION_NAME} --type merge -p '{"spec":{"storage":{"ibm-cp-aiops-edb-postgres":
{"size":"'${SIZE}'"}}}}'
```

Important: You must run the preceding command as it is, even if the name of your Postgres PVC does not start with `ibm-cp-aiops`.

Elasticsearch

Elasticsearch is used to store various data sets in IBM Cloud Pak for AIOps, the largest of which is log data for training and analysis. If there are large volumes of log data, then you might need to increase the provision for Elasticsearch. Use the instructions for Storage class requirements under the IBM Cloud Pak for AIOps only section of hardware requirements. The exact amount of Elasticsearch data, and therefore the amount of storage that is needed, varies greatly from case to case.

For estimation purposes, plan for around 10Gi of disk space usage per replica per day, running at 1000 log messages per second.

One replica of the data is stored in Elasticsearch on a starter deployment of IBM Cloud Pak for AIOps, and three copies of the data are stored in Elasticsearch for a production IBM Cloud Pak for AIOps deployment.

The default retention period for Elasticsearch data is 14 days, so plan for 15 days of storage.

The total estimated space must be available across all of the Elasticsearch instances in the cluster combined. A starter deployment of IBM Cloud Pak for AIOps has one Elasticsearch node, and a production IBM Cloud Pak for AIOps deployment has five Elasticsearch nodes.

Plan for a minimum of a 20% buffer to allow for variations in log data size.

Example 1: Running at 4000 logs per second on a starter deployment for 14+ days.

- This would be roughly 40Gi x 15 days x 1 replica = 600Gi of Elasticsearch PVC usage.
- Multiply this by a buffer of 1.2.
- This results in a recommendation of 720Gi in total for the one Elasticsearch instance deployed by default in a starter deployment.
- Set the storage size for the Elasticsearch PVC to 720Gi.

Example 2: Running at 8000 logs per second on a production deployment for 14+ days.

- This would be roughly 80Gi x 15 days x 3 replicas = 3600Gi of Elasticsearch PVC usage.
- Multiply this by a buffer of 1.2.
- This results in a recommendation of 4,320Gi total across all five Elasticsearch instances, or roughly 864Gi per instance.
- Set the storage size for the Elasticsearch PVC to 864Gi.

Increasing the size of the Elasticsearch PVCs

1. Export environment variables and switch to your project.

```
export PROJECT=<project>
export INSTALLATION_NAME="$(oc get installation -n ${PROJECT} -o jsonpath="{.items[0].metadata.name}")"
```

```
export SIZE=<size>Gi

oc project ${PROJECT}
```

Where

- **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.
- **<size>** is the storage size that you require for the Elasticsearch PVCs in Gi. For example, if you require 110Gi use **export SIZE=110Gi**.

2. Run the following command to increase Elasticsearch's PVC claims, where **<size>** is the storage size that you require for Elasticsearch's PVCs.

```
oc patch installation ${INSTALLATION_NAME} --type merge -p '{"spec":{"storage":{"data-aiops-ibm-elasticsearch-es-server-all":{"size":"'${SIZE}'"}}}}'
```

Important: If you have a multizone environment, the name of your PVC might end with the zone name instead of **all**, but it is important that the preceding codeblock is run as it is, with **data-aiops-ibm-elasticsearch-es-server-all**.

Kafka

Kafka's storage requirements are primarily driven by Kafka log integrations, and also by other integrations such as Topology observers and Metric integrations, including custom Metric integrations.

The amount of storage that Kafka needs varies depending on your usage, and you might need to increase the storage provision for Kafka. Data collection from a metric data source commonly starts with historical data collection. For this reason, it is good practice to increase the PVC size for Kafka.

Increasing the size of the Kafka PVCs

You can increase Kafka's PVC size with the following commands. The Kafka pods will then restart with the resized PVCs.

1. Export environment variables and switch to your project.

```
export PROJECT=<project>
export INSTALLATION_NAME="$(oc get installation -n ${PROJECT} -o jsonpath="{.items[0].metadata.name}")"
export SIZE=<size>Gi

oc project ${PROJECT}
```

Where

- **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.
- **<size>** is the storage size that you require for the Kafka PVCs in Gi. For example, if you require 110Gi use **export SIZE=110Gi**.

2. Run the following command to increase Kafka's PVC claim, where **<size>** is the storage size that you require for Kafka's PVCs.

```
oc patch installation ${INSTALLATION_NAME} --type merge -p '{"spec":{"storage":{"data-iaf-system-kafka":{"size":"'${SIZE}'"}}}}'
```

Notes:

- For Metric Anomaly Detection, it is recommended to increase the persistent storage for Kafka by 2Gi for every 10,000 KPIs being processed.
- For Log Anomaly Detection, it is recommended to increase the Kafka PVC space based on the size of the logs, plus roughly an additional 20% buffer due to overheads, such as the key strings that are added to the messages.
- For example, if you plan on uploading 40Gi of log data then add around 48Gi (40Gi plus a 20% buffer) to the existing 30Gi for a total of 78Gi for the Kafka PVC.

MinIO

Increasing the size of the MinIO PVCs

1. Switch to your IBM Cloud Pak for AIOps project.

```
oc project <project>
```

Where **<project>** is the project that your IBM Cloud Pak for AIOps installation is deployed in.

2. Run the following command to increase MinIO's PVC claims, where **<size>** is the storage size that you require for the MinIO PVCs.

```
for p in $(oc get pvc -l app.kubernetes.io/name=ibm-minio -o jsonpath='{.items[*].metadata.name}'); do oc patch pvc $p --type merge -p '{"spec":{"resources":{"requests":{"storage":"<size>Gi"}}}}' ; done
```

For example, to change the MinIO PVC size to 80Gi:

```
for p in $(oc get pvc -l app.kubernetes.io/name=ibm-minio -o jsonpath='{.items[*].metadata.name}'); do oc patch pvc $p --type merge -p '{"spec":{"resources":{"requests":{"storage":"80Gi"}}}}' ; done
```

3. Delete the **aimanager-ibm-minio** StatefulSet and leave its pods.

```
oc delete sts --cascade=orphan aimanager-ibm-minio
```

4. Run the following command to update the **aimanager** custom resource with the new MinIO storage size, where **<size>** is the storage size that you set for the MinIO PVCs.

```
oc patch aimanager aimanager --type='json' -p="[{'op': 'replace', 'path': '/spec/minio/storage/storageSize', 'value': '<size>Gi'}]"
```

For example, if MinIO PVC size is updated to 80Gi:

```
oc patch aimanager aimanager --type='json' -p="[{'op': 'replace', 'path': '/spec/minio/storage/storageSize',
'value': '80Gi'}]"
```

5. Verify that the **aimanager-ibm-minio** statefulset has the correct storage size.

```
oc get statefulset  aimanager-ibm-minio -o
jsonpath='{.spec.volumeClaimTemplates[0].spec.resources.requests.storage}'
```

Restarting the environment (IBM Cloud Pak for AIOps on OpenShift)

Learn how to shutdown and restart the Red Hat OpenShift cluster where IBM Cloud Pak for AIOps is deployed.

Overview

Use this procedure before a known maintenance window or outage to shut down the Red Hat OpenShift cluster where IBM Cloud Pak for AIOps is installed, and to restart the cluster and workloads afterward.

Warning: If you need to shut down the cluster where IBM Cloud Pak for AIOps is installed, then you must use the following procedure. Failure to do so can result in data loss or corruption.

Procedure

1. Validate the installation
2. Check the certificates
3. Prepare to scale down
4. Scale down the workloads and drain the nodes
5. Shut down the cluster
6. Restart the cluster
7. Scale up the workloads
8. Validate the installation

1. Validate the installation

1. Set environment variables.

   Make a note of these environment variables or save them to a file, as you will need to export them again after you restart your cluster.

   ```
   export AIOPS_NAMESPACE=<project>
   export AIOPS_INSTANCE=$(oc get installation -o jsonpath='{.items[0].metadata.name}' -n ${AIOPS_NAMESPACE})
   ```

   Where **<project>** is the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in.

2. Run the describe command:

   ```
   oc describe installations.orchestrator.aiops.ibm.com -n "${AIOPS_NAMESPACE}"
   ```

   Review the **ComponentStatus** fields to confirm that all components are marked as **Ready** and the phase is **Running**.

   Example output:

   ```
   Name:         ibm-cp-aiops
   Namespace:    aiops
   API Version:  orchestrator.aiops.ibm.com/v1alpha1
   Kind:         Installation
   Spec:
   ...
   Status:
   Componentstatus:
      Aimanager:                        Ready
      Aiopsanalyticsorchestrator:       Ready
      Aiopsedge:                        Ready
      Aiopsui:                          Ready
      Asm:                              Ready
      Baseui:                           Ready
      Cluster:                          Ready
      Commonservice:                    Ready
      Elasticsearchcluster:             Ready
      Flinkdeployment:                  Ready
      Issueresolutioncore:              Ready
      Kafka:                            Ready
      Lifecycleservice:                 Ready
      Lifecycletrigger:                 Ready
      Rediscp:                          Ready
      Tunnel:                           Ready
      Zenservice:                       Ready
   Phase:                    Running
   ```

2. Check the certificates

Ensure that none of the certificates have problems or are expired.

Run the following command:

```
while read l; do echo "$l" | grep '^NAME' || (n=$(echo $l | sed 's/ .*//'); s=$(echo $l | sed 's/^[^ ]* *\([^ ]*\).*/\1/'); x=$(oc get secret -n $n $s -o jsonpath='{.data.tls\.crt}' | base64 -d | openssl x509 -noout -enddate 2>/dev/null | sed 's!notAfter=!!'); echo "$l" | sed 's![^ ][^ ]*$!'"$x"'!'); done< <(oc get secret -A --field-selector=type==kubernetes.io/tls -o custom-columns=NAMESPACE:.metadata.namespace,NAME:.metadata.name,EXPIRY:.metadata.name)
```

Example output excerpt:

```
ibm-licensing   ibm-license-service-cert                                  Jan  8  13:32:07  2025  GMT
ibm-licensing   ibm-license-service-cert-internal                         Jan  7  13:31:12  2026  GMT
ibm-licensing   ibm-licensing-service-prometheus-cert                     Jan  7  13:31:25  2026  GMT
cp4aiops        aimanager-aio-log-anomaly-feedback-learning-cert          Jan  7  14:01:43  2026  GMT
cp4aiops        aimanager-aio-log-anomaly-golden-signals-cert             Jan  7  14:01:43  2026  GMT
cp4aiops        aimanager-aio-oob-recommended-actions-cert                Jan  7  14:01:43  2026  GMT
<...>
```

Renew or re-create any certificates that have problems, are expired, or will expire before the cluster is restarted. For more information about certificate management, see Renew or re-create certificates in Openshift 4.x.

3. Prepare to scale down

1. Cordon the worker nodes.

   Run the following command for each of the worker nodes:

   ```
   oc adm cordon <node>
   ```

   Where **<node>** is the name of the node to cordon.

2. Make a note of the number of replicas.

   1. Make a note of the number of replicas for each StatefulSet.

      ```
      oc get statefulsets -n ${AIOPS_NAMESPACE}
      ```

      Example output:

      ```
      NAME                                        READY   AGE
      aimanager-ibm-minio                         1/1     18m
      aiops-ir-analytics-spark-worker             2/2     33m
      aiops-ir-core-ncobackup                     1/1     37m
      aiops-ir-core-ncoprimary                    1/1     39m
      aiops-topology-cassandra                    1/1     43m
      c-example-couchdbcluster-m                  1/1     40m
      aiops-ibm-elasticsearch-es-server-all       1/1     49m
      ibm-cp-aiops-redis-server                   3/3     45m
      zen-minio                                   3/3     40m
      ```

      Note:

      - If you do not have a IBM® Netcool® Operations Insight® probe integration, then `aiops-ir-core-ncobackup` and `aiops-ir-core-ncoprimary` has zero replicas.
      - If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb` StatefulSet.

   2. Make a note of the number of replicas for each StrimziPodSet.

      ```
      oc get strimzipodset -n ${AIOPS_NAMESPACE}
      ```

      Example output:

      ```
      NAME                          PODS   READY PODS   CURRENT PODS   AGE
      iaf-system-kafka              3      3            3              13d
      iaf-system-zookeeper          3      3            3              13d
      ```

   3. Make a note of the number of replicas for each Flink deployment by using the following command:

      ```
      oc get deployment | grep flink | grep -v "operator"
      ```

      Example output:

      ```
      NAME                                    PODS   READY PODS   CURRENT PODS   AGE
      aiops-ir-lifecycle-flink                1/1     1            1             137m
      aiops-ir-lifecycle-flink-taskmanager    1/1     1            1             137m
      aiops-lad-flink                         1/1     1            1             139m
      aiops-lad-flink-taskmanager             2/2     2            2             139m
      ```

      Notes:

      - If you have a base deployment, then `aiops-lad-flink` and `aiops-lad-flink-taskmanager` do not show in the preceding output.
      - If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb` StatefulSet.

4. Scale down the workloads and drain the nodes

1. Scale down the operator deployments in the IBM Cloud Pak for AIOps namespace.

   ```
   oc scale deployment -l olm.owner.kind=ClusterServiceVersion -n ${AIOPS_NAMESPACE} --replicas=0
   ```

   Run the following command to check that the number of replicas for each of the operator deployments is now 0.

   ```
   oc get deployment -n ${AIOPS_NAMESPACE} -l olm.owner.kind=ClusterServiceVersion
   ```

   Example output:

   ```
   NAME                                                READY   UP-TO-DATE   AVAILABLE   AGE
   aimanager-operator-controller-manager               0/0     0            0           47m
   aiopsedge-operator-controller-manager               0/0     0            0           47m
   asm-operator                                        0/0     0            0           47m
   flink-kubernetes-operator                           0/0     0            0           54m
   ibm-aiops-orchestrator-controller-manager           0/0     0            0           58m
   ibm-common-service-operator                         0/0     0            0           56m
   ibm-commonui-operator                               0/0     0            0           53m
   ibm-elasticsearch-operator-ibm-es-controller-manager 0/0     0            0           54m
   ibm-events-operator-v5.0.1                          0/0     0            0           54m
   ibm-iam-operator                                    0/0     0            0           54m
   ibm-ir-ai-operator-controller-manager               0/0     0            0           47m
   ibm-redis-cp-operator                               0/0     0            0           49m
   ibm-secure-tunnel-operator                          0/0     0            0           48m
   ibm-watson-aiops-ui-operator-controller-manager     0/0     0            0           48m
   ibm-zen-operator                                    0/0     0            0           54m
   ir-core-operator-controller-manager                 0/0     0            0           47m
   ir-lifecycle-operator-controller-manager            0/0     0            0           47m
   operand-deployment-lifecycle-manager                0/0     0            0           55m
   postgresql-operator-controller-manager-1-18-12      0/0     0            0           54m
   ```

   Note: If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb-operator` deployment.

2. Scale down the StatefulSets that you noted in step 3.2.

   You can use the Cloud Pak for AIOps console, or create a shell script to do this.

   If you have a base deployment, then remove the following lines from the example shell script:

   ```
   oc scale deployment aiops-lad-flink --replicas=0 -n ${AIOPS_NAMESPACE}
   oc scale deployment aiops-lad-flink-taskmanager --replicas=0 -n ${AIOPS_NAMESPACE}
   ```

   Note:

   - If you have a base deployment, then `aiops-lad-flink` and `aiops-lad-flink-taskmanager` do not show in the preceding output.
   - If you upgraded from an earlier version of IBM Cloud Pak for AIOps, you also have an `icp-mongodb` StatefulSet.

   If you upgraded from an earlier version of IBM Cloud Pak for AIOps, then add the following line to the example shell script:

   ```
   oc scale statefulsets icp-mongodb --replicas=0 -n ${AIOPS_NAMESPACE}
   ```

   Example shell script:

   ```
   #!/bin/bash

   oc scale statefulsets aimanager-ibm-minio --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets ${AIOPS_INSTANCE}-redis-server --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets aiops-ir-analytics-spark-worker --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets aiops-ir-core-ncobackup --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets aiops-ir-core-ncoprimary --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale deployment aiops-ir-lifecycle-flink --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale deployment aiops-ir-lifecycle-flink-taskmanager --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets aiops-topology-cassandra --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets c-example-couchdbcluster-m --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale deployment aiops-lad-flink --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale deployment aiops-lad-flink-taskmanager --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets -l app.kubernetes.io/managed-by=ibm-elasticsearch --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   oc scale statefulsets zen-minio --replicas=0 -n ${AIOPS_NAMESPACE}
   sleep 2
   ```

   Run the following command to check that the number of replicas for each of the StatefulSets is now 0.

   ```
   oc get statefulsets -n ${AIOPS_NAMESPACE}
   ```

   Example output:

```
NAME                                          READY   AGE
aimanager-ibm-minio                           0/0     112m
aiops-ir-analytics-spark-worker               0/0     128m
aiops-ir-core-ncobackup                       0/0     131m
aiops-ir-core-ncoprimary                      0/0     133m
aiops-topology-cassandra                      0/0     138m
c-example-couchdbcluster-m                    0/0     134m
aiops-ibm-elasticsearch-es-server-all         0/0     143m
ibm-cp-aiops-redis-server                     0/0     140m
zen-minio                                     0/0     134m
```

3. Run the following command to check that the number of replicas for each of the Flink Deployments is now 0.

```
oc get deployments -n ${AIOPS_NAMESPACE} | grep flink | grep -v "operator"
```

Example output:

```
NAME                                  READY   UP-TO-DATE   AVAILABLE   AGE
aiops-ir-lifecycle-flink              0/0     0            0           137m
aiops-ir-lifecycle-flink-taskmanager  0/0     0            0           137m
aiops-lad-flink                       0/0     0            0           139m
aiops-lad-flink-taskmanager           0/0     0            0           139m
```

4. Shutdown the **Kafka** and **ZooKeeper** pods.

```
oc delete pod -l ibmevents.ibm.com/name=iaf-system-kafka -n ${AIOPS_NAMESPACE}
oc delete pod -l ibmevents.ibm.com/name=iaf-system-zookeeper -n ${AIOPS_NAMESPACE}
```

Run the following command to check that the Kafka and ZooKeeper pods have successfully shutdown. If the shutdown is complete, no pods are returned.

```
oc get pod -l ibmevents.ibm.com/controller=strimzipodset -n ${AIOPS_NAMESPACE}
```

5. Scale down the PostgreSQL pods.

When shutting down a PostgreSQL cluster, it is best to remove the primary replica last. The following script removes each database replica in the cluster with the primary removed last.

Before running the script, replace **<project>** with the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in.

```
#!/bin/bash

AIOPS_NAMESPACE=<project>

# Get array of Postgres clusters
CLUSTERS=($(oc get clusters.postgresql.k8s.enterprisedb.io -n "${AIOPS_NAMESPACE}" -o go-template='{{range .items}}
{{.metadata.name}}{{" "}}{{end}}'))

# For each Postgres cluster, shutdown primary last
for cluster_name in "${CLUSTERS[@]}"; do
    primary=$(oc get clusters.postgresql.k8s.enterprisedb.io -n "${AIOPS_NAMESPACE}" "${cluster_name}" -o go-
template='{{.status.currentPrimary}}')
    instances=($(oc get clusters.postgresql.k8s.enterprisedb.io -n "${AIOPS_NAMESPACE}" "${cluster_name}" -o go-
template='{{range .status.instanceNames}}{{print . " "}}{{end}}'))
    for instance_name in "${instances[@]}"; do
        # Shutdown non-primary replicas
        if [ "${instance_name}" != "${primary}" ]; then
            oc delete pod -n "${AIOPS_NAMESPACE}" "${instance_name}" --ignore-not-found
        fi
    done

    # Shutdown the primary once all other replicas are down
    oc delete pod -n "${AIOPS_NAMESPACE}" "${primary}" --ignore-not-found
done
```

Wait for all the Postgres pods to be deleted. All pods are deleted when the following command returns no pods:

```
oc get pod -l k8s.enterprisedb.io/podRole=instance -n ${AIOPS_NAMESPACE}
```

6. (Optional) After the StatefulSets and StrimziPodSets are scaled down, drain the worker nodes.

Run the following command for each of the worker nodes:

```
oc adm drain <node>
```

Where **<node>** is the name of the node to drain.

Note: Some pods, such as storage pods, do not stop because this would violate the disruption budget. If this problem occurs, run the commands in each node until only the storage pods are left, and then stop the command and drain the next node.

5. Shut down the cluster

1. Shut down all the worker nodes on the cluster.
2. Shut down all the master nodes on the cluster.
3. Shut down the API node on the cluster.

For more information about shutting down your cluster nodes, see step 4 in the Red Hat OpenShift documentation Shutting down a cluster gracefully.

6. Restart the cluster

1. Re-export the environment variables that you saved in step 1.1.
2. Restart the cluster nodes in the following order:
    1. Restart the API node.
    2. Restart the master nodes. Check whether all master nodes are in **ready** status by running the following command:

        ```
        oc get nodes
        ```

    3. Restart the worker nodes. Check whether all worker nodes are in **ready** status by running the following command:

        ```
        oc get nodes
        ```

3. After all the nodes are up, uncordon the worker nodes.

    Run the following command for each of the worker nodes:

    ```
    oc adm uncordon <node>
    ```

    Where **<node>** is the name of the node to uncordon.

7. Scale up the workloads

Scaling up the workloads in the following order helps to minimize startup time and resource contention issues.

1. Scale the events operator back up.

    ```
    oc scale deployment --replicas=1 $(oc get deployment -o custom-columns=NAME:.metadata.name --no-headers -n
    ${AIOPS_NAMESPACE}  | grep '^ibm-events-operator-') -n ${AIOPS_NAMESPACE}
    ```

2. Check whether the Kafka and Zookeeper pods are running again. This can take a few minutes.

    ```
    oc get pod -l ibmevents.ibm.com/controller=strimzipodset -n ${AIOPS_NAMESPACE}
    ```

    Example output when the Kafka and Zookeeper pods are running:

    ```
    NAME                                  READY   STATUS    RESTARTS   AGE
    iaf-system-kafka-0                    1/1     Running   0          13d
    iaf-system-kafka-1                    1/1     Running   0          13d
    iaf-system-kafka-2                    1/1     Running   0          13d
    iaf-system-zookeeper-0                1/1     Running   0          13d
    iaf-system-zookeeper-1                1/1     Running   0          13d
    iaf-system-zookeeper-2                1/1     Running   0          13d
    ```

3. You need to scale up each of the StatefulSets to the number of replicas as noted in step 3.2.
    1. Scale up Cassandra, Elasticsearch, and Spark StatefulSets in the following order:
        - aiops-topology-cassandra
        - aiops-ibm-elasticsearch-es-server-all
        - aiops-ir-analytics-spark-worker

        Run the following command to scale up each StatefulSet:

        ```
        oc scale statefulsets <statefulset> --replicas=<number of replicas> -n ${AIOPS_NAMESPACE}
        ```

        Where:

        - **<statefulset>** is the StatefulSet to be scaled up
        - **<number_of_replicas>** is the number of replicas the StatefulSet it to be scaled up to

        For example,

        ```
        oc scale statefulsets aiops-topology-cassandra --replicas=1 -n cp4aiops
        ```

        Note: If IBM Cloud Pak for AIOps is deployed on a multi-zone architecture, then there are multiple **Elasticsearch** StatefulSets with numbered zone names. Each **Elasticsearch** StatefulSet must be scaled up during this step.

    2. Scale the Flink deployments in the following order:
        - aiops-ir-lifecycle-flink
        - aiops-ir-lifecycle-flink-taskmanager
        - aiops-lad-flink
        - aiops-lad-flink-taskmanager

        Note: If you have a base deployment, then do not scale up **aiops-lad-flink** and **aiops-lad-flink-taskmanager**.

        Run the following command to scale up the Flink deployments:

        ```
        oc scale deployment <flink_deployment> --replicas=<number of replicas> -n ${AIOPS_NAMESPACE}
        ```

        Where **<flink_deployment>** is the name of the Flink deployment.

    3. Scale the following StatefulSets in the specified order:

- aiops-ir-core-ncoprimary
- aiops-ir-core-ncobackup
- c-example-couchdbcluster-m
- ${AIOPS_INSTANCE}-redis-server
- aimanager-ibm-minio
- zen-minio

Run the following command to scale up each StatefulSet:

```
oc scale statefulsets <statefulset> --replicas=<number of replicas> -n ${AIOPS_NAMESPACE}
```

Where:

- `<statefulset>` is the StatefulSet to be scaled up
- `<number_of_replicas>` is the number of replicas the StatefulSet it to be scaled up to

4. Scale up the operator deployments.

```
oc scale deployment -l olm.owner.kind=ClusterServiceVersion -n ${AIOPS_NAMESPACE} --replicas=1
```

8. Validate the installation

Note: After a complete cluster restart, it might take approximately an hour for the installation to start running again.

Run the describe command:

```
oc describe installations.orchestrator.aiops.ibm.com -n "${AIOPS_NAMESPACE}"
```

Review the `ComponentStatus` fields to confirm that all components are marked as `Ready` and the phase is `Running`.

Secure Tunnel (IBM Cloud Pak for AIOps on OpenShift)

A Secure Tunnel provides endpoint-to-endpoint connections across a hybrid network without opening firewall rules in an enterprise network. It allows access between different networks through TCP over HTTPS technology.

It can be applied in many use scenarios, such as MCMP, Runbooks, Infrastructure Automation, Slack integrations for IBM Cloud Pak for AIOps, Instana, and Turbonomic.

The traffic through these connections is encrypted with HTTPS. A Secure Tunnel can control access to resources between different networks, with more granular control, and collect all the operations and traffic logins in audit records.

It is not necessary to modify any access rules and firewall configuration between existing infrastructure if you use a Secure Tunnel. It is like a traditional VPN, bridging two networks between the **Secure Tunnel server** and the **Secure Tunnel Connector**.

To learn more about Secure Tunnel, see the following sections:

- Terminology
- Architecture
- Security
- Certificate expiration and renewal
- How to use Secure Tunnel

Terminology

To manage a tunnel connection, you need to understand the following concepts:

- **Secure Tunnel** a group of microservices that include the following services:
  - **UI Server**
    - Used to provide the static resources of the **Secure Tunnel console** and to handle some UI logic.
  - **API Server**
    - Verifies and processes the user's operation request that comes from the **Secure Tunnel console**. The server operates the **Secure Tunnel Custom Resources(CRs)** according to the request.
  - **Controller**
    - Used to monitor updates to the **Secure Tunnel Custom Resources(CRs)** and to take actions according to the CR updates.
  - **Tunnel Connection**
    - The configuration data for bridging two networks.
  - **Application mapping**
    - The configuration data used to control:
      - which applications on the network of the **Secure Tunnel** side can be accessed by the **Secure Tunnel Connector** side and vice versa.
    - The **Tunnel Connection worker** and **Secure Tunnel Connector** use this data to control the access to applications.
  - **Tunnel Connection worker**
    - The instance of the **Tunnel Connection** is created on one or more **Tunnel Connection worker** pods. This worker is also the server side of a TCP-over-HTTPS tunnel. Based on the OSS project.
  - **Secure Tunnel Connector**
    - The other side of a TCP over HTTP tunnel is installed on the peer network of the **Secure Tunnel** to bridge the network where the **Secure Tunnel** is installed. It is based on the OSS project.

Architecture

You can use the following examples of Secure Tunnel to act as a bridge in your enterprise environments.

- **Cloud hosted cluster to On-premise resource**: The cluster is hosted in the cloud and connects to a host in your on-premises system. An example of this is OpenStack connection. For more information, see OpenStack connection.

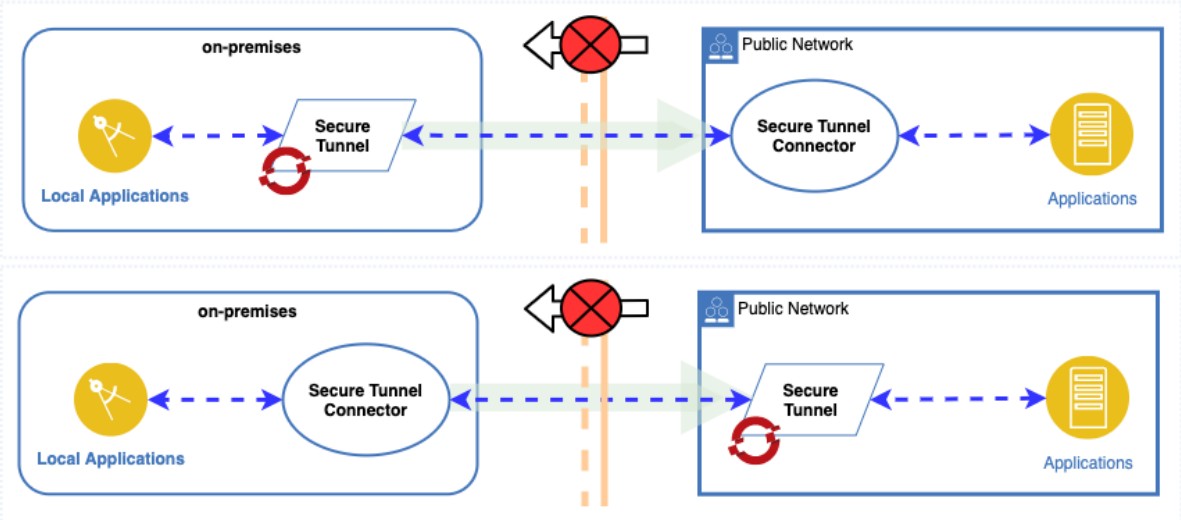

Figure. High-level design

- **Cloud hosted resource to On-premise cluster**: If your Cloud Pak for AIOps instance is installed in on-premises (enterprise network), then you can open the Cloud Pak for AIOps instance to the public network by creating a Secure Tunnel. This is the case where you want to connect to a public resource, such as Slack or Microsoft Teams. An example of this is ChatOps connection. For more information, see ChatOps connection.
- **Bridge two private networks through a third**: You can use Secure tunnel to act as a bridge from one network to another network through a third network. An example of this is the Turbonomic connection. For more information, see Turbonomic connection.

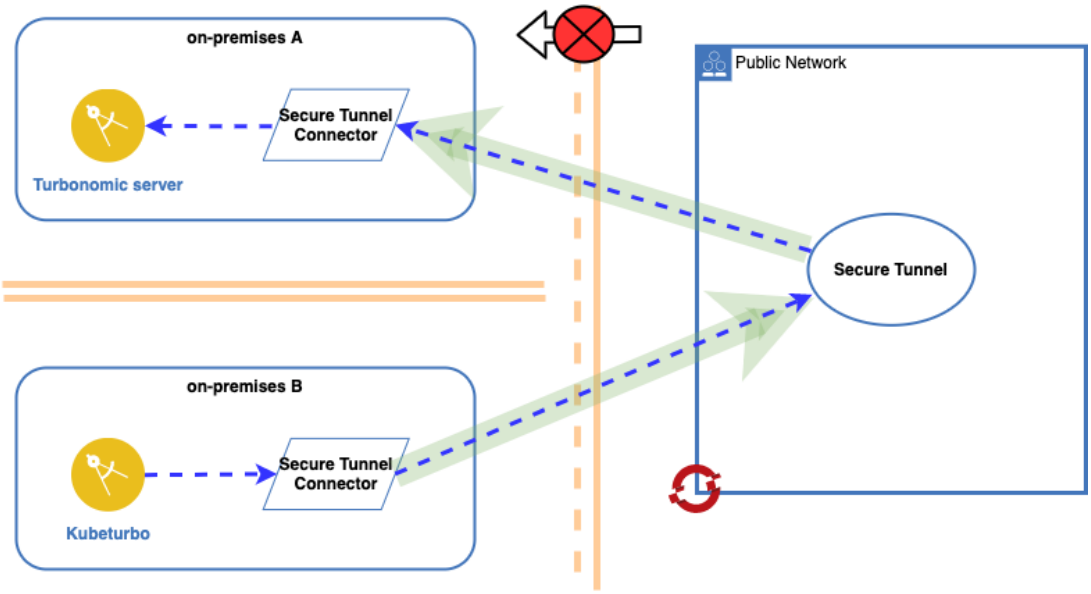

Figure. High-level design for Turbonomic

Features

- Like a traditional VPN, Secure Tunnel can bridge two or more networks. Unlike VPN, it provides more fine-grained resource control.
- **Authentication and authorization** with the IBM Cloud Pak for AIOps console or Red Hat OpenShift Container Platform OAuth and RBAC system.
- Provides two user interfaces
  - **Secure Tunnel console**: A customer can configure a **Secure Tunnel Connection** and control which applications can be accessed by the peer network from the console UI.
  - **Command line**: An automation script can configure a **Secure Tunnel Connection** and control which applications can be accessed by the peer network by using the `kubectl` or `oc` command line tools to operate the CRs of the **Secure Tunnel**.
- The connection is encrypted with Mutual Transport Layer Security(mTLS).
- Based on OSS project.

High-Level Design

- **Secure Tunnel** can be installed from the **Operator Hub** of the Red Hat OpenShift Container Platform console.
- **Secure Tunnel Connector** can be installed on a Red Hat OpenShift Container Platform cluster, Kubernetes (such as IBM Kubernetes Service) or a host machine (VM or physical machine).
- It can bridge the network on the **Secure Tunnel** side and the network on the **Secure Tunnel Connector** side through a WebSocket connection between the **Secure Tunnel** and **Secure Tunnel Connector** with mTLS authentication.

You can use the **Secure Tunnel console** or **command line tools** to control:

- which applications on the network of the **Secure Tunnel** side can be accessed by the **Secure Tunnel Connector** side.
- which applications on the network of the **Secure Tunnel Connector** side can be accessed by the **Secure Tunnel** side.

Security

The following security measures make Secure Tunnel a safe tool to use.

- **Authentication**
  - IBM Cloud Pak for AIOps console accesses the Tunnel Connection worker with JWT authentication token.
  - The Connector is authenticated with Mutual Transport Layer Security (mTLS).
- **Access control**
  - Only IBM Cloud Pak for AIOps console users with the `Automation Adminstrator` or `Administrator` role can use Secure Tunnel.
  - For more information about users and roles, see Managing user access control.
- **Data encryption in communication**
  - All traffic from out-cluster (Connector or console) is transported by HTTPS.
  - All application mapping traffic are encrypted by TCP over HTTPS.
- **Auditing**
  - All configuration changes (tunnel connection or application mapping) are stored in the log system for auditing. For more information, see Configuring tunnel audit logs.
  - All connections are stored in the log system for usage metrics and auditing.

Certificate expiration and renewal

If you renew the Secure Tunnel TLS certificate or it expires and the IBM Certificate Manager renews it, then the Secure Tunnel worker server automatically reloads the renewed certificate. However, the Secure Tunnel connector does not automatically reload the renewed certificate. You must download a new Secure Tunnel connector installation script, and then uninstall and reinstall the Secure Tunnel connector. For more information, see the instructions in Install the Secure Tunnel Connector.

How to use Secure Tunnel

- To create a Secure Tunnel for an integration, see Creating Secure Tunnel Connections.
- To copy the application mapping URL that can be accessed by an integration, or view the configuration details and status of all tunnel connections and application mappings, see Viewing Secure Tunnel.
- To modify configurations for a Secure Tunnel, see Modifying Secure Tunnel.
- To audit Secure Tunnel operations and connections, see Auditing Secure Tunnel.

Installing Secure Tunnel

Use the following instructions to help you install Secure Tunnel for use with IBM Cloud Pak for AIOps.

Two methods are avilable to activate Secure Tunnel for use with IBM Cloud Pak for AIOps:

- Install Secure Tunnel from IBM Cloud Pak for AIOps
- Install Secure Tunnel without IBM Cloud Pak for AIOps (as a stand-alone component) to your Red Hat OpenShift cluster

Install Secure Tunnel from IBM Cloud Pak for AIOps

1. Ensure that IBM Cloud Pak for AIOps is installed.
2. An IBM Cloud Pak for AIOps console user with the `Automation Administrator` or `Administrator role` is needed to use Secure Tunnel. For more information about users and roles, see Managing user access control.
3. If you want to use Secure Tunnel to integrate with Slack or Microsoft Teams, you need to create a Slack integration or a Microsoft Teams integration on the IBM Cloud Pak for AIOps console. For more information, see Creating Slack integrations and Microsoft Teams integrations.
4. The Secure Tunnel component is not enabled by default at IBM Cloud Pak for AIOps installation time. Before you use Secure Tunnel, you need to enable the Secure Tunnel component.

   Two methods are available for enabling Secure Tunnel.

   - Console method:

- Access Red Hat® OpenShift® Container Platform console.
- Click **Operators** > **Installed Operators**.
- Select **IBM Cloud Pak for AIOps** operator, and locate the **IBM Cloud Pak for AIOps** instance.
- Set **Enable Secure Tunnel** to `true` to install Secure

- YAML method:
  - Access Red Hat® OpenShift® Container Platform console.
  - From your Red Hat OpenShift console, click **Operators** > **Installed Operators**.
  - From the **Project** menu, select the project where you created the **IBM Cloud Pak for AIOps** instance.
  - Select **IBM Cloud Pak for AIOps** operator, and locate the **IBM Cloud Pak for AIOps** instance.
  - Click **Installation Item**. Switch to the **YAML** view, and update the YAML file by changing the field of `enableConnectionModule` from `false` to `true`.

    ```
    spec:
      enableConnectionModule: true
    ```

    Note: If you cannot find the connection and enabled fields in the YAML file, you need to add them to the YAML file manually.
  - Ensure that all Secure Tunnel pods are in running state by running the following command:

    ```
    oc -n <namespace> get pod | grep tunnel
    ```

    Where `<namespace>` is the IBM Cloud Pak for AIOps namespace.

    The command result can resemble the following example:

    ```
    NAME                                              READY   STATUS    RESTARTS   AGE
    ibm-secure-tunnel-operator-677c7b4b7-gqjbg        1/1     Running   0          150m
    sre-tunnel-controller-7b9d59957b-rkxp7            1/1     Running   0          147m
    sre-tunnel-tunnel-network-api-985df588c-z6m4z     1/1     Running   0          147m
    sre-tunnel-tunnel-ui-mcmtunnelui-56c744598-qhlfw  1/1     Running   0          147m
    ```

5. **(Optional) Enable EgressNetworkPolicy**: There is no egress firewall policy defined when you install Secure Tunnel, so outgoing traffic from workload pods to the internal and external network is unrestricted. If you require a more secure environment, complete the following steps:

   1. Go to your **OpenShift console** > **Operators** > **Installed Operators** > **IBM Secure Tunnel** > **Tunnel** > **sre-tunnel** > **YAML**.
   2. Add the following configuration to the YAML of the Tunnel CR to enable the egress NetworkPolicy:

      ```
      spec:
        enableEgressNetworkPolicy: true
        ...
      ```

      Note: This feature only supports Red Hat OpenShift Container Platform version 4.10 and above, and ensures there are not any restrictive EgressNetworkPolicies in place.

6. The Secure Tunnel Connector can be installed to both a cluster (OpenShift or IBM Kubernetes Service cluster) or a host machine (virtual machine or physical machine). Depending on which method you use, make the following preparations.

   - **If you want to install the Connector in a cluster (OpenShift or IBM Kubernetes Service cluster)**:
     - Ensure that the following minimum resource requirements are met:
       - 1 vCPU
       - 1 GB random access memory (RAM)
     - Ensure that you can access the cluster from a public network. The cluster domain name needs to be resolved by a public DNS.
     - Ensure that the cluster has a *CA-signed TLS certificate* so that the verification handshake of the Slack server or the Microsoft Teams server can be successful. A self-signed TLS certificate does not work for a Slack connection.
   - **If you want to install the Connector in a host machine (virtual machine or physical machine)**:
     - Ensure that the following minimum resource requirements are met:
       - 1 CPU
       - 1 GB random access memory (RAM)
     - Ensure that Podman is installed, and running on the virtual machine or physical machine.
     - If this is used to integrate with the Slack or MS Teams. You need to meet the following extra conditions:
       - Ensure that you can access the host machine from a public network. The hostname needs to be resolved by a public DNS.
       - Ensure that a CA-signed TLS certificate is available. This is used when you create the ChatOps connection.

         Note: If you have an IBM Cloud account, see Getting started with IBM Cloud Internet Services to apply for a **DNS name**, and see Preparing to order public certificates to apply for a CA-signed certificate. Extract the CA-signed certificate file, `hostname.pem`, for the certificate and `hostname.key` for the private key. If an intermediate file is in your CA-signed certificate file – such as hostname-intermediate.pem – concatenate this file with a cert file, such as hostname.pem, by running the following command:

         ```
         cat hostname-intermediate.pem >> hostname.pem
         ```

Install Secure Tunnel without IBM Cloud Pak for AIOps (as a stand-alone component) to your OpenShift cluster

1. Ensure that your cluster meets the following requirements:

- Supported Red Hat OpenShift Container Platform versions
- Hardware requirements: Ensure that the following minimum resource requirements are met:
  - 2 vCPU
  - 2 GB random access memory (RAM)

2. Create the catalog source with the OpenShift console

   1. Log in to your Red Hat OpenShift cluster's console.

   2. Add the IBM Operators CatalogSource. Click the **plus icon** in the upper right corner to open the *Import YAML* dialog box. Paste in the following content, and then click **Create**:

      ```
      apiVersion: operators.coreos.com/v1alpha1
      kind: CatalogSource
      metadata:
        name: ibm-aiops-catalog
        namespace: openshift-marketplace
      spec:
        displayName: ibm-aiops-catalog
        publisher: IBM Content
        sourceType: grpc
        image: icr.io/cpopen/ibm-aiops-
      catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
      ```

   3. Go to **Administration** > **Cluster Settings**. Under **Global Configuration** > **OperatorHub** > **Sources**, verify that the `ibm-aiops-catalog` CatalogSource object is present.

      Note: For more information, see Catalog Sources

3. Install the Secure Tunnel operator with the Red Hat OpenShift console

   1. Log in to your Red Hat OpenShift cluster's console.
   2. Click **Operators** > **OperatorHub**. The *OperatorHub* page is displayed.
   3. In the *All Items* field, enter **IBM Secure Tunnel**. The Secure Tunnel operator is displayed.
   4. Click the **IBM Secure Tunnel** tile. The **IBM Secure Tunnel** window is displayed.
   5. Click **Install**. The *Install Operator* page is displayed.
   6. Enter the following values:
      1. Set the **Installation mode** to **All namespaces on the cluster(default)**.
      2. Set **Update Channel** to **v4.8**.
      3. Set **Approval Strategy** to **Automatic**.
   7. Click **Install** and wait for the Secure Tunnel operator to install.
   8. Verify that the IBM Cloud Pak for AIOps operator is successfully installed.
      1. Navigate to **Operators** > **Installed Operators**, and select your project from the *Projects* dropdown. Secure Tunnel operator in the project is listed with a status of *Succeeded*.

4. Install Secure Tunnel

   1. To create a Secure Tunnel project (namespace) with the Red Hat OpenShift console From your Red Hat OpenShift console, click **Home** > **Projects**. Select **Create Project**, specify the name of the project that you want to create (for example `tunnel-stand-alone`) and click **Create**.

      Note: For more information, see Namespace.

   2. Create the entitlement key secret with the Red Hat OpenShift console. Complete the following steps to create a docker-registry secret to enable your deployment to pull the Secure Tunnel images from the IBM® Entitled Registry:

      1. Obtain the entitlement key that is assigned to your IBMid. Log in to MyIBM Container Software Library with the IBMid and password details that are associated with the entitled software.

      2. In the *Entitlement key* section, select **Copy key** to copy the entitlement key to the clipboard.

      3. From your Red Hat OpenShift console, click **Workloads** > **Secrets**.

      4. From the **Project** menu, select the **project** that you created earlier in **Create a Secure Tunnel project (namespace)**.

      5. Click the **Create** button, and select Image Pull Secret from the menu. The Create Image Pull Secret form is displayed. Enter the following values and then click **Create**.

         - **Secret Name:** `secure-tunnel-pull-secret`
         - **Authentication Type:** Image Registry Credentials
         - **Registry Server Address:** `cp.icr.io`
         - **Username:** `cp`
         - **Password:** Use the entitlement key that you copied earlier.

      Note: For more information, see Entitlement Keys

   3. Create an instance of the Secure Tunnel with the Red Hat OpenShift console. Secure Tunnel is supported by namespace isolation, so you can create multiple Secure Tunnel instances in different namespaces, for different users. Secure Tunnel also uses the Red Hat OpenShift OAuth&RBAC for authentication and authorization. You can configure the permissions for each Secure Tunnel instance user.

      1. From your Red Hat OpenShift console, click **Operators** > **Installed Operators**.

      2. From the **Project** menu, select the project that you want to create the Secure Tunnel instance in. Use the project that you created earlier in **Create a Secure Tunnel project (namespace)**.

      3. Select **IBM Secure Tunnel** operator.

      4. Click **Create Installation** on the **Tunnel** box. The default **Form View** is displayed. Enter the following values:

- **Name:** Specify the name that you want your Secure Tunnel instance to be called.
- **License:** Expand the *License* section and read the agreement. Toggle the *License Acceptance* switch to *True* to accept the license.
- **Image Pull Secret:** Select the `secure-tunnel-pull-secret` secret that you created in the step **Create the entitlement key secret**.
- **runAsStandAlone**: If the **IBM Certificate manager** is not installed in your environment. Toggle this switch to **True** and it will create the TLS Certificate that is used by the Secure Tunnel without the **IBM Certificate manager**.
- **Size:** Select the size that you require for your Secure Tunnel installation.
- **Audit Receiver:** Refer to the audit log guide
- (Optional) **Enable EgressNetworkPolicy:** There is no egress firewall policy defined when you install Secure Tunnel, so outgoing traffic from workload pods to the internal and external network is unrestricted. If you require a more secure environment, toggle this switch to `True` to enable the egress NetworkPolicy. ***Note:** This feature only supports Red Hat OpenShift Container Platform version 4.10 and above, and ensures there are not any restrictive EgressNetworkPolicies in place.

Refer below to the tunnel parameters with their description, variable type and default values.

Tunnel Settings

Parameter	Description	Default value	Type
size	The sizing of the Secure Tunnel. Supported values: `small`, `medium`, `large`. `small`: replica is 1 for all operands, no HA; `medium`: replica is 3 with HA enabled; `large`: replica is 3 with HA enabled and with extra capacity for CPU/memory.	small	String
license.accept	Expand the License section and read the agreement. Toggle the License Acceptance switch to True to accept the license.	false	Boolean
uiReplicas	The replicas of the UI server pods.	Depends on size	int
apiReplicas	The replicas of the API server pods.	Depends on size	int
controllerReplicas	The replicas of the controller server pods.	Depends on size	int
workerReplicas	The replicas of the worker server pods per tunnel connection.	Depends on size	int
pullSecret	The pull secret of the Secure Tunnel images.	secure-tunnel-pull-secret	String
runAsStandAlone	If you want to install the Secure tunnel without IBM Cloud Pak for AIOps, toggle this to True	false	Boolean
showInContainerLog	Show audit logs in the container log.	true	Boolean
auditReceiver.mongoDB.mongoAddress.name	The name of the audit log MongoDB receiver.	null	String
auditReceiver.mongoDB.mongoAddress.mongoAddress	The audit log MongoDB receiver address. Example: `<IP>:27017`	null	String
auditReceiver.mongoDB.mongoAddress.passwordSecretName	The Kubernetes secret that contains the audit log MongoDB receiver login username and password. Create it in the Secure Tunnel namespace. It should contain "user" and "password" data items.	null	String
auditReceiver.mongoDB.mongoAddress.mongoDatabaseName	The database name of the audit log MongoDB receiver	null	String
auditReceiver.mongoDB.mongoAddress.tlsSecret The tls Kubernetes secret name of the audit log MongoDB receiver. Create it in the Secure Tunnel namespace. It should contain "ca.crt", "tls.crt" and "tls.key".	null	String	
auditReceiver.syslog.name	The name of the audit log Syslog receiver.	null	String
auditReceiver.syslog.syslogAddress	The server address of the audit log Syslog receiver.	null	String
defaultTunnelWorkerResources.limits.cpu	The default Tunnel Worker cpu limit.	3000m	String
defaultTunnelWorkerResources.limits.memory	The default Tunnel Worker memory limit.	3072Mi	String
defaultTunnelWorkerResources.requests.cpu	The default Tunnel Worker cpu requests.	100m	String
defaultTunnelWorkerResources.requests.memory	The default Tunnel Worker memory requests.	128Mi String	
applicationMappingPortRang	Application Mapping listen port range. For example: 30000-65000	30000-65000	String
enableEgressNetworkPolicy	If you require a more secure Secure Tunnel environment you can enable this item. Then it will create the egress network policy automatically. Note: This only works on Red Hat OpenShift 4.10 or later.	false	Boolean
connectionTLSCertDurationTime	By default, the TLS certificate that is used by the Tunnel connection. Duration time is 87600h0m0s(10 years). Update this item if you want to change the duration time.	87600h0m0s(10 years)	String

5. Click **Create**. This creates the Secure Tunnel instance.

6. After a few minutes, select the project that you specified for your Secure Tunnel instance from the **Project** menu. Navigate to **Operators** > **Installed Operators** > **IBM Secure Tunnel** and then click the **Tunnel** tab. Under **Installations**, look for the entry with the name that you specified for your Secure Tunnel instance, and verify that it has a *Status* of **Phase: Running**.

7. Refer to: Production installation

Note: One project(namespace) can only create one Secure Tunnel instance.

5. Access the Secure Tunnel console:
    1. From your Red Hat OpenShift console, click **Networking** > **Routes**.
    2. From the **Project** menu, select the project where you created the **Secure Tunnel** instance.
    3. Select the **sre-tunnel-tunnel-ui**.
    4. Click the url of the **Location**. The Secure Tunnel console opens. Log in with your Red Hat OpenShift Username and password.

Uninstalling Secure Tunnel

- **If the Secure Tunnel was installed from IBM Cloud Pak for AIOps**, complete the following steps to disable it.
    1. From your Red Hat OpenShift console, click **Operators > Installed Operators**.
    2. From the **Project** menu, select the project where you created the **IBM Cloud Pak for AIOps** instance.
    3. Select the **IBM Cloud Pak for AIOps operator, and locate the **IBM Cloud Pak for AIOps** instance.
    4. Click **Installation Item**. Switch to the **YAML** view, and update the YAML file by changing the `enableConnectionModule` value for the connection from `true` to `false`.

        ```
        spec:
          enableConnectionModule: false
        ```

- **If the Secure Tunnel was installed from the Operator hub as stand-alone**, complete the following steps to uninstall it.
    1. From your Red Hat OpenShift console, click **Operators > Installed Operators**.
    2. From the **Project** menu, select the project where you installed the **IBM Secure Tunnel**.
    3. Select **IBM Secure Tunnel** operator, and locate the Tunnel instance.
    4. Delete the *sre-tunnel* (by default) instance of the Tunnels.
    5. Uninstall the IBM Secure Tunnel operator from **Operators > Installed Operators**.

Note: There can be some resources, such as the CRDs and TLS cert secret of the secure tunnel that will not be deleted. If you want to completely clear them, you can download the `uninstall-secure-tunnel.sh` and run command `./uninstall-secure-tunnel.sh -n <the namespace of the secure tunnel>` to do that.

Install the Secure Tunnel Connector

Install the Secure Tunnel Connector for the network being connected to a cluster, Red Hat® OpenShift® on IBM Cloud® service (ROKS) cluster, or a host machine (VM or physical). With the Secure Tunnel Connector installed you can establish a secure tunnel between the network of the cluster where you installed the **Secure Tunnel** (server), such as your IBM Cloud Pak for AIOps cluster, and the cluster where you installed the **Secure Tunnel Connector**.

Important Depending on how you plan to create your Secure Tunnel connection, the Secure Tunnel Connector can be installed automatically. For instance, if you are connecting IBM Cloud Pak for AIOps to a Red Hat OpenShift Container Platform cluster for a ChatOps application, the Secure Tunnel Connector can be installed automatically. For more information, see Creating a Secure Tunnel connection.

Note: If your Secure Tunnel server is installed on an OpenShift cluster with a domain name that is not resolvable from DNS, then Secure Tunnel might not be able access it through the OpenShift URL. So you might find that the Tunnel Connector fails to connect to the Secure Tunnel server. You need to log in to the host machine, on which Tunnel Connector is installed, and add the IP and domain (for example, 9.30.111.xxx console-openshift-console.apps.test.cp4waiops.com) to `/etc/hosts` to resolve all the domain names. Follow these steps:

1. Login to the host machine on which Tunnel Connector is installed.
2. Find out all the domain names to be added, run this command in the `tunnel-connector-install-scripts` directory

    ```
    cat install-connector.sh | grep "-e SERVER=" | head -n 1
    ```

    You find outputs like this:

    ```
    SERVER='https://r8b74ff6d23d84fd50-cp4waiops.apps.svt-airgap-1.svt.cp4waiops.com/sre-tunnel-
    tunnel/ws;https://r8b74ff6d23d84fd51-cp4waiops.apps.svt-airgap-1.svt.cp4waiops.com/sre-tunnel-
    tunnel/ws;https://r8b74ff6d23d84fd52-cp4waiops.apps.svt-airgap-1.svt.cp4waiops.com/sre-tunnel-tunnel/ws;' \,
    ```

3. Add each domain in the output to the `/etc/hosts` with the IP address of your OpenShift cluster(for example `9.30.111.xxx r8b74ff6d23d84fd50-cp4waiops.apps.svt-airgap-1.svt.cp4waiops.com`)
4. If you already installed Tunnel Connector before doing these steps, then you need to restart Tunnel Connector by using the command `podman restart <the container id>`.
5. If you completed the above steps and the tunnel connection console UI displays the **Ready** status, but your application, which is using the Secure tunnel, still does not work, check whether you added all domains to `/etc/hosts`.
6. If you selected `Cloud` when creating the Tunnel Connector, then you need to re-create the Tunnel Connector, select `Host machine`, then download the Tunnel Connector installation package and install it to a host machine.

Prerequisites

Download the Secure Tunnel Connector installation scripts:

- From the console, go to **Manage connections**, locate the tunnel connection name, and click **Action** > **Install Connector**.
- Obtain the installation package **`tunnel-connector-install-scripts.tar.gz`** by clicking **Download**. Or you can click **Copy**, and then run the copied commands on a Linux system.

  Note: The installation script is for only a specific **Secure Tunnel Connection**, and cannot be used for other Secure Tunnel Connections.

Installing the Secure Tunnel connector to a cluster

1. Transfer the installation package **`tunnel-connector-install-scripts.tar.gz`** to a virtual machine where you can log in and access the cluster where you want to install the Connector.

   Note: Ensure that the OpenShift **`oc`** or **`kubectl`** tool is installed in the virtual machine.

2. Log in to to the cluster on the virtual machine with the **`oc login`** command, and unpack the installation package.
3. Create the project (namespace) where you want to install the Connector.
4. Unpack the **`tunnel-connector-install-scripts.tar.gz`** package.
5. Change to the **`tunnel-connector-install-scripts`** directory.
6. Run the following command to install the Connector:

   ```
   ./install-connector.sh --namespace <namespace> --accept-license true
   ```

7. Verify whether the Connector is installed by running the following command:

   ```
   oc get po -n <namespace>
   ```

Installing the Secure Tunnel connector to a host machine (virtual machine or physical machine)

1. Transfer the installation package **`tunnel-connector-install-scripts.tar.gz`** to the virtual machine where you want to install the **`Connector`**.
2. Log in to the virtual machine and unpack the installation package.
3. Install Podman on the virtual machine.

   Note: Docker is not shipped or supported for Red Hat Enterprise Linux (RHEL) 8. The Podman container engine replaced docker as the preferred, maintained, and supported container runtime of choice for Red Hat Enterprise Linux 8 systems. For more information, see Running containers without Docker in the Red Hat documentation.

4. Unpack **`tunnel-connector-install-scripts.tar.gz`**.
5. Change to the **`tunnel-connector-install-scripts`** directory.
6. Run the **`./install-connector.sh`** script to install the Connector on the virtual machine. Accept the license agreement when prompted to start the installation. Alternatively, you can accept the license by adding the **`--accept-license true`** parameter on the command line.
7. When the script finishes, verify that the Connector is installed by running the following command:

   ```
   podman ps
   ```

Installing more than one Secure Tunnel Connector to a host machine

If you want to install more than one Secure Tunnel Connector:

- Ensure they are from a different Secure Tunnel server or different IBM Cloud Pak for AIOps instance. If they are from the same Secure Tunnel server or IBM Cloud Pak for AIOps instance, you just need to add another ApplicationMapping to one **Tunnel Connection** instead of creating another **Tunnel Connection** and installing another **Tunnel Connector**.
- Configure each Secure Tunnel operator to add the **`applicationMappingPortRang: 30000-65000`** item to the **`YAML`**. The **`applicationMappingPortRang`** should be different for each Secure Tunnel. For example, the first one should be **`30000-40000`** and the second should be **`40001-50000`**. Follow these steps to configure the **`applicationMappingPortRang`**:

  1. From the Red Hat OpenShift Container Platform console, click **Operators** > **Installed Operators**.
  2. From the **Project** dropdown menu, select the project in which you created the Secure Tunnel instance.
  3. Click the **IBM Secure Tunnel** > **Tunnel** tab > click the existing **sre-tunnel** instance > change to **YAML** tab.
  4. Add **`applicationMappingPortRang: 30000-65000`** to the YAML and save it. The final YAML should look like:

```
spec:
  license:
    accept: true
  version: 1.0.0
  pullSecret: secure-tunnel-pull-secret
  showInContainerLog: true
  runType: production
  size: small
```

```
controllerReplicas: 1
applicationMappingPortRang: 30000-65000
```

The Secure Tunnel Connector container runs in the host network on host machines. Avoid port conflicts if you install multiple Secure Tunnel Connectors in the same host machine. For the following reasons, do not use port numbers **9000**, **50443** or **12443**

- Secure Tunnel Connector container listens on port **9000** for health check by default.
- The Secure Tunnel Connector container in a *private network to public network connector* setup connects to the Secure Tunnel server on port **50443** by default.
- Secure Tunnel Connector container for **Slack** and **Microsoft Teams** listens on port **12443** on **Exposed mapping port** by default.
- When you create a **Secure Tunnel Connection** from a **Custom** template and select **Secure Tunnel in private network initializes connection to connector in public network** in the **Direction** page, and select **Host machine** in the **Connector settings** page you must input a different port number than **50443** for your connection. And this port number must be different than the port number for all the connectors that run on the same host machine.

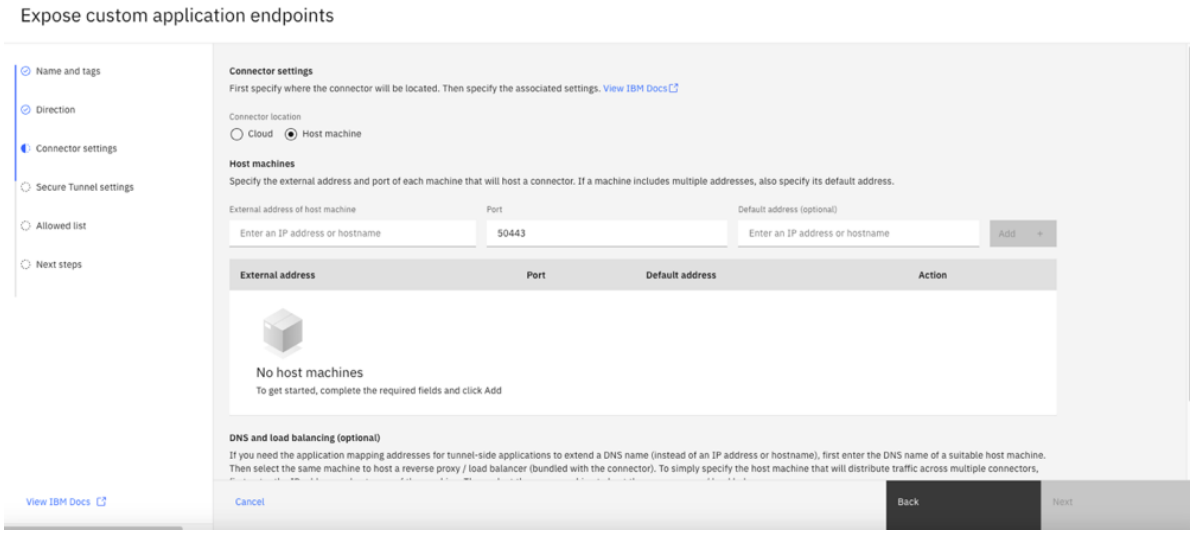

Figure. Port configuration

- When you create a **Secure Tunnel Connection** from the **ChatOps** template, and select **Host machine** in the **Connector settings** page you must input a different port number than **50443** in the **Port** field and a different port number to **12443** in **Exposed mapping port** field. These port numbers must be different than the port numbers for all the connectors you are running on the same host machine.

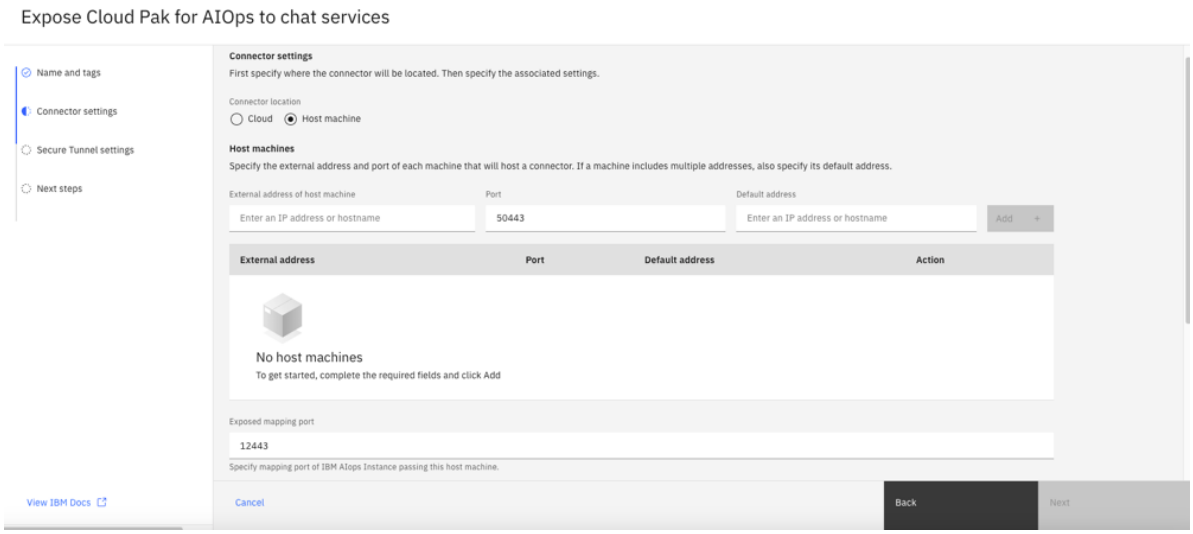

Figure. Port configuration

- When you complete creating the connection, you can download and transfer the installation package to the host machine on which a Secure Tunnel connector is already installed.
- When you install the connector you must specify a different health check port to **9000** and the other health check ports used by other secure tunnel connectors that run on this host machine. Use this command to assign a specific **<port number>**,

```
./install-connector.sh --accept-license true --port <port number>
```

Note: For Port conflicts **install-connector.sh** uses **fuser** to check port conflicts during installation. If you do not have **fuser** installed on the host machine, **install-connector.sh** might miss some conflicts. If it does, your connector container might fail to start.

You can check the Secure Tunnel Connector container log by running the following command.

`podman logs <container id>`

where **<container id>** is the id of the container.

- If you find a port conflict on the health check port in the container log:
    1. Uninstall the container by using the command

       `./uninstall-connector.sh`

    2. Reinstall the connector with a different health check port. For example, `./install-connector.sh --accept-license true --port 9002`
- If you find a port conflict on the port that is used to connect the Secure Tunnel server and/or on the **Exposed mapping port**, then
    1. Uninstall the container by using the command:

       `./uninstall-connector.sh`

    2. Delete the Secure Tunnel connection from the web UI.
    3. Create a new Secure Tunnel connection with different ports and try again.

For more information, see Troubleshooting Secure Tunnel.

Optional: Uninstalling the Secure Tunnel Connector

Use the script to uninstall the **Secure Tunnel Connector**:

1. Download the Connector installation package `tunnel-connector-install-scripts.tar.gz`
    1. From the console, go to **Manage connections**, locate the tunnel name.
    2. Under the **Action** column for the tunnel, expand the menu (three dots icon) and click **Install**.
    3. Obtain the installation package `tunnel-connector-install-scripts.tar.gz` by clicking **Download**. Or you can click **Copy**, and then run the copied commands on a Linux system.

       Note: The installation script is for only a specific **Secure Tunnel Connection**, and cannot be used for other Secure Tunnel Connections.
2. Uninstall the Connector from the **Cloud** with the installation package:
    1. Transfer the installation package `tunnel-connector-install-scripts.tar.gz` to a virtual machine on which the OpenShift CLI (`oc`) is installed. Log in and access the **Cloud** where you want to uninstall the Connector.
    2. Log in to the virtual machine and unpack the installation package.
    3. Change to `tunnel-connector-install-scripts` directory
    4. Run `./uninstall-connector.sh` script with parameters like below to uninstall the Connector from the Cloud.

       `./uninstall-connector.sh --namespace <namespace>`
3. Uninstall the Connector from the **host machine** with installation package:
    1. Transfer the installation package `tunnel-connector-install-scripts.tar.gz` to the host machine on which the Connector is installed.
    2. Log in to the virtual machine and unpack the installation package.
    3. Change to `tunnel-connector-install-scripts` directory.
    4. Run `./uninstall-connector.sh` script with the following parameters to uninstall the Connector on the host machine.

       `./uninstall-connector.sh --namespace <namespace>`

Optional: Delete the Secure Tunnel Connector resources after a tunnel connection is deleted

If you deleted a tunnel connection by clicking **Action** > **Delete** in the *Manage connections* page on the IBM Cloud Pak for AIOps console, and you did not uninstall the connector, you can delete the connector resources in the cluster virtual machine or the host machine manually. Otherwise, a new connector cannot be installed on the Cluster virtual machine or the host machine.

- If the connector is running in an Red Hat OpenShift Container Platform cluster or Red Hat OpenShift on IBM Cloud, follow the steps to delete connector resources:
    1. Log in to the Red Hat OpenShift Container Platform cluster or Red Hat OpenShift on IBM Cloud cluster from command line, and then find all connector resources by running the following command:

       ```
       oc get sts,secret,service,role,route -n <your tunnel connector namespace> \
             -l app.kubernetes.io/group=<your release name>-tunnel-connector.app
       ```

    2. You can find the `release name` by checking the tunnel server tunnel prefix of `tunnel-network-api`, like this, which gives the `release name` as `sre-tunnel`:

       ```
       oc get deploy -n cp4aiops | grep tunnel-network-api
           sre-tunnel-tunnel-network-api                          3/3     3            3           142m
       ```

    3. Remove these resources by running this command:

```
for res in $(oc get sts,secret,service,role,route -n <your tunnel connector namespace> \
      -l app.kubernetes.io/group=<your release name>-tunnel-connector.app -o name )
do
oc delete -n <your tunnel connector namespace> $res
done
```

4. If there is no other Tunnel connector installed in the namespace, delete the secret by running the command:

   ```
   oc get secret -n <your tunnel connector namespace> | grep tunnel-connector
   ```

   Note, Do not attempt to delete the secret if the tunnel connectors are still present as the secret might be used by one of the connectors.

Upgrading Secure Tunnel

Use the following instructions to help you upgrade Secure Tunnel either with IBM Cloud Pak for AIOps or as a standalone component.

Two methods are avilable to upgrade Secure Tunnel for use with IBM Cloud Pak for AIOps:

- Upgrading Secure Tunnel from IBM Cloud Pak for AIOps
- Upgrading Secure Tunnel as a stand-alone component in your Red Hat OpenShift cluster

Upgrading Secure Tunnel from IBM Cloud Pak for AIOps

Secure Tunnel is upgraded when you upgrade IBM Cloud Pak for AIOps. For details about upgrading IBM Cloud Pak for AIOps, see Upgrading.

Upgrading Secure Tunnel as a stand-alone component in your Red Hat OpenShift cluster

1. **Configure automatic catalog polling**

   1. Log in to the console for your OpenShift cluster.
   2. Go to **Administration** > **Cluster Settings**.
   3. Click **Configuration**, then scroll down and click **OperatorHub**.
   4. Select **Sources**, then scroll down and click **`ibm-aiops-catalog`**.
   5. Click **YAML** to switch to the YAML view, and if **`spec.image`** is not set to **`icr.io/cpopen/ibm-aiops-catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753`**, then update the YAML to have the following entry in the **`spec`** block, and save it.

      ```
      spec:
        displayName: ibm-aiops-catalog
        publisher: IBM Content
        sourceType: grpc
        image: icr.io/cpopen/ibm-aiops-
      catalog@sha256:58c0082ad5e9de6bc2869b528e847702f6c183a06ac49a82d64ad8efd339f753
      ```

2. **Update the operator subscription**

   Use the following steps to update the *spec.channel* value of the Secure Tunnel subscription to the release that you want to upgrade to.

   1. Log in to the console for your OpenShift cluster.
   2. Select **Home** > **Search**.
   3. From the **Project** list, select the project (namespace) that your Secure Tunnel subscription is deployed in. This is your Secure Tunnel project if your deployment is namespace scoped, or openshift-operators if your deployment has a cluster wide scope.
   4. In the **Resources** list, select **SUB Subscription**. A list of subscriptions is displayed.
   5. Click the subscription that has the name *ibm-secure-tunnel-operator*. A new window with the subscription details for *ibm-secure-tunnel-operator* is displayed.
   6. Click the value for the **Update channel** box. A new window called *Change Subscription update channel* is displayed.
   7. Change the channel to the version that you want and click **Save**.

      If the subscription has been configured with **Manual** for the **Update approval**, then you need to click **Upgrade available** on the **Upgrade status** > **Preview InstallPlan** > **Approve** to approve this upgrade.

      Note: You need to upgrade the channel versions one by one. For example, if your current channel version is 3.7.x, you cannot skip the 4.1.x to change the channel to 4.2.x. You must upgrade it to 4.1.x and then upgrade it to 4.2.x.

3. **Verify the deployment**

   Use the following procedure to check the status of your upgraded Secure Tunnel deployment. It takes around 2-10 minutes for the upgrade to complete (subject to the speed with which images can be pulled).

   1. Log in to the console for your OpenShift cluster.

2. Click **Operators** > **Installed Operators**.
3. From the **Project** list, select the project (namespace) that Secure Tunnel is deployed in if your deployment is namespace scoped, or openshift-operators if your deployment has a cluster-wide scope.
4. Locate **IBM Secure Tunnel** in the list and verify that the annotation shows the version that is required.

Creating Secure Tunnel connections

A Secure Tunnel connection links the network that contains the Secure Tunnel to a remote network. Your applications can be on either side of the connection.

Secure Tunnel comes with connection templates for common application scenarios, including ChatOps, VMware, and Turbonomic. You can also create custom connections to support more scenarios.

- Prerequisites
- Secure Tunnel Web Console
- Creating a secure tunnel
  - ChatOps connection
    - ChatOps connection (Microsoft Azure as host machine)
  - VMware connection
  - Turbonomic connection
  - OpenStack connection
  - Custom connection
    - Creating a custom Instana connection
    - Creating a Secure Tunnel generic webhook connection

Prerequisites

- Ensure that you have Red Hat OpenShift Container Platform installed on one of your networks (referred to as **network-A** in the following steps). You use this instance of OpenShift to bridge to the other network.
- Ensure that another system (Red Hat OpenShift Container Platform, Kubernetes, or other system) or a host machine (virtual machine or physical machine) is available on a different network (referred to as **network-B** in the following steps). You use this network as the location for installing the Secure Tunnel Connector.
- Ensure that the network access is available on **network-A** and **network-B**. Either **network-A** or **network-B** needs to have a public IP address.
- Ensure that you install Secure Tunnel. For more information, see Installing Secure Tunnel.
- Verify that you can access the Secure Tunnel web console.

Secure Tunnel UI

Use either of these methods to access the Secure Tunnel UI:

1. If you installed Secure Tunnel in IBM Cloud Pak for AIOps, log in to the IBM Cloud Pak for AIOps console. From the navigation menu (four horizontal bars), click **Administration** > **Secure Tunnel**.

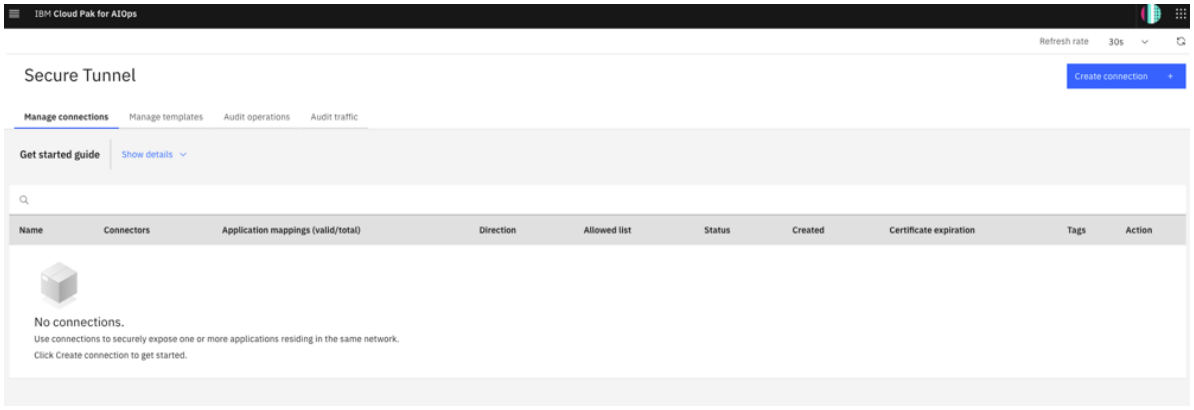

Figure. Secure Tunnel page

2. If Secure Tunnel is not installed in IBM Cloud Pak for AIOps, use the Red Hat OpenShift Container Platform route to access the stand-alone Secure Tunnel. To get the Secure Tunnel URL, enter the following command:

   ```
   oc get route -n <namespace> sre-tunnel-tunnel-ui -o jsonpath='{.spec.host}'
   ```

   Where **<namespace>** is the project (namespace) where Secure Tunnel is installed.

With the Secure Tunnel UI, you can create the following types of connections:

- ChatOps connection
- VMware connection
- Turbonomic connection
- OpenStack connection

- Custom connection

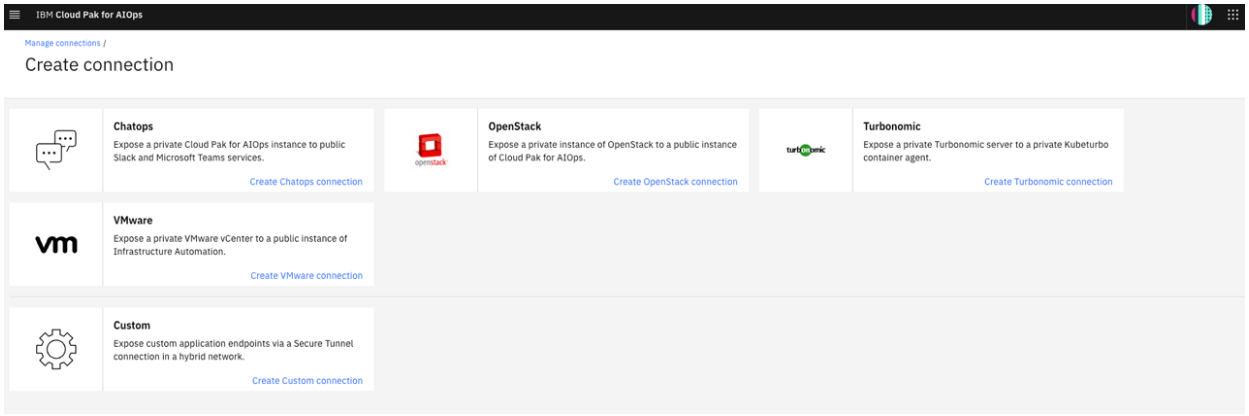

Figure. Secure Tunnel create connection page

Creating a Secure Tunnel

To create a Secure Tunnel connection, click **Create connection** on the Secure Tunnel UI and then follow the steps for the specific connection that you want to create.

ChatOps connection

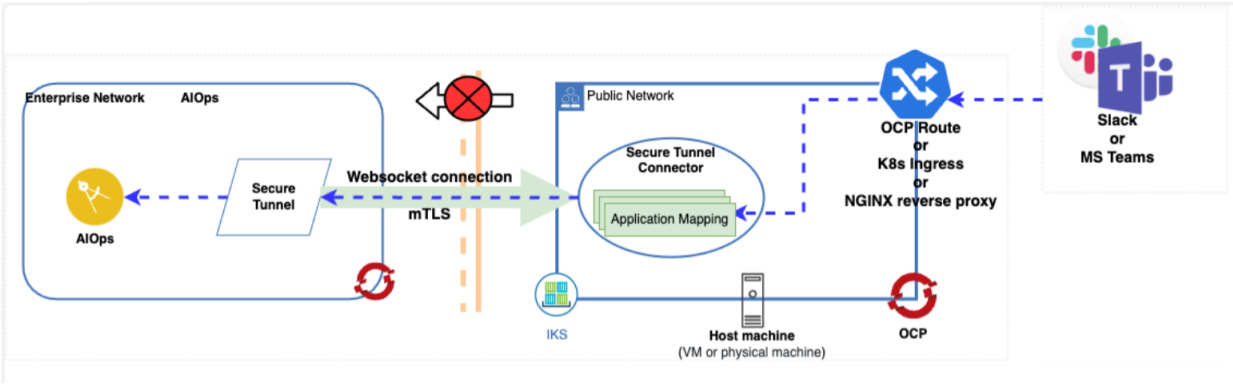

Figure. High-level design for VMware

To integrate IBM Cloud Pak for AIOps with a service like Slack or Microsoft Teams, the IBM Cloud Pak for AIOps instance needs to be accessible from the public network. If your IBM Cloud Pak for AIOps is not accessible from the public network, you can open the IBM Cloud Pak for AIOps instance to the public network by creating a Secure Tunnel. You can do it by exposing the IBM Cloud Pak for AIOps instance to either a cluster (Red Hat OpenShift Container Platform or IBM Kubernetes Service cluster) or a host machine (virtual machine or physical machine), which is accessible from the public network. Simplify the creation of a secure tunnel by using the ChatOps template from the Secure Tunnel Console on the **Manage connections** page. Take the following steps to create a ChatOps connection:

1. Click **Create ChatOps connection** and a panel with an introduction to the ChatOps template opens. Click **Get started**.

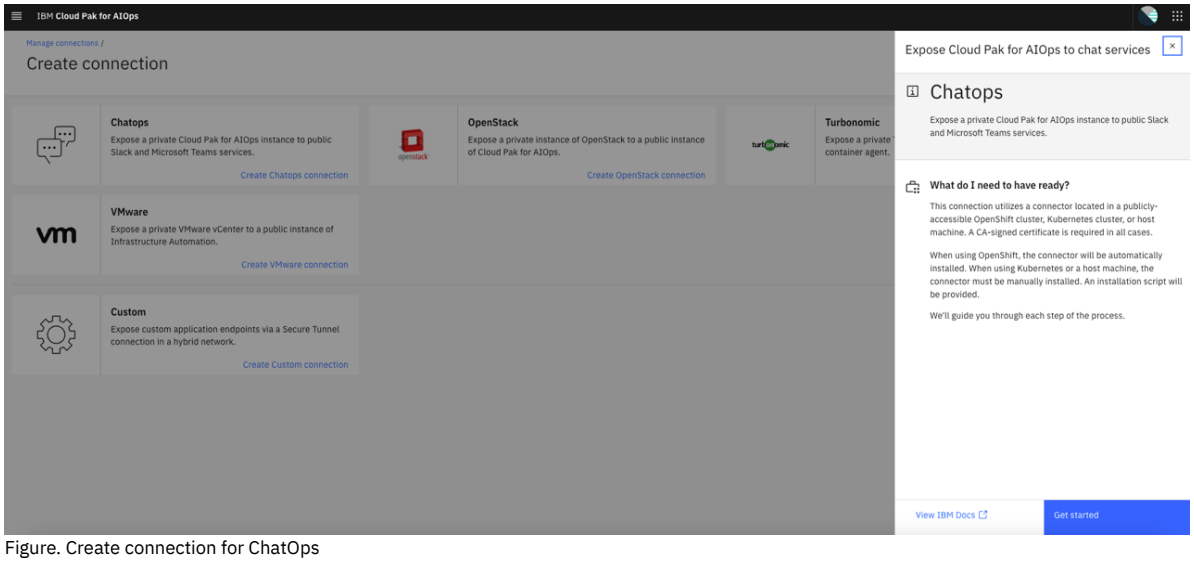

Figure. Create connection for ChatOps

2. In the *Name and Tags* section, provide a name and tag for this connection.

1. *Connection name*: required. The name of the connection. The name can include only lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
2. *New tag*: optional. The tag of the Connection.

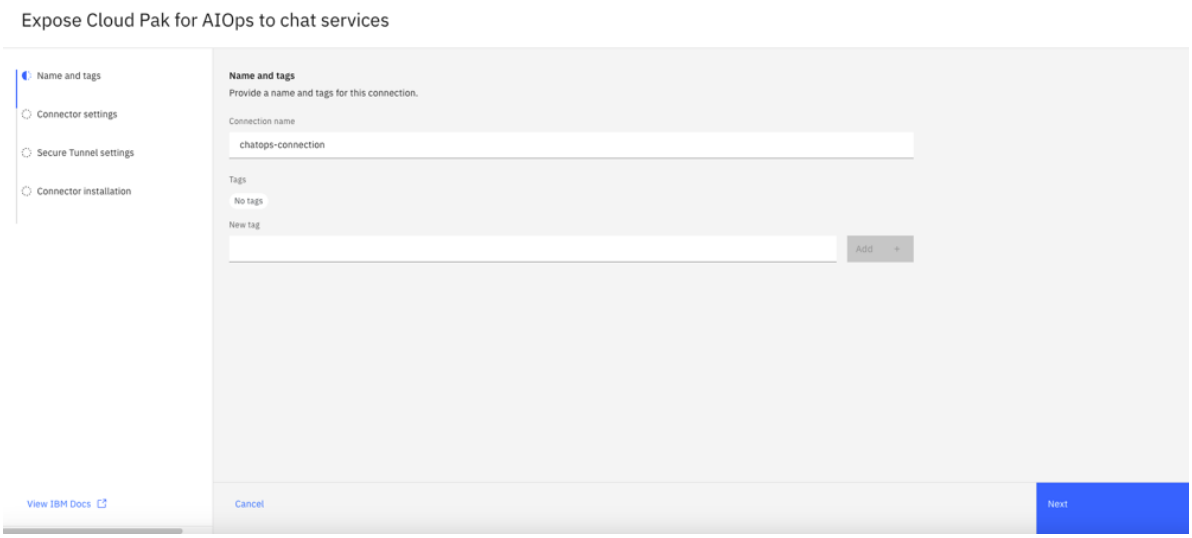

Figure. Name and tags for ChatOps

3. In the *Connector settings* section:

Specify the Connector location, such as *Cloud* or *Host machine*.

- If you choose to install the connector in the Red Hat OpenShift cluster, the connector can be installed automatically. Complete the following actions:
  - *Login command for target Red Hat OpenShift cluster*: required. Specify a publicly accessible cluster with a CA-signed domain certificate. Do not install the connector in the cluster that contains the Tunnel Connection worker.
  - *Target namespace to install the connector*: required. The project (namespace) where you want to install the connector.
  - *Connector replicas*: configure the tunnel connector replicas to set High Availability
- If you choose to install the connector on a Red Hat OpenShift Container Platform cluster manually, you can use the Custom method
- If you choose to install the connector in a Kubernetes cluster, complete the following actions:
  - *Cloud domain*: Run the command to get IBM Kubernetes Service cluster domain name:

```
ibmcloud ks cluster get --cluster <Cluster ID> --output json | jq '.ingress.hostname'
```

  - *Port*: required. The port of the Kubernetes cluster.
  - *Connector replicas*: you will config the tunnel connector replicas to set High Availability.

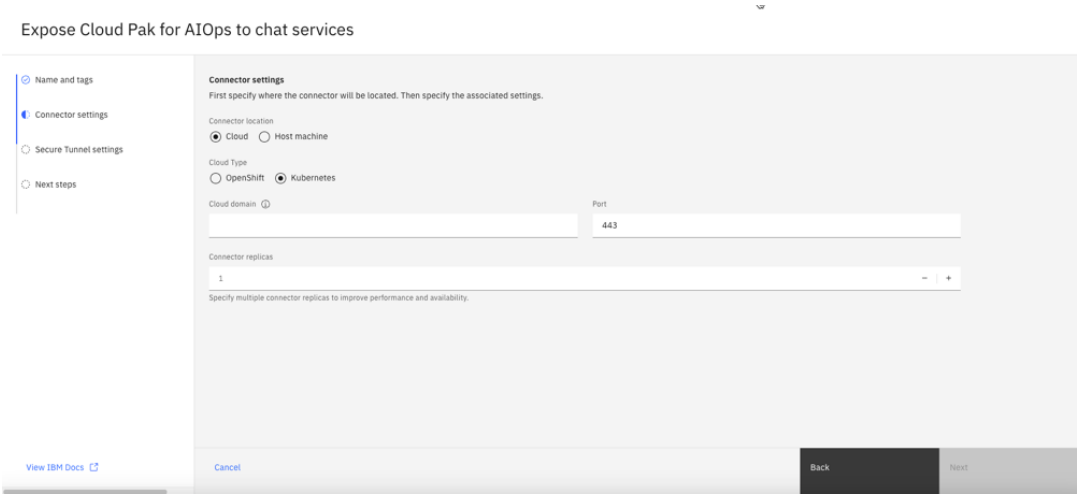

Figure. Connector settings for Kubernetes

- If you choose to install the connector in the *Host machine*, complete the following actions:
  - *Host machine addresses*: required. Includes the host machine external address, Port, host machine default address. When a host machine includes multiple addresses, a default IP address is required. If you want to use one host machine to expose more than one IBM Cloud Pak for AIOps, you need to set a different port for other ChatOps connections.
    - *Expose mapping port*: required. Default is **12443**. You can change this port to allow several IBM Cloud Pak for AIOps instances to have different exposed ports. Then, you can use one host machine to create more than one ChatOps connection.

- *DNS and load balancing*: required. First, enter the DNS name of a suitable host machine. Next, select the same machine to host a reverse proxy / load balancer (bundled with the connector). Finally, specify the corresponding certificate and private key.

  Note: If you have an IBM Cloud account, see Getting started with IBM Cloud Internet Services to apply for a **DNS name**, and see Preparing to order public certificates to apply for a CA-signed certificate. Extract the CA-signed certificate file, **`hostname.pem`**, for the certificate and **`hostname.key`** for the private key. If an intermediate file is in your CA-signed certificate file – such as hostname-intermediate.pem – concatenate this file with a cert file, such as hostname.pem, by running the following command:

  ```
  cat hostname-intermediate.pem >> hostname.pem
  ```

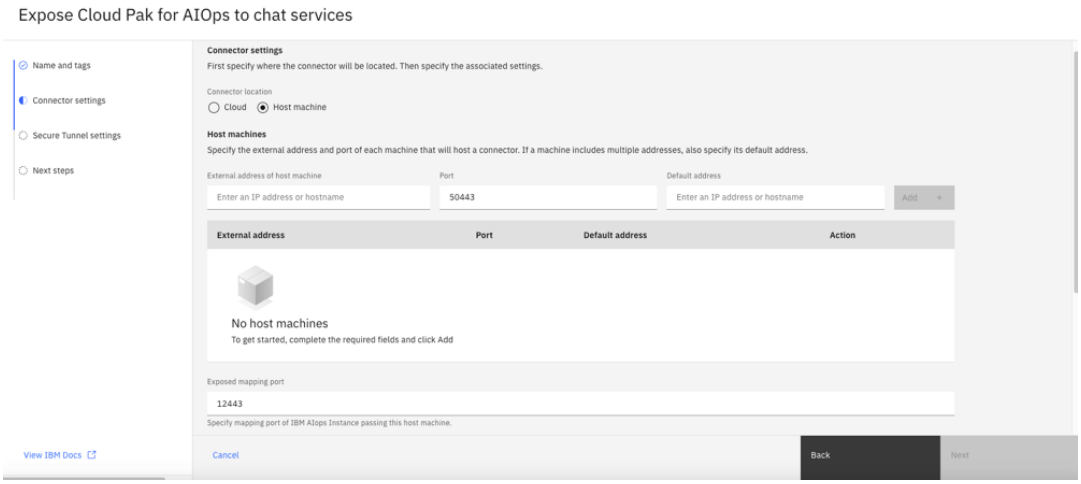

Figure. Connector settings for Host machine

4. In the *Secure Tunnel settings*, configure the tunnel worker replicas to set High Availability.

5. *HTTPS proxy*: optional. Specify a forward proxy to enable the Secure Tunnel to reach the connector in the other network, such as username:password@hostname:port.

   Note: It is necessary to enter the HTTPS proxy information when Secure Tunnel is in an air-gapped environment. If your Secure Tunnel is in an air-gapped environment without internet connectivity, you need to prepare a host machine (virtual machine or physical machine). Ensure that the host machine can be accessed from the IBM Cloud Pak for AIOps cluster, and also that it can connect to the internet. Then, install an HTTPS proxy server in the host machine, and set the HTTPS proxy server in the HTTPS proxy field.

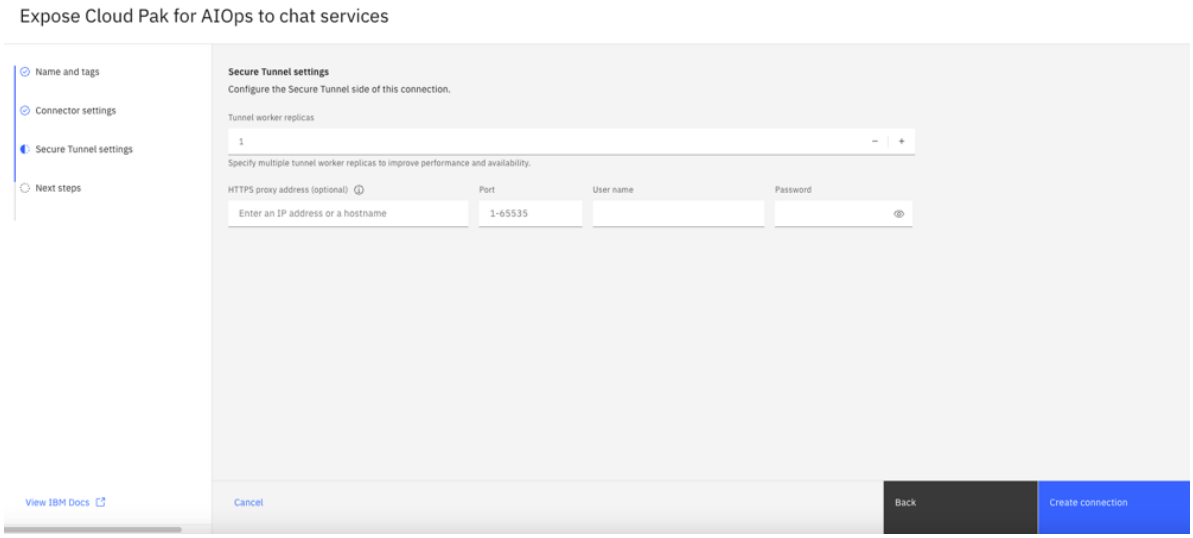

Figure. Secure Tunnel settings for ChatOps

If you install a connector in Red Hat OpenShift Container Platform, and the Secure Tunnel in an air-gapped environment and you configured the HTTPS proxy for it, choose **Kubernetes** for the **Cloud Type** in the above step. Then, to get the domain for the **Cloud domain** field, run

```
HOSTNAME=$(oc get route -n openshift-console console -o=jsonpath={.spec.host}) && HOSTNAME=${HOSTNAME#console-openshift-console.} && echo $HOSTNAME
```

For example, squid is a simple HTTPS proxy server. See the following example of using squid to set up an HTTPS proxy server (Do not use this example in your production environment). For a production environment, contact your network administrator to help you configure the HTTPS proxy.

Save the following configurations in a file **`squid.conf`**:

```
acl all src 0.0.0.0/0.0.0.0
acl SSL_ports port 443
acl CONNECT method CONNECT

http_access deny CONNECT !SSL_ports
```

```
http_access allow all

# Squid normally listens to port 3128
http_port 3128

# Uncomment and adjust the following to add a disk cache directory.
cache_dir ufs /var/spool/squid 100 16 256
# Leave coredumps in the first cache dir
coredump_dir /var/spool/squid
#
# Add any of your own refresh_pattern entries above these.
#
refresh_pattern ^ftp:         1440    20%    10080
refresh_pattern ^gopher:    1440    0%    1440
refresh_pattern -i (/cgi-bin/|\?) 0    0%    0
refresh_pattern (Release|Packages(.gz)*)$      0       20%     2880
# example lin deb packages
#refresh_pattern (\.deb|\.udeb)$   129600 100% 129600
refresh_pattern .         0    20%    4320
```

Start the squid server by running the following command:

```
podman run --name squid -d -p 3128:3128 -v `pwd`/squid.conf:/etc/squid/squid.conf datadog/squid
```

Set the `<host machine IP>:3128` in the **HTTPS proxy** field.

6. Click **Create connection** to create a ChatOps connection.

   - If you choose to install the connector on a Red Hat OpenShift cluster, the connector is automatically installed. You can see the installation status in the connector installation section. When the installation is finished, you can get the application mapping URLs for Slack and Microsoft Teams connections.
   - If you choose to install the connector on Kubernetes or a host machine, the connector must be manually installed. You can get the installation script in the *Next steps* section. Install the connector following this installation guide. When the connector is installed, you can use the appropriate application mapping address to integrate with Slack or Microsoft Teams.

ChatOps connection (Microsoft Azure as host machine)

To set up a ChatOps connection with Microsoft Azure as the host machine, you need to install IBM Cloud Pak for AIOps in *network-A* (private cloud) and set up ChatOps in *network-B* (Slack or Microsoft Teams in public cloud). This process involves configuring ChatOps and a Secure Tunnel out of *network-A* to communicate with ChatOps in the public cloud, *network-B*.

1. Install IBM Cloud Pak for AIOps.
2. User deploys a VM to Azure, gives it a public internet-facing endpoint. **Note:** This must have a signed trusted certificate that ChatOps accepts as trusted (that is not self-signed).
3. On Azure, open the `50443` port on the VM that uses an NSG (Network Security Group).
4. Give the VM a public DNS name.
5. Check whether it is a private IP on the Azure UI. For example, the private IP in this case is `172.18.0.4`:

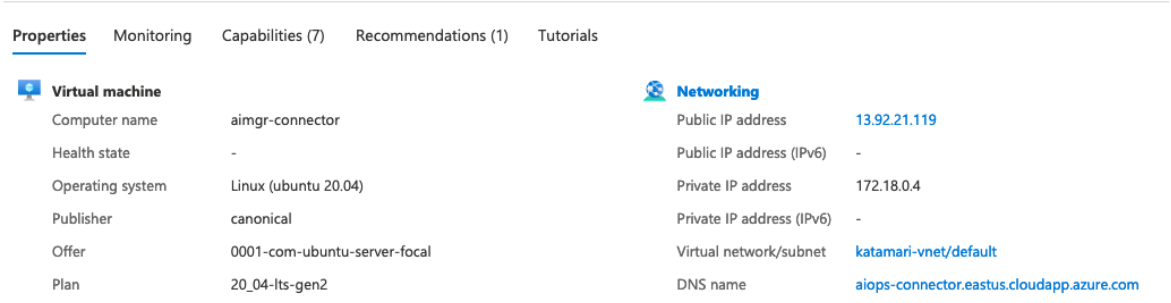

Figure. Azure UI

6. Get the signed trusted certs, including the root and any intermediate CAs.
7. To configure the tunnel connector on the Secure Tunnel UI, enter the following details:

   1. Select *Connector Location* as `Cloud`.
   2. Enter the *External address of host machines*. This is the IP address/addresses of host machines. For example, aiops-cocnnector.eastus.cloudapp.azure.com.
   3. Enter *Port*. This is the port number of the host.
   4. Enter *Exposed Mapping Port* . The default is `12443`. You can change this port to allow several IBM Cloud Pak for AIOps instances to have different exposed ports.
   5. For *DNS and load balancing*, enter the DNS name of a suitable host machine. Next, select the same machine to host a reverse proxy / load balancer (bundled with the connector).

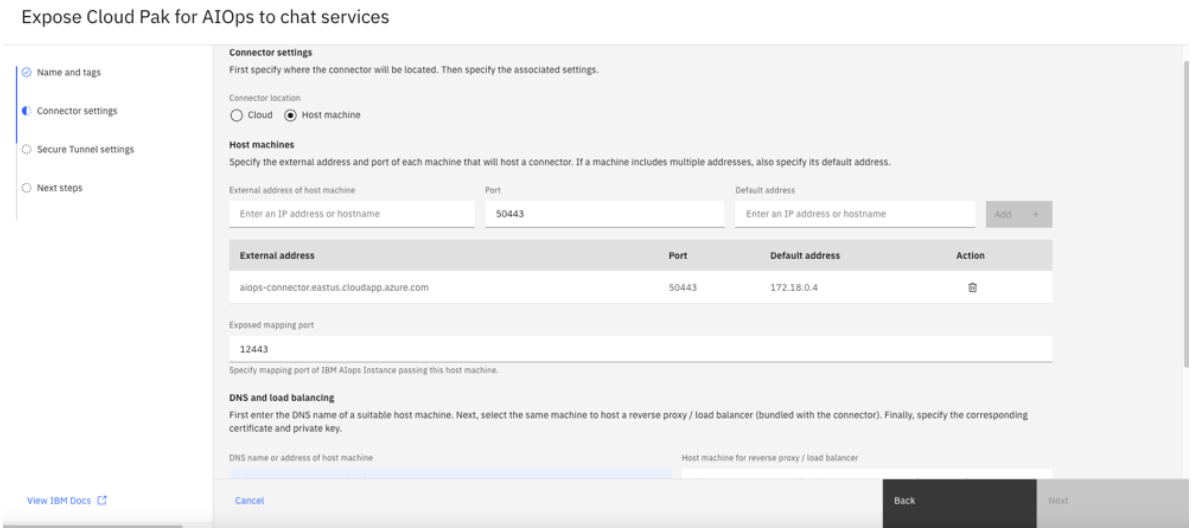

Figure. Connector settings for ChatOps

8. Note where the private IP is entered and note the values for DNS. You need to select the host machine in the dropdown menu.
9. Enter your cert and keys in the connector UI.

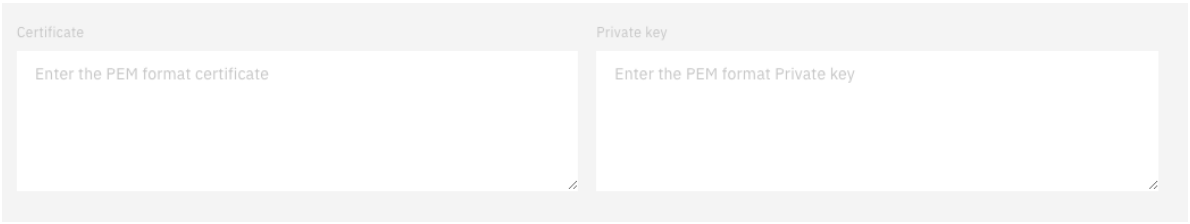

Figure. Enter certifaction keys

10. You then get a **`tar.gz`**. Download this file and transfer it to Azure VM.
11. On the Azure VM, where you unpack the download, ensure that nothing is connected to the **`443`** port (like an Apache server) and run the secure tunnel installer as root, as it needs that privilege to bind to the **`443`** port.
12. You then get a successful installation and see a *Ready* status back on the Secure Tunnel UI.

    Script output

```
Install Tunnel Connector successfully
{"ok":true}
{"ok":true}

Start Tunnel Connector successfully

{"description":""}
{"description":""}
A
Tunnel Connector is ready to use.
```

    IBM Cloud Pak for AIOps UI

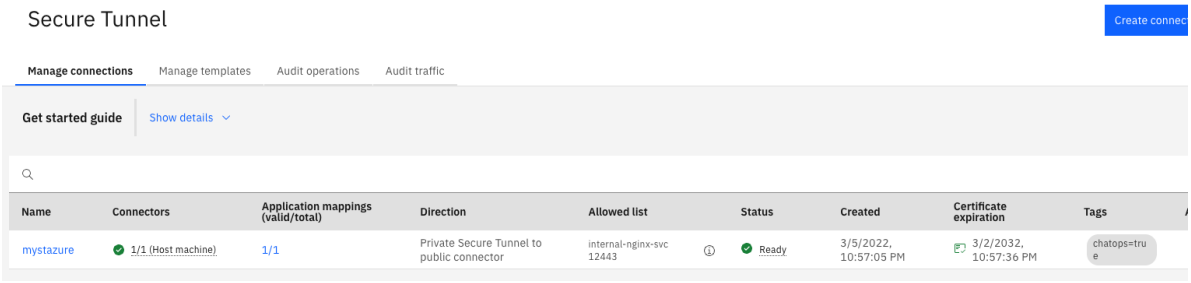

Figure. Additional Secure Tunnel UI

13. Click the application mappings entry, which shows you the URLs to use in your Slack or Microsoft Teams. You can renew the certificate and private key by editing the application mapping.

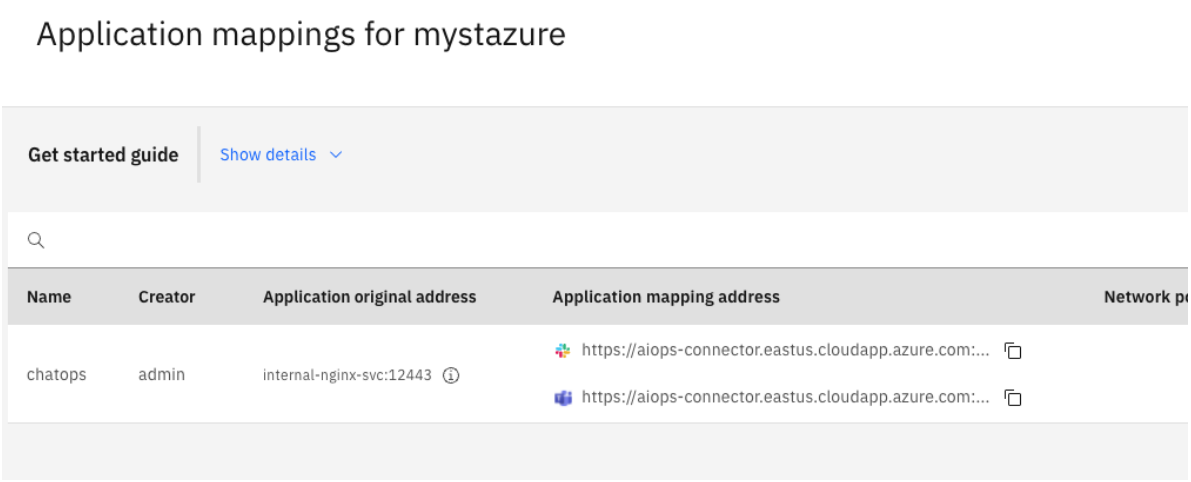

Figure. Application mappings

14. In the Microsoft Teams bot, enter the URL in the *Messaging endpoint* field.

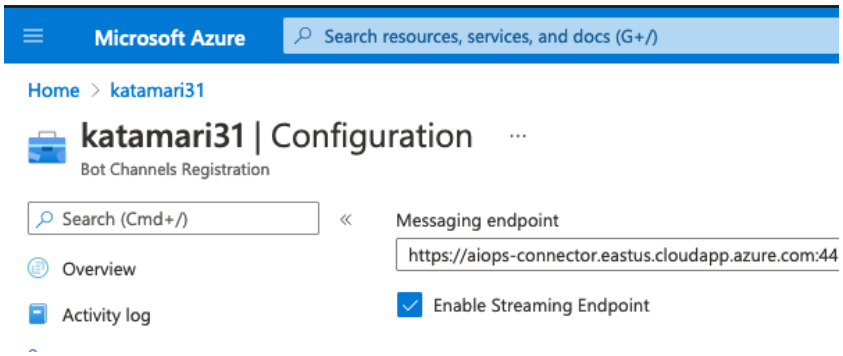

Figure. Azure team

VMware connection

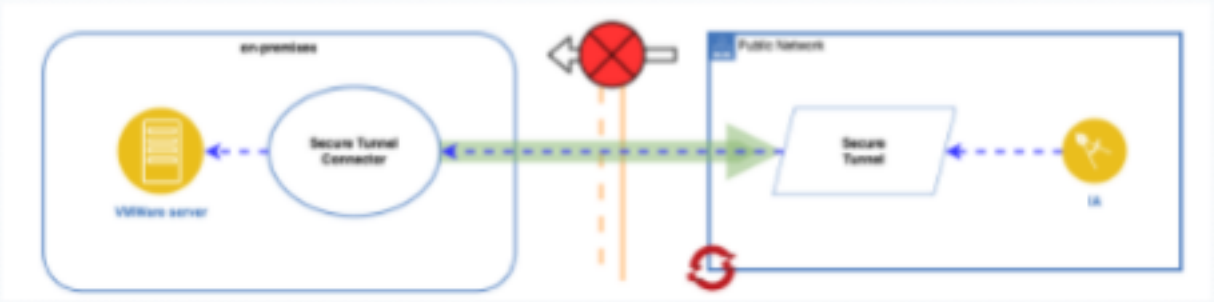

Figure. High-level design for VMware

Follow the installation instructions to install Secure Tunnel.

You can access services in a private VMware® vCenter from a public cloud **Infrastructure automation**. In this case, install a Secure Tunnel in the Infrastructure automation cluster, with IBM Cloud Pak for AIOps or a stand-alone version. Then, take the following steps to configure the VMware tunnel connection:

Note: VMware template supports the VMware scenario specifically. Other scenarios can be created by using a Custom template.

Simplifying the creation of a Secure Tunnel by using VMware template in IBM Cloud Pak for AIOps:

1. Click the **VMware** tile. The VMware side panel opens and provides an introductory explanation to the VMware template. Click **Get started**.
2. In the *Name and Tags* section, provide a name and tag for this connection:
    1. Connection name: required. The name of the connection. The name can include only lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
    2. New tag: optional. The tag of the Connection.
3. In the *Connector settings* section, install the tunnel connector to *Cloud* or *Host machine* by selecting the connector location and fill the section with appropriate details.

    If you choose to install the connector in the *Host machine*, complete the following actions:

    - *Host machine addresses*: optional. Includes the host machine external address, Port, host machine default address. When a host machine includes multiple addresses, a default IP address is required. If you want to use one host machine to expose more than one IBM Cloud Pak for AIOps, you need to set a different port for other ChatOps connections.

- *DNS and load balancing*: optional. First, enter the DNS name of a suitable host machine. Next, select the same machine to host a reverse proxy / load balancer (bundled with the connector).

If you choose to install the connector in the *Cloud*, complete the following actions:

- *Connector replicas*: configure the tunnel connector replicas to high availability.

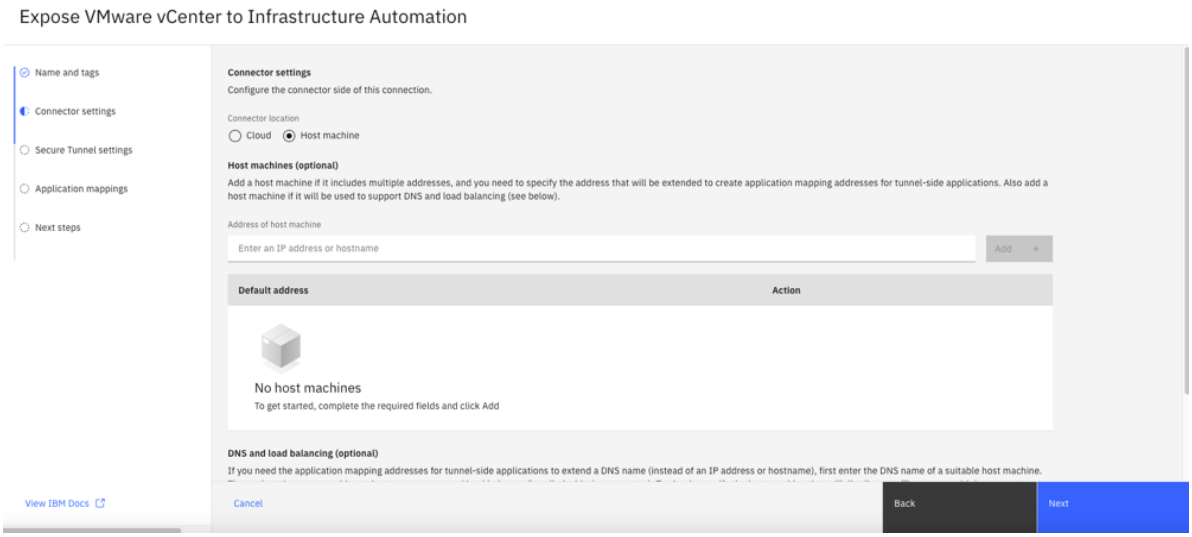

Figure. Connector settings for VMware

4. In the *Secure Tunnel setting*, configure the tunnel worker replicas to set High Availability.
5. *HTTPS proxy*: optional. Specify a forward proxy to enable the Secure Tunnel to reach the connector in the other network, such as username:password@hostname:port.

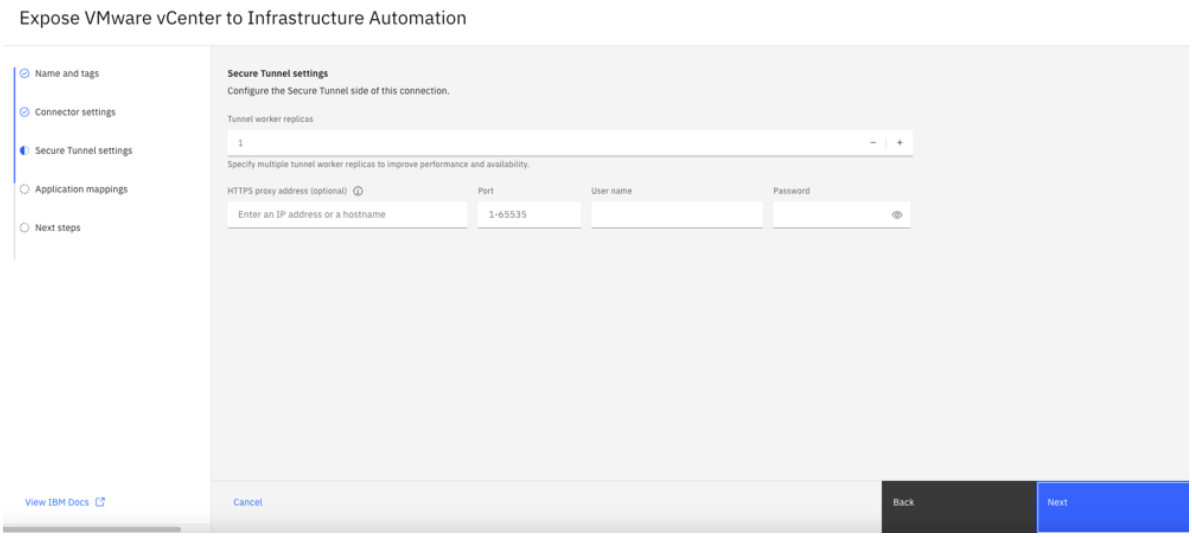

Figure. Tunnel settings for VMware

Note: It is necessary to enter the HTTPS proxy information when Secure Tunnel is in an air-gapped environment. If your Secure Tunnel is in an air-gapped environment without internet connectivity, you need to prepare a host machine (virtual machine or physical machine). Ensure that the host machine can be accessed from the IBM Cloud Pak for AIOps cluster, and can also connect to the internet. Then, install an HTTPS proxy server in the host machine, and set the HTTPS proxy server in the HTTPS proxy field.

If you install the connector in OCP, and Secure Tunnel in an air-gapped environment, you need use the Custom method to create a ChatOps connection

For example, squid is a simple HTTPS proxy server. See the following example of using squid to set up an HTTPS proxy server. (It is just an example. Don't use it in your production environment.) For the production environment, contact your network administrator to help you configure the HTTPS proxy.

1. Save the following configurations in a file squid.conf.

```
acl all src 0.0.0.0/0.0.0.0
acl SSL_ports port 443
acl CONNECT method CONNECT

http_access deny CONNECT !SSL_ports

http_access allow all

# Squid normally listens to port 3128
```

```
http_port 3128

# Uncomment and adjust the following to add a disk cache directory.
cache_dir ufs /var/spool/squid 100 16 256
# Leave coredumps in the first cache dir
coredump_dir /var/spool/squid
#
# Add any of your own refresh_pattern entries above these.
#
refresh_pattern ^ftp:         1440    20%    10080
refresh_pattern ^gopher:    1440    0%    1440
refresh_pattern -i (/cgi-bin/|\?) 0    0%    0
refresh_pattern (Release|Packages(.gz)*)$      0       20%     2880
# example lin deb packages
#refresh_pattern (\.deb|\.udeb)$   129600 100% 129600
refresh_pattern .         0    20%    4320
```

2. Start the squid server by running the following command:

```
podman run --name squid -d -p 3128:3128 -v `pwd`/squid.conf:/etc/squid/squid.conf datadog/squid
```

3. Set the `< host machine IP >:3128` in the *HTTPS proxy* field.

6. In the *Application mappings* section, edit the VMware addresses to match your environment. If it is the same as the address in the template, you don't need to change anything.

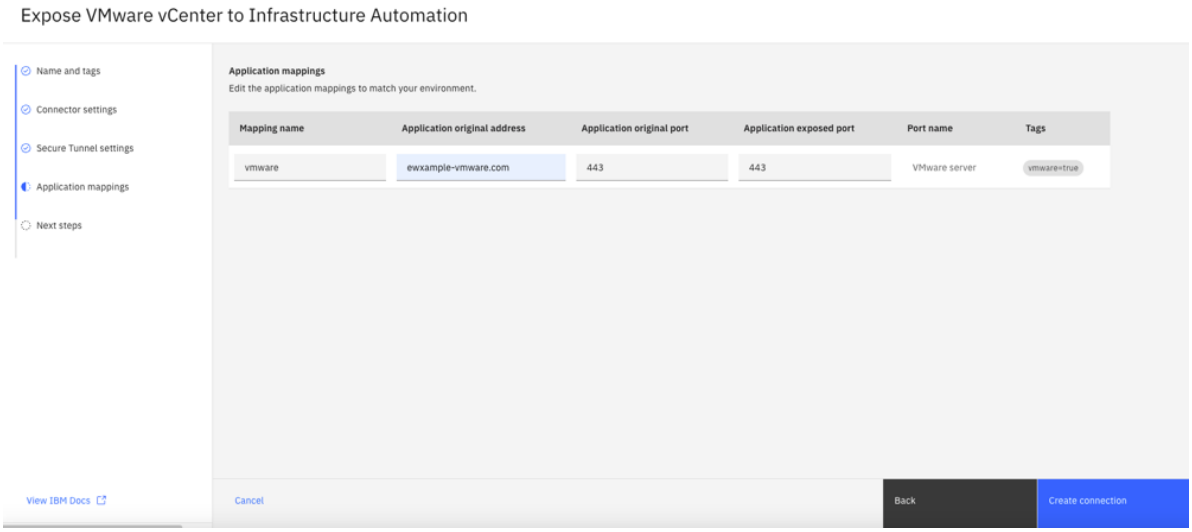

Figure. Application mappings for VMware

7. Click **Create connection** to create a VMware connection. You can get the installation script in the *Next steps* section. Install the Connector following the guide. When the connector is installed, the application mapping address is accessible. You can use this address as the VMware vCenter service address to configure the VMware connection from the Infrastructure Automation UI.

Turbonomic connection

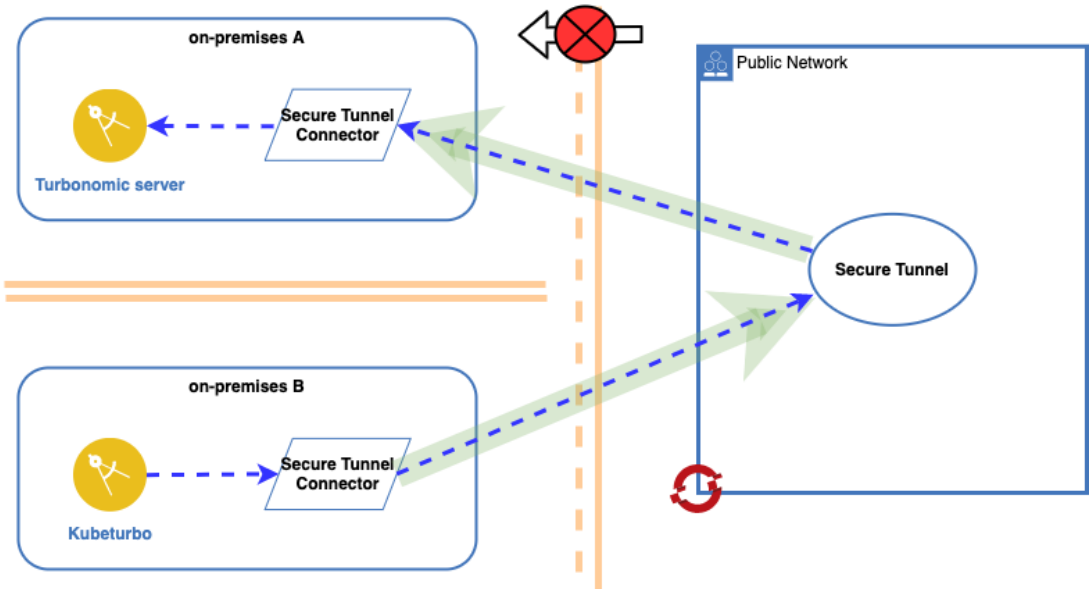

Figure. High-level design for Turbonomic

The Turbonomic server is in one private network cluster and you want to integrate it with a kubeturbo probe in another private network.

In this case, install a stand-alone Secure Tunnel on a public Cloud. Then, create one tunnel connection to export the **Turbonomic** server endpoint to the public cloud cluster. Next, create another tunnel connection to export the exposed **Turbonomic** server endpoint (a Kubernetes service in the public cloud cluster) to the **kubeturbo** private network cluster. The **kubeturbo** can now access the **Turbonomic** server through the Secure Tunnel.

Simplifying the creation of a secure tunnel by using the Turbonomic template:

1. Click the **Turbonomic** tile to open the Turbonomic side panel. Next, click **Get started** to create a connection. The first connection exposes Turbonomic to the Secure Tunnel server.
2. In the *Name and Tags* section, provide a name and tags for this connection:
   - *Connection name*: required. The name of the connection. The name can include only lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
   - *New tag*: optional. The tag of the Connection.
3. In the *Performance and availability* section:
   - *Connector replicas*: configure the tunnel connector replicas to High Availability
   - *Tunnel worker replicas*: configure the tunnel connector replicas to High Availability

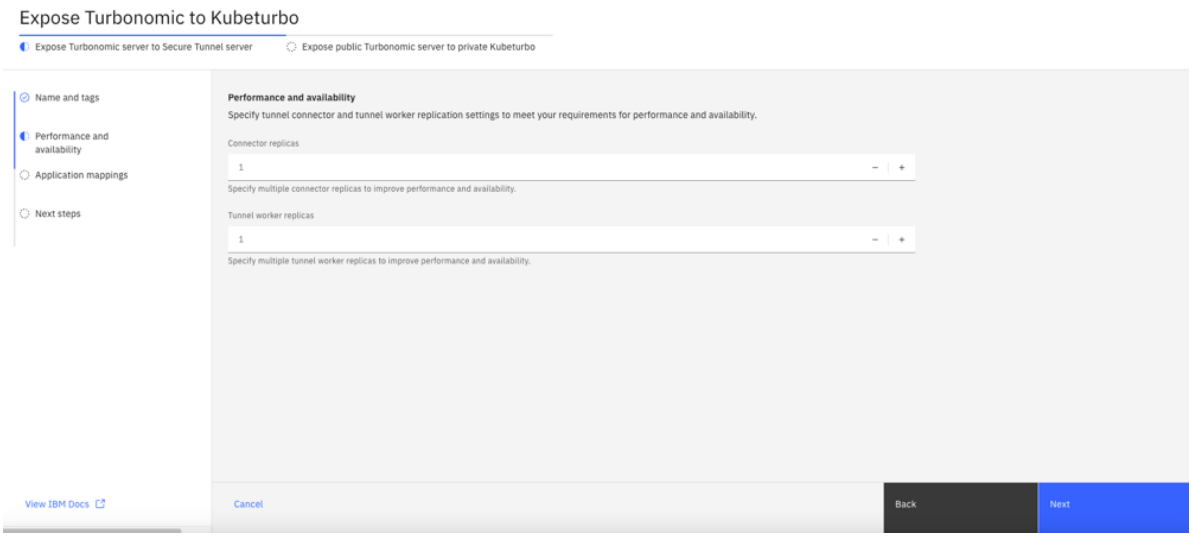

Figure. Performance and availability for Turbonomic

4. In the *Application mappings* section, edit the Turbonomic server addresses to match your environment.(**In particular, check the namespace part of the Turbonomic Kubernetes service address, and check whether it matches the Turbonomic Kubernetes service address**). If it is the same as the address in the template, you don't need to change anything.

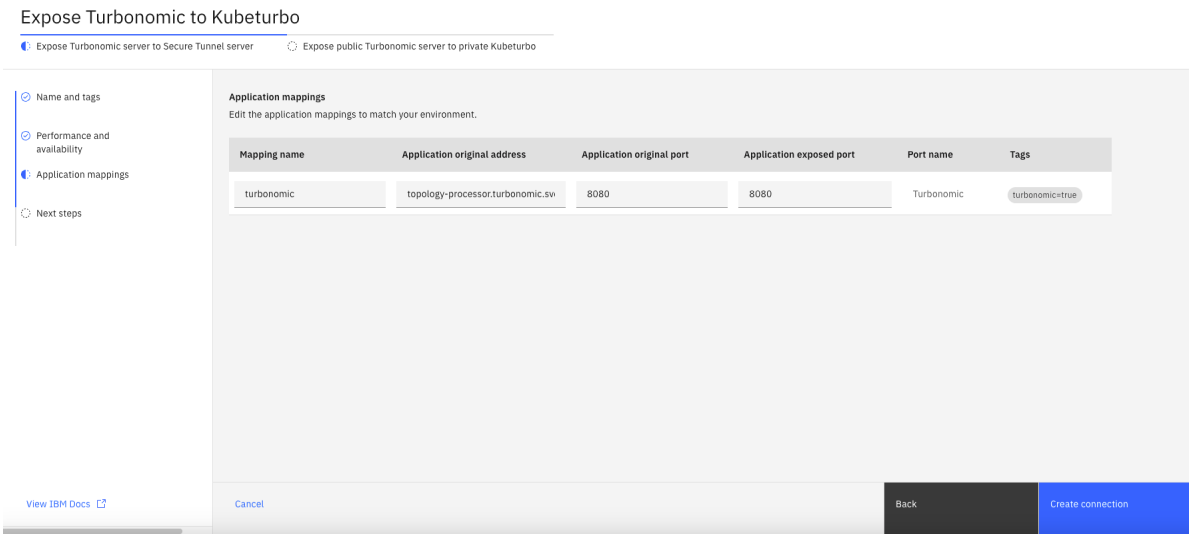

Figure. Application mappings for Turbonomic

5. Click **Create connection** to create a Turbonomic connection to expose the Turbonomic server to the public cloud cluster (as a Kubernetes network service), then you get the installation script in the *Next steps* section. You can install the connector by following this guide or install it later in the *Manage connections* page, by clicking **Action** > **installation connector**.

6. Click **Next**. Install the second connection. This step is the same as the first. The difference is that you cannot change the application address in the **Application mappings** section. Now create a tunnel connection to export the exposed **Turbonomic** server from the public cluster (a Kubernetes network service) to the **kubeturbo** private network cluster. Then, click **Create connection** to create a Turbonomic connection. You can get the installation script in the **Next steps** section, and install the connector.

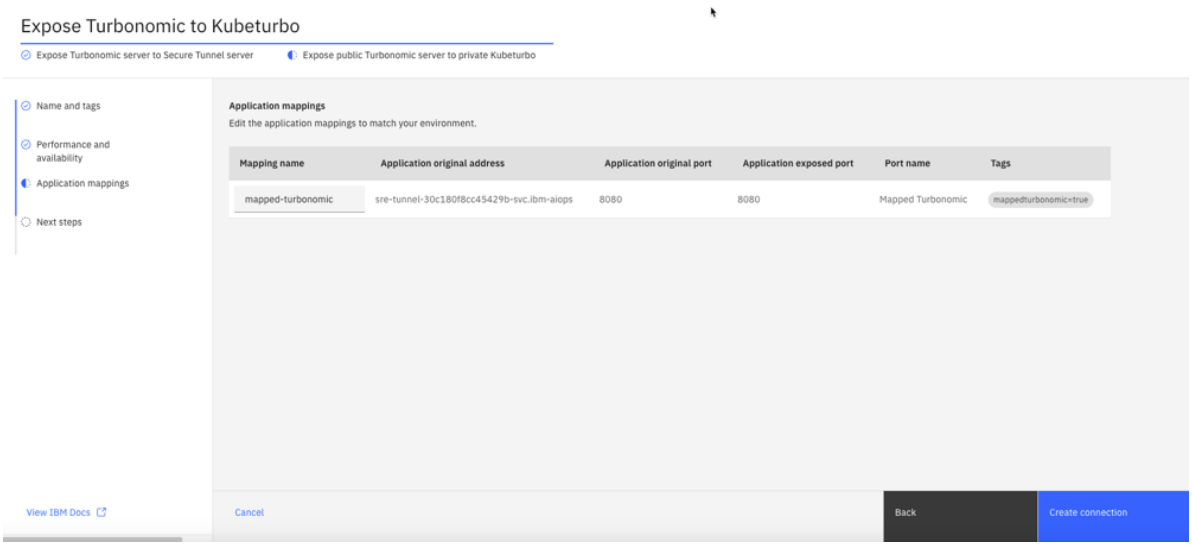

Figure. Application mappings for Turbonomic for the second connection

7. Finally, select the **<the name that you provided in the Name and Tags>-kubeturbo** tunnel connection and obtain the application mapping address. Then, you can use this application mapping address as the Turbonomic server address in the **kubeturbo**. The address is similar to this: **http://sre-tunnel-9a4f8fbb26374fa7.tunnel-connector-turbo:8080**.

8. Install the **kubeturbo**. Create a Project(namespace), like **kubeturbo**, to install the **kubeturbo** operator and instance from the Red Hat OpenShift console **OperatorHub**. Enter **kubeturbo** into the **All Items** field. Click the **Kubeturbo Operator** panel to install the **kubeturbo**. Navigate to **Installed Operators** > **Kubeturbo Operator**, click **Create instance** from the **Kubeturbo operator** panel. Change to the **YAML View** and edit the YAML like this:

```
spec:
  replicaCount: 1
  restAPIConfig:
    opsManagerPassword: <password of the Turbonomic server>
    opsManagerUserName: <username of the Turbonomic server>
  serverMeta:
    turboServer: '<the turbo server application mapping address, should be like: http://sre-tunnel-
9a4f8fbb26374fa7.tunnel-connector-turbo:8080>'
    version: '8'
  targetConfig:
    targetName: <give a name like: tunneltest>
```

Note: Check that the connectors have successfully installed for the two connections. One is in the private Turbonomic server cluster, the other is in the private kubeturbo agent container.

OpenStack connection

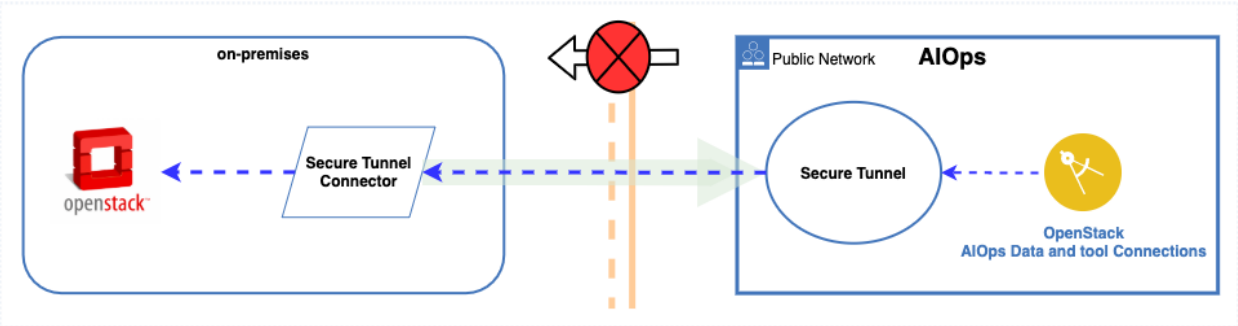

Figure. High-level design for Openstack

Scenario: The OpenStack server is in a private network cluster and IBM Cloud Pak for AIOps is in a public cluster. To integrate with the private OpenStack server, you can use a Secure Tunnel to create an OpenStack connection. The OpenStack template that is described in the following section supports this type of connection. You can create other templates through a custom connection. For more information, see Custom connection.

Simplifying the creation of a Secure Tunnel by using an OpenStack template:

From the **Secure Tunnel Console** on the **Manage connections** tab page, click *Create connection*. Then, take the following steps to create an OpenStack connection:

1. Click the **OpenStack** tile. The OpenStack introductory side panel opens. Click **Get started**.

2. In the *Name and Tags* section, provide a name and tags for this connection:

- *Connection name*: required. The name of the connection. The name can include lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
- *New tag*: optional. A tag for the connection.

3. In the *Connector settings* section, configure the tunnel connector replicas to set High Availability and choose to install the tunnel connector to *Cloud* or *Host machine* by selecting the *Connector location* section.
4. In the *Secure Tunnel setting*, configure the tunnel worker replicas to set High Availability.
5. In the *HTTPS proxy*, optionally specify a forward proxy to enable the Secure Tunnel to reach the connector in the other network, such as *username:password@hostname:port*.

   Note: It is necessary to enter the HTTPS proxy information when Secure Tunnel is in an air-gapped environment. If your Secure Tunnel is in an air-gapped environment without internet connectivity, you need to prepare a host machine (virtual machine or physical machine). Ensure that the host machine can be accessed from the IBM Cloud Pak for AIOps cluster, and can also connect to the internet. Then, install an HTTPS proxy server in the host machine and set the HTTPS proxy server in the HTTPS proxy field.

   For example, squid is a simple HTTPS proxy server. See the following example of using squid to set up a HTTPS proxy server. Do not use this example in your production environment. For the production environment, contact your network administrator to help you configure the HTTPS proxy.

   1. Save the following configurations in a file squid.conf.

```text {: codeblock}
acl all src 0.0.0.0/0.0.0.0
acl SSL_ports port 443
acl CONNECT method CONNECT

http_access deny CONNECT !SSL_ports

http_access allow all

# Squid normally listens to port 3128
http_port 3128

# Uncomment and adjust the following to add a disk cache directory.
cache_dir ufs /var/spool/squid 100 16 256
# Leave coredumps in the first cache dir
coredump_dir /var/spool/squid
#
# Add any of your own refresh_pattern entries above these.
#
refresh_pattern ^ftp:         1440    20%     10080
refresh_pattern ^gopher:      1440    0%      1440
refresh_pattern -i (/cgi-bin/|\?) 0     0%      0
refresh_pattern (Release|Packages(.gz)*)$       0       20%     2880
# example lin deb packages
#refresh_pattern (\.deb|\.udeb)$   129600 100% 129600
refresh_pattern .         0     20%     4320
```

   2. Start the squid server by running the following command:

```sh {: codeblock}
podman run --name squid -d -p 3128:3128 -v `pwd`/squid.conf:/etc/squid/squid.conf datadog/squid
```

   3. Set the :3128 in the HTTPS proxy field.
6. In the *Application mappings* section, edit the OpenStack addresses to match your environment, and enable *Origin application uses HTTPS*.

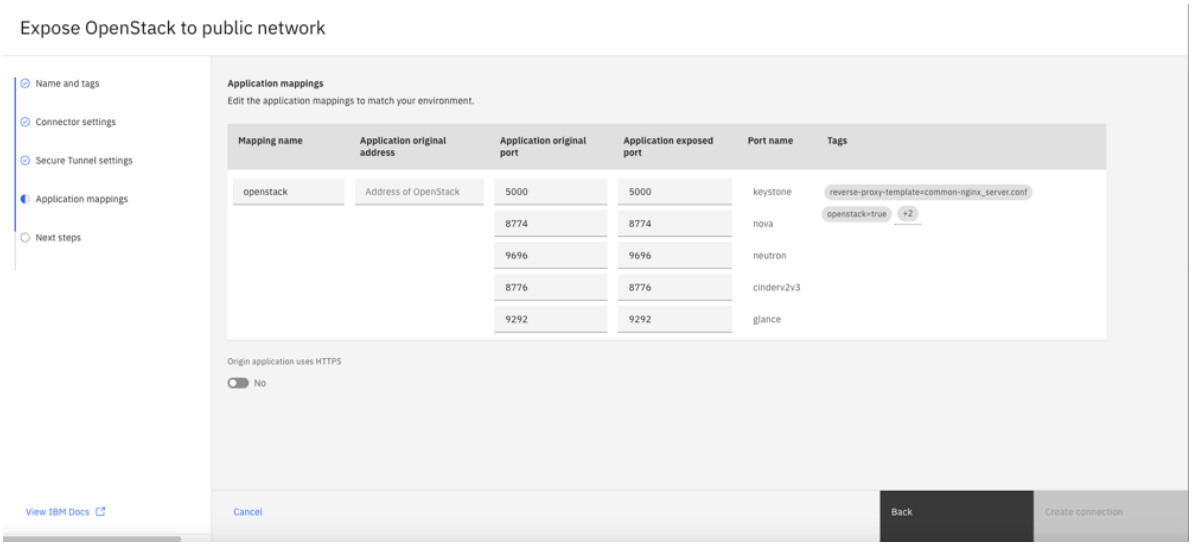

Figure. Application mappings for Openstack

7. Click **Create connection** to create an OpenStack connection. You can get the installation script in the **Next steps** section. Follow the installing connector steps. After installing the connector, the application mapping address is accessible. Use this address as the VMware vCenter service address to configure the VMware connection from the Infrastructure Automation UI.

Custom connection

Secure Tunnel can accommodate specific requirements with a Custom connection. For instance, you can use this type of connection for ChatOps to help you understand how to customize your own connection.

The installation connector in Red Hat OpenShift is automatically supported when you use the ChatOps template. If you do not prefer this approach, you can install the connector in Red Hat OpenShift manually with the Custom method.

Use case summary: IBM Cloud Pak for AIOps is installed. Slack (for ChatOps) is in a public network. To access IBM Cloud Pak for AIOps, expose the IBM Cloud Pak for AIOps instance to the public cluster through a connector that is installed in Red Hat OpenShift.

1. Create a **connection** to create a bridge configuration for the network where **Secure Tunnel** is installed and the network that has the connector.
    1. Click **Custom** tile. This opens the Custom side panel. Then, click **Get started**.
    2. In the *Name and Tags* section, Provide a name and tags for this connection:
        - Connection name: required. The name of the connection. The name can include lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
        - New tag: optional. The tag of the Connection. Add the tag **`chatops=true`** in our example.
    3. In *Direction*, specify whether the relationship is one of below:
        - *connector in private network initializes connection to Secure Tunnel in public network*
        - *Secure Tunnel in private network initializes connection to connector in public network*.

       Because Secure Tunnel is in the IBM Cloud Pak for AIOps cluster, choose option **Secure Tunnel in private network initializes connection to connector in public network**.

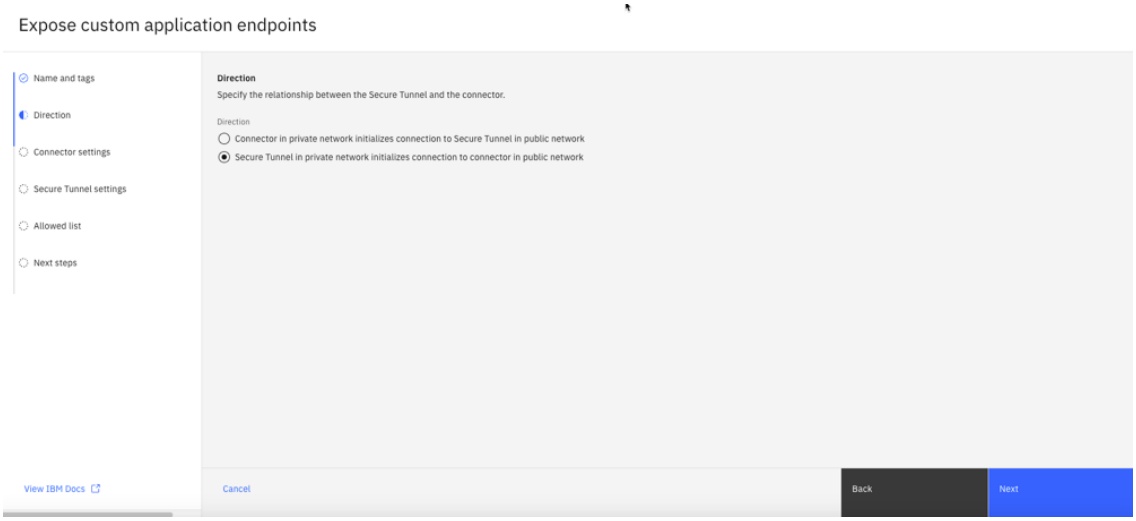

Figure. Direction for custom connection

    4. In the **Connector settings** section:
        1. *Connector location*: required. Select whether installation connector is in the *Cloud* or in a *Host machine*. Because the connector is installed on Red Hat OpenShift, choose **Cloud**.
        2. *Connector replicas*: Configure the tunnel connector replicas to set High Availability, 1 - 16, as you need.
        3. *Cloud domain*: If you install the connector in the Cloud direction, the Secure Tunnel in the private network initializes the connection to a connector in a public network. You need to input the cloud domain of the cluster where you installed the connection. Run this command to get the Red Hat OpenShift cluster domain name:

           ```
           oc get route -n openshift-console console -o jsonpath={.spec.host} | sed -e 's/[^\.]*\.//
           ```

           Run this command to get the IBM Kubernetes Service cluster domain name:

           ```
           ibmcloud ks cluster get --cluster <Cluster ID> --output json | jq '.ingress.hostname'`
           ```

        4. Host Machine: if you install the connector in a VM or Physical machine, you need:
            1. Host machine addresses
                1. If your Connection direction is *Secure Tunnel in private network initializes connection to connector in public network*, it must include the *External address of host machine* and *Port* and *Default address of host machine* .(Optionally, specify a default IP address when a host machine includes multiple addresses).
                2. If your connection direction is *Connector in private network initializes connection to Secure Tunnel in public network* it must include *Default address of host machine* (optionally, specify a default IP address when a host machine includes multiple addresses.)
                3. *Common DNS name for all inbound traffic (optional)*: required, in this case. Specify a DNS name for all inbound (connector to tunnel) traffic. When multiple host machines are present, you can enter a DNS name or the external IP address or hostname of

the machine hosting the reverse proxy/load balancer. **Note:** do not complete this field unless you have at least one host machine address.

4. *Host machine for reverse proxy / load balancer (optional)*: required, in this case. All inbound (connector to tunnel) traffic is routed to an NGINX-based reverse proxy/load balancer deployed to this host machine during installation of the connector.

5. Connector replicas: configure the tunnel connector replicas to set High Availability.

5. In the *Secure Tunnel setting*, configure the tunnel worker replicas to set High Availability, limit: 1-16.

6. *HTTPS proxy*: optional. Specify a forward proxy to enable the Secure Tunnel to reach the connector in the other network, such as username:password@hostname:port.

   Note: It is necessary to enter the HTTPS proxy information when Secure Tunnel is in an air-gapped environment. If your Secure Tunnel is in an air-gapped environment without internet connectivity, you need to prepare a host machine (virtual machine or physical machine), and ensure that the host machine can be accessed from the IBM Cloud Pak for AIOps cluster and also can connect to the internet. Then, install an HTTPS proxy server in the host machine, and set the HTTPS proxy server in the HTTPS proxy field.

7. *Allowed list*: Specify the IP addresses and ports that are exposed across this connection through application mappings. You can specify address ranges and port ranges. If you do not define an allowed list, the application mapping URL is inaccessible. To expose the IBM Cloud Pak for AIOps instance, input IBM Cloud Pak for AIOps instance address: **`internal-nginx-svc 12443`**

8. Click **Create connection** to initiate a custom connection. In the *Next steps* page, you install a connector and create application mappings.

2. Follow the Install Secure Tunnel Connector guide to enable the connection.

3. Create *Application Mapping* to expose the applications to another network (Secure Tunnel side to connector side, or opposite). Set application mappings to expose the IBM Cloud Pak for AIOps instance. Go to the **Secure Tunnel Console** on the **Manage connections** tab page, and click the **Application mappings** of the *tunnel connection* list. You are redirected to the *Application mappings* page. The *Application mappings* page can resemble the following screenshot:

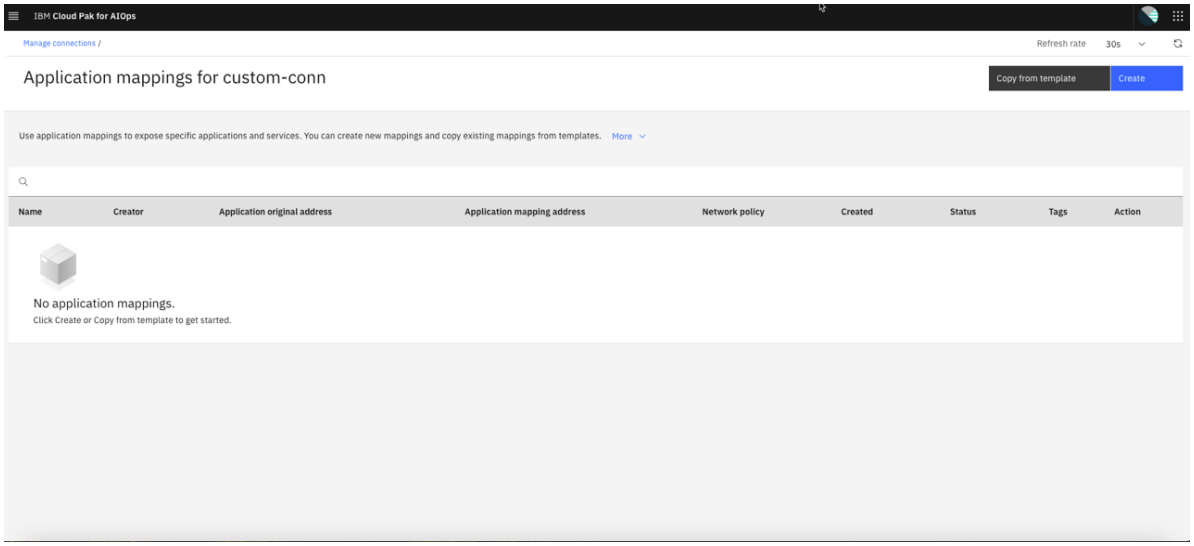

Figure. Create Application Mappings

You have two ways to create a connection:

- *Create a connection from scratch*
- *Create a connection from existing template*.

1. Create a connection from scratch:

   1. Click **Create** to open the panel to create an application mapping from scratch.
      1. In the *Name and Tags* section, provide a name and tags for this application mapping:

         1. Application mapping name: required. The name of the application mapping name can include lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
            1. New tag: optional. The tag of the application. Add a tag **`chatops=true`** in our example.
      2. In *Direction*, specify how you expose the application *from connector side to Secure Tunnel side* or *from Secure Tunnel side to connector side*. Because the IBM Cloud Pak for AIOps instance is in Secure Tunnel side, in this case, choose *from Secure Tunnel side to connector side*.

      3. In the *Application details* section,

         1. Specify the address of the application and the ports that you want to expose. The address and ports must be included in the allowed list for the connection. Configure DNS so that the application can be accessed by using the original address or the application mapping address (optional) . Input the IBM Cloud Pak for AIOps instance address: **`internal-nginx-svc`**, and port: **`12443`**, and the exposed mapping port (default is **`12443`**. Change as you need.). **Note:** Before you add an IP address or hostname, check the existing application mappings from the *Application mappings* page in the IBM Cloud Pak for AIOps console. Check for an existing application mapping. If one is available, check whether the original address is the same IP address or hostname as the new one that you want to specify. Edit the existing mapping to add the new port value instead of creating another application mapping.

         2. *DNS*: Configure DNS so that application can be accessed by using the original address or application mapping address.

3. If you choose to expose the application *from the connector side to the Secure Tunnel side* in the *Direction* section, you can optionally configure the **Reverse proxy**. Toggle each switch to *Yes* to enable the following:

    - *Origin application uses HTTP/HTTPS, and server will check hostname or respond to other URLs of application through HTTP response payload* (for example, Falcon LogScale)
    - *Origin application uses HTTPS* (for example, OpenStack)
    - *Origin application responds to other URLs of application through HTTP response payload* (for example, OpenStack)

4. In *Security*, you can create a Secure Tunnel generic webhook connection. If this is not required, do not switch it on.

5. In *Access rule*, you can use access rules to control the traffic flow at the IP address or port level for particular applications in your cluster. The default network policy allows all ingress and egress traffic for each application mapping. *Network policy*: Network policies help you specify how a pod is allowed to communicate with various network "entities" over the network. Network policies apply to a connection with a pod on one or both ends, and are not relevant to other connections.

2. Create a connection from existing template:

    1. Click **Copy from template** button, and the new page opens.

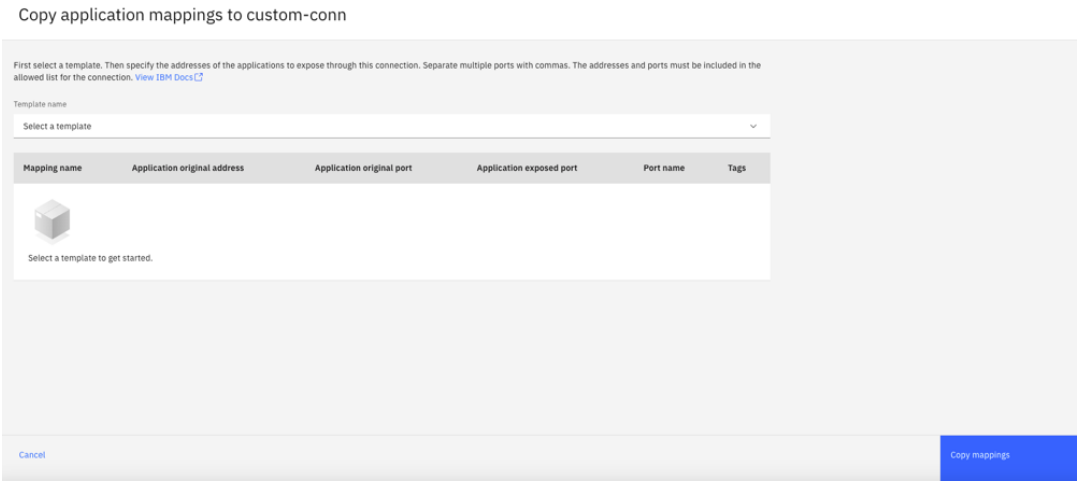

Figure. Copy Application Mappings

    2. Choose a **template**. You can see the application mappings in this template is displayed in the table.

    3. In the table, you can edit the *Application Mapping name*, *Application original address*, *Application original Port* and *Application exposed port*

    4. Click **Copy mappings** to create application mappings through this connection.

4. Now you have successfully exposed the application as you need. In our example, IBM Cloud Pak for AIOps is exposed to the public network, so you can use the application mapping address to access IBM Cloud Pak for AIOps.

Creating a Custom Instana connection

1. Ensure that your cluster has the following prerequisites installed and configured:

    - An Instana server is installed and runs in an Red Hat OpenShift Container Platform cluster.
    - An IBM Cloud Pak for AIOps cluster is installed and runs in a public cloud with Secure Tunnel enabled.

2. Create the secure tunnel connection for Instana

    1. From the IBM Cloud Pak for AIOps console main navigation menu, click **Administration** > **Secure Tunnel**.
    2. In the *Secure Tunnel* page, click **Create connection**.
    3. Click the **Create connection** link under *Custom* section and then click **Get started**.
    4. On the *Name and tags* page, input a name in *Connection name* field, for example `instana-via-tunnel`, click **Next**.
    5. Choose **Connector in private network initializes connection to Secure Tunnel in public network** in *Direction*, click **Next**.
    6. On *Connector settings* page, choose **Host machine**. Input the hostname or IP address of the host machine where you installed the Secure Tunnel connector. Click **Add** > **Next**.
    7. On *Secure Tunnel settings* page, click **Next**.
    8. On *Allowed list* page, input the IP address and port of Instana server, for example `9.46.108.75` and `443`, click **Add** button and click **Create connection**.
    9. Wait for the *Next steps* page display, click **Close**.
    10. Download the Secure Tunnel Connector Installation package by using one of the following options:
        - If you are still in the `Next steps` page, you can download the installation package by clicking download link under *Install a connector*
        - If you are not in the `Next steps` page yet, navigate to *Manage Connection* page, find the `to-instana-through-ocp` row, and click the three dots in the **Actions** column, then click **Install connector** link. You can now download the installation package by clicking the download link in the open panel.

3. Install Secure Tunnel Connector to a host machine

    1. refer to Install the Secure Tunnel Connector to a host machine (virtual machine or physical machine)
    2. On the *Secure Tunnel* page, the *Status* column of `instana-via-tunnel` connection is green.

4. Create Application Mapping to expose Instana:

    1. From the Cloud Pak for AIOps console navigation menu, click **Administration** > **Secure Tunnel**.

2. On the *Secure Tunnel* page, click the **Application mapping** column on the row `instana-via-tunnel`.
3. On the *Application mappings for instana-via-tunnel* page, click **Create** button.
4. On the *Create application mapping* page, click **Next**.
5. On the *Name and tags* page, input a name, for example `instana` then click **Next**.
6. On *Direction* page, choose **From connector side to Secure Tunnel side** and click **Next**.
7. On *Application details* page, input Instana server IP address and port, for example `9.46.108.75` and `443` and click **Add** button.
8. On *Access rules (optional)* page click **Create**.
9. On the *Application mappings for instana-via-tunnel* page, wait for a few minutes, then the `Status` column of `instana` row become `Ready`.
10. In the *Application mapping address* column, click the **information button(a circle with an `i` in it)**, and copy the address in the open message. For example, `sre-tunnel-c60f3456bad94a10-svc.cp4waiops:443`. Save it to a note pad.

5. Create an Instana connection

1. From the Cloud Pak for AIOps console navigation menu, click **Define** > **Integrations**.
2. On the Integrations, click **Add integration** button.

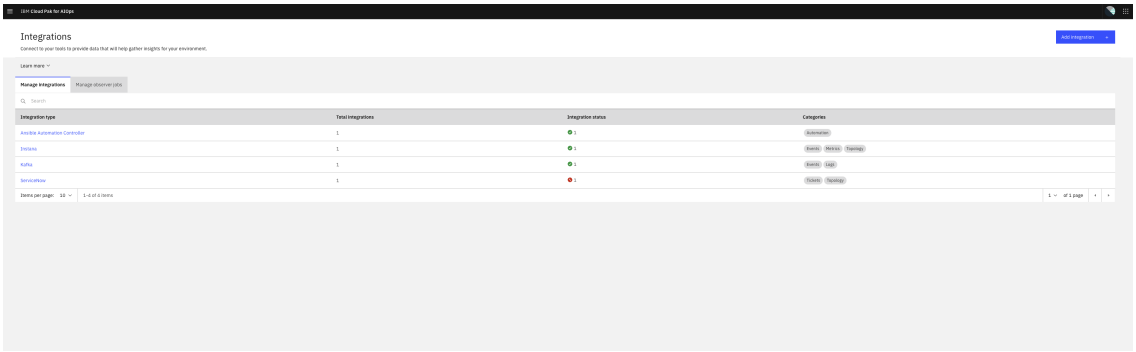

Figure. Add integration

3. On the *Add connections* page, search for *Instana*, click the *Instana* tile, and then click **Connect** button.
4. On the Instana *Add integration* page, add the following:
    1. *Name*, for example `tunnel-2-instana-public`
    2. *Description*, for example `Connect to an Instant in public cloud through the Secure Tunnel`
    3. *Endpoint*, by using the `Application mapping address` copied from Secure Tunnel Application Mapping, for example `https://sre-tunnel-c60f3456bad94a10-svc.cp4waiops:443`.
    4. *API Token*, by using the API Token find from your Instana server, for example `W6p9WimUT5aYQ_skNu0W9A`
    5. *Deployment options*, Local deployment or remote deployment.
        - Local: Deploy the integration in the same cluster and namespace where Cloud Pak for AIOps is installed.
        - Remote: Deploy the integration anywhere you choose, for example, a different network region, on SaaS, or remote on-premises (VM, cluster, container etc).
    6. Click **Next**
5. On the *Configure* proxy page, enable or disable the proxy.
6. On the *Collect topology data* page, click **Next**.
7. On the *Collect event data* page, click **Next**.
8. On the *Collect metric data* page, click **Done**. You are redirected to the *Instana* connection page.

    Your new connection is listed in the table on the page. The connection has an intial status of *Initializing*. After a few minutes, the status changes to *Running* if your connection is successful.

6. Verify the Instana Connection

1. From the Cloud Pak for AIOps console navigation menu, click **Operate** > **AI model management**.
2. On the *AI model management* page, click the **Data assets** tab.
3. The **Data flow status** column for the `tunnel-2-instana-public` connection should display a status of *Running*.

Creating a Secure Tunnel Generic Webhook connection

To integrate IBM Cloud Pak for AIOps **Generic Webhook** with a service like New Relic, the IBM Cloud Pak for AIOps instance must be accesible from the public network. If your IBM Cloud Pak for AIOps is not accessible from the public network, you can open the IBM Cloud Pak for AIOps **Generic Webhook** to the public network by creating a Secure Tunnel. You can do this by exposing the IBM Cloud Pak for AIOps **Generic Webhook** to either a cluster (Red Hat OpenShift Container Platform or IBM Kubernetes Service cluster) or a host machine (a virtual machine or a physical machine), which is accessible from the public network. You can create the **Generic Webhook** Secure Tunnel from the **Secure Tunnel Console** on the **Manage connections** page.

To create a Secure Tunnel generic Webhook connection, complete the following steps:

1. Create the generic webhook connection with the IBM Cloud Pak for AIOps console. For more information, see Creating Generic Webhook connections.

    As you are creating the connection, copy the *Webhook route*. The Webhook route can resemble the following example route:

    `https://whconn-f78d2a04-c881-40c1-a8cc-f329a297b7f6-cp4waiops.apps.katui.cp.fyre.ibm.com/webhook-connector/h35qpu67hjh`

    The part `f78d2a04-c881-40c1-a8cc-f329a297b7f6` is the *Webhook uuid* and the part `/webhook-connector/h35qpu67hjh` is the *Webhook route path*.

2. Log in to the IBM Cloud Pak for AIOps cluster and then execute below command to get the **certificate CA** of the *Generic Webhook* service.

   ```
   oc -n <the namespace of the IBM Cloud Pak for AIOps> get ConfigMap ibm-grpc-webhook-connector-ca-cert-<Webhook uuid> -o=jsonpath='{.data.service-ca\.crt}'
   ```

   For example execute *oc -n aiops get ConfigMap ibm-grpc-webhook-connector-ca-cert-f78d2a04-c881-40c1-a8cc-f329a297b7f6 -o=jsonpath='{.data.service-ca.crt}'*

3. Follow the Custom connection instructions to create a **`Secure Tunnel in private network initializes connection to connector in public network`** direction Tunnel Connection and install the Secure Tunnel Connector.

   Note:

   - In the *Direction* section, select the **`Secure Tunnel in private network initializes connection to connector in public network`** radio button.
   - In the *Allowed list* section, add **`webhook-connector-<Webhook uuid>.<the namespace of the IBM Cloud Pak for AIOps>.svc.cluster.local 443`** (for example, **`webhook-connector-f78d2a04-c881-40c1-a8cc-f329a297b7f6.aiops.svc.cluster.local 443`**) to the *Allowed list*.
   - If you want to install the connector in the Cloud, specify a publicly accessible cluster with a CA-signed domain certificate.
   - If you want to install the connector on the Host machine, ensure you have a signed trusted certificate for this Host machine.

4. Create an **Application Mapping** to expose the IBM Cloud Pak for AIOps **Generic Webhook** service to the public network.

   1. Go to the Secure Tunnel Console on the Manage connections tab page, and click the **Application mappings(valid/total)** of the tunnel connection list. You are redirected to the **Application mappings** page.
   2. Click **Create** to open the panel to create an application mapping from scratch.
      1. In the *Name and Tags* section, provide a name and tags for this application mapping:
         - *Application mapping name:* required. The name of the application mapping name can include lowercase alphanumeric characters and '-', and must start and end with a lowercase alphanumeric character.
         - *New tag:* optional.
      2. In the *Direction* section, select **From Secure Tunnel side to connector side**.
      3. In the *Application details* section, add the endpoint that is in the allowed list, (for example **`webhook-connector-f78d2a04-c881-40c1-a8cc-f329a297b7f6.aiops.svc.cluster.local`**) to the **IP address or hostname** and **`443`** to the **Port**. You can update the **Exposed mapping port** to change any no-conflict valid port that you want.
   3. Click the **Add** button.
      1. In the *Security* section, choose **Yes** for the **Enable security for the exported application which is HTTP protocol.**.
      2. *Select termination type:* select *Reencrypt*.
         - If you want to install the connector in the Cloud, **Destination CA certificate** the **certificate CA** of the **Generic Webhook** service.
         - If you want to install the connector in the Host machine:
            - *Certificate:* the **`cert`** of the signed trusted certificate of the Host machine.
            - *Private key:* the **`key`** of the signed trusted certificate of the Host machine.
            - *Destination CA certificate:* the certificate CA of the Generic Webhook service.

5. Get the exposed **Webhook** URL to integrate with a service like **New Relic**. From the Secure Tunnel *Application Mapping* list UI page, get the **Application mapping address** for example **`https://secure-tunnel-connector.fyre.ibm.com:443`**.

   You can then integrate the **Generic Webhook** with a service like **New Relic** with the URL **`<Application mapping address><Webhook route path>`** (for example **`https://secure-tunnel-connector.fyre.ibm.com:443/webhook-connector/h35qpu67hjh`**).

Viewing Secure Tunnel

With the Secure Tunnel tool in the IBM Cloud Pak for AIOps console, you can get the application mapping URL that can be accessed by your integration. In addition, you can view the configuration details and status of all tunnel connections and application mappings. If you have not accessed the Secure Tunnel web console previously, read this.

- Secure Tunnel Components
- Viewing tunnel connection list
- Viewing the application mappings
- Certificate expiration

Secure Tunnel Components

There are four components on the Secure Tunnel page in the console that you can use to manage your connections. To access these, go to **Administration** > **Secure Tunnel**.

- **Manage connections**

  Use **Manage connections** to manage your connections to remote networks, A connection links the network containing the Secure Tunnel to a remote network. Your applications can reside on either side of the connection. Secure Tunnel includes connection templates for common scenarios(ChatOps, VMware, Turbonomic). You can also create custom connections to support additional scenarios.

- **Manage templates**

  Use **Manage templates** to manage your templates. This tool can help you create a new connection quickly. Secure Tunnel has pre-defined templates for common scenarios, but users can also create templates for their special requirements. Find out more about using templates

- **Audit operations**

Use **Audit operations** to check Secure Tunnel configuration changes, such as tunnel connection or application mapping configuration changes for auditing. Find out more about auditing Secure Tunnel

- **Audit traffic**

  Use **Audit traffic** to check open/close connection events traffic and see the total amount of data that is sent or recieved from the specific connection listed in the close event. Find out more about auditing Secure Tunnel

Viewing tunnel connection list

Go to **Administration** > **Secure Tunnel**. In the *Manage connections* page, you can see the tunnel connection list with the following columns:

- **Name**: Name of the tunnel connection. Click the name of the tunnel connection in the *Manage connections* page and you are redirected to the *Application mappings* page and the *Connection details* page.
- **Connectors**: The number of connections. This indicates how many Connectors connect to the tunnel worker.
- **Application mapping(valid/total)**: The number of valid application mappings and the total number of application mappings that are passing this connection. You can click the entry in this column to go to the application mappings page for more details. See Viewing the application mappings.
- **Direction**: The relationship between the Secure Tunnel and the Connector. A Connector in a private network initializes a connection to a Secure Tunnel in a public network or a Secure Tunnel in a private network initializes a connection to a Connector in a public network
- **Allowed list**: The IP addresses and ports that are exposed across this connection by using application mappings.
- **Created**: The date and time when the Connector was created.
- **Certificate expiration**: Expiration time of certificates.
- **Status**: Indicates whether the tunnel connection is accessible. Three kinds of status are provided:
  - `Pending`: This means that the tunnel connection is creating the tunnel worker. When the connection in in `Pending` status, you can't install the Connector for the connection.
  - `Waiting`: This means that tunnel worker is ready, but no Connector is connecting to it. You need to install a Connector and create application mapping for this connection.
  - `Ready`: This means that the connection is ready.
  - `Error`: This means that there are some errors with the tunnel connection. Hover over the status to see the detailed error message.
  - `Incomplete`: This means that the application mapping for the connection is invalid.
- **Tags**: Used to signify the tunnel connection.

Viewing the application mappings

Go to **Administration** > **Secure Tunnel**. This opens the *Manage connections* page. Click the number in the **Application mappings (valid/total)** column. You are redirected to the *Application mappings* page. This provides details of all the application mappings of a connection.

- **Name**: Name of the application mapping.
- **Creator**: User that creates the application mapping.
- **Application original address**: The private address of the application that you want to expose.
- **Application mapping address**: The application mapping URL. You can access the private application by this mapping address.
- **Network policy**: To control the traffic flow at the IP address or port level for this application.
- **Created**: Time when the application mapping was created.
- **Status**: Indicates whether the application mapping is accessible. Three kinds of status are provided:
  - `Error`: This means that there are some errors with the application mapping. You can move the mouse up to see the detailed error message.
  - `Incomplete`: If the application mapping status is `Incomplete`, hover your mouse pointer over the *Status* column to discover the problem. It could be that you did not install the Connector or that Connector is still waiting to connect. If a port conflict is indicated, uninstall the Tunnel connector, resolve the port conflict, and then re-install the Tunnel connector.
  - `Ready`: This means that the application mapping address is accessible.
- **Tags**: Tags of the application mapping.

Certificate expiration

When the certificate for the Secure Tunnel connection expires, the IBM Certificate Manager renews it. The Secure Tunnel worker server automatically reloads the certificate, but the Secure Tunnel connector does not. You must download a new Secure Tunnel connector installation script, and then uninstall and reinstall the Secure Tunnel connector. For more information, see the instructions in Install the Secure Tunnel Connector.

Modifying Secure Tunnel

In the Secure Tunnel web console you can modify the configurations for a tunnel connection and application mapping to meet your needs. (Read this if you have not used Secure Tunnel web console previously).

- Configuring tunnel connections
- Managing Template
- View Template
- Delete Template
- How to obtain the application mapping address

Configuring tunnel connections

- **Configuring tunnel connections**
  - **Edit connection**: To modify the connection, locate the connection, and click **Action** > **Edit** connection.
  - **Renew certification**: To renew the certificate of the tunnel connection, locate the connection, and click **Action > Renew** certificate. Then, the certificate of the tunnel connection is updated, and the certificate expiration time field is changed.
  - **Delete connection**: To delete a tunnel connection, locate the connection, and click **Action > Delete connection**.
- **Configuring application mapping**
  - **Edit application mapping**: To edit the application mapping, locate the application mapping, click **Action > Edit**.
  - **Delete application mapping**:To delete the application mapping, locate the application mapping, and click **Action > Delete**.
- **Installing Secure Tunnel connector**
  - Follow this guide

Managing Connection Templates

A template includes pre-defined connection settings and one or more application mappings. Examples of pre-defined templates available in IBM Cloud Pak for AIOps are ChatOps and Vmware, which you can access in **Manage connections** > **Create connection**.

You can use a template to quickly create a new connection, or to add application mappings to an existing connection. You can easily modify the application mappings to meet the unique requirements of the connection.

Create Template

Click **Create template** button to open the page:

1. Provide a name and a description for this template.
2. Select the connection upon which the template is based.
3. Select the application mappings for the template.

Once you create a template, you can use it to simplify the creation of future connections.

View Template

Click **Action** in the template column. Then, click **View details** to view the template details.

Delete Template

Click **Action** on the template column. Then, click **Delete** to delete the template.

How to obtain the Application URL mapping address

1. From the Secure Tunnel console, select **Manage connections** tab.
2. Click the **Application mappings** item of the tunnel connection.
3. Choose the **Application mapping** by name from the **Application mapping** list page.
4. Then, copy the address from the **Application mapping address** item.

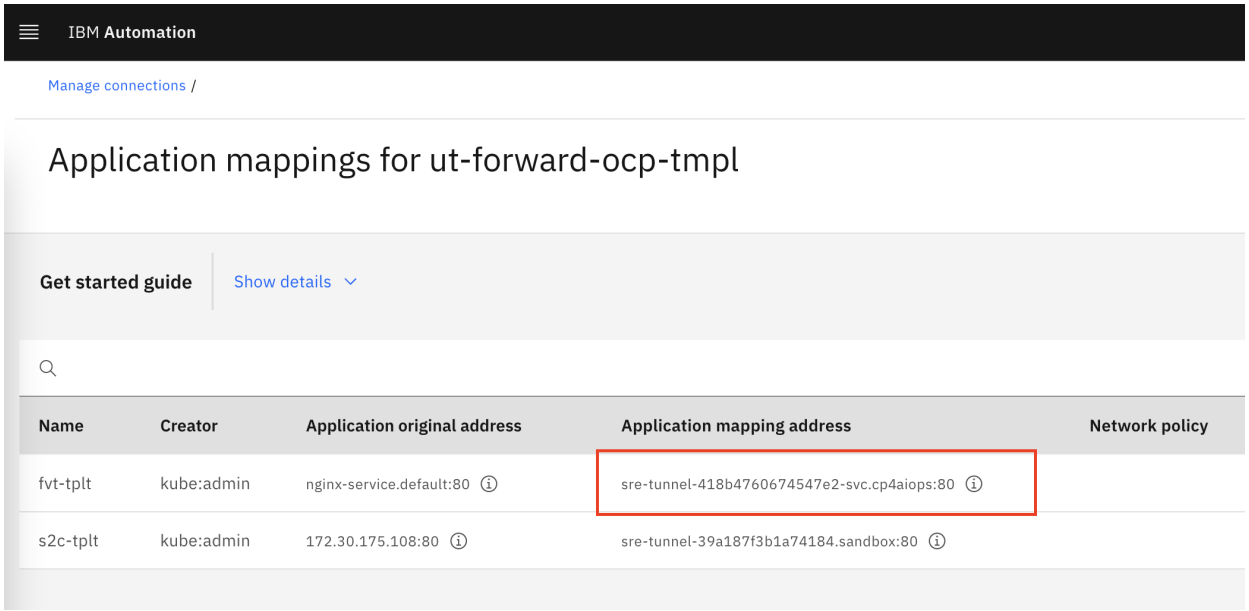

Figure. Application mapping

Auditing Secure Tunnel

You can check Secure Tunnel configuration changes, such as tunnel connection or application mapping configuration changes for auditing.

How to audit Secure Tunnel

Go to **Administration** > **Secure Tunnel** on IBM Cloud Pak for AIOps console. You see the **Audit operations** and **Audit traffic** tabs.

1. In the *Audit operations* tab, you can see the operation logs, such as deleting a tunnel connection or creating a tunnel connection. You can filter the logs by changing the start time and end time in the **Start time** and **End time** fields.

   Note: You can click the **Operation details** column to see more about the tunnel operation.

2. In the *Audit traffic* tab, the tunnel **`open/close`** connection events are listed, and a total **`send/receive`** data amount for the specific connection is listed in the **`close`** event. You can filter the logs by changing the start time and end time in the **Start time** and **End time** fields.

Configuring Secure Tunnel audit logs

Secure Tunnel can send audit logs to its container log, a MongoDB database, and a remote syslog server. By default, Secure Tunnel sends audit logs to its container log, and thus you can't see audit logs on the Secure Tunnel console. To check audit logs on the Secure Tunnel console, you need to send audit logs to MongoDB. To check audit logs on the query user interface of a specific syslog, you need to send audit logs to the remote syslog server.

Configuring with the operator UI when creating a Secure Tunnel installation

1. When you create the Secure Tunnel instance from your OpenShift console, click **Operators** > **Installed Operators**.
2. From the ***Project** menu, select the project that you want to create the Secure Tunnel instance in. Use the project that you created earlier in **Create a Secure Tunnel project (namespace)**.
3. Select **IBM Secure Tunnel** operator.
4. Click **Create Installation** on the *Tunnel* box. The default **Form View** is displayed. Edit the **Audit logs** to configure the audit log receivers of the Secure Tunnel:
5. *Show audit logs in the container log:* If the Secure Tunnel should send audit logs to its container log(the pod terminal).
6. *Audit Receiver:* to add a **MongoDB audit log receiver** or a **Syslog audit log receiver**

   1. Click the **MongoDB receiver** > **Add MongoDB receiver** button. To add a **MongoDB audit log receiver** > click **MongoDB Information**. Enter the following values:

      1. *Receiver name:* The name of the MongoDB receiver, it's the unique name of the audit log receiver. for example: **`mongodb-receiver-1`**.
      2. *TLS Secret:* if you want the MongoDB to support TLS, you should create a TLS Kubernetes secret for the MongoDB TLS certification, and enter the *k8s secret name* to here. the Kubernetes secret should be in the Secure Tunnel namespace and contain the "ca.crt", "tls.crt" and "tls.key" of the mongoDB TLS. TLS secret example:

```
kind: Secret
apiVersion: v1
metadata:
name: mongodb-tls-certificate
namespace: tunnel-stand-alone
data:
ca.crt:
LS0tLS1CRUdJTiBDRVJUSUZJQ0FURS0tLS0tCk1JSURDVENDQWZHZ0F3SUJBZ0lRTjRtVDZOTFgxZjF1K0pSVFR4LzRoakFOQmdrcWhraU

0tLS0tCg==
type: kubernetes.io/tls
```

3. *Database name:* The database name of the MongoDB receiver, for example: **mongodb-audit-log-receiver-1**
4. *Address:* The MongoDB receiver address. For example: **<IP or hostname>:27017**
5. *MongoDB log in Username, Password Secret:*
    1. By default, MongoDB does not require a username and password to access, but it can be enabled by configuring the authentication. If the MongoDB has a username and password, you should create a Kubernetes secret that contains **user: <MongoDB username>** and **password: <MongoDB password>** in the Secure Tunnel namespace, then enter the secret name here.

       Kubernetes secret example:

       ```
       kind: Secret
       apiVersion: v1
       metadata:
         name: mongodb-credential
         namespace: tunnel-stand-alone
       data:
         password: YmJiYg==
         user: YWFhYQ==
       type: Opaque
       ```

2. Click **Syslog receiver** > **Add Syslog receiver** to add a **Syslog audit log receiver**, Enter the following values:

- *Receiver name:* the name of the Syslog receiver. It's a unique name of the audit log receiver. for example: *syslog-receiver-1*.
- *Address:* The syslog server address. for example: **<IP or hostname>:5514**

Configuring YAML to update the existing Tunnel instance

1. From the Openshift console, click **Operators** > **Installed Operators**.
    - From the **Project** dropdown menu, select the project that you created the Secure Tunnel instance in.
    - Click the **IBM Secure Tunnel** > **Tunnel** tab > click the existing **sre-tunnel** instance > change to **YAML** tab.
2. For Secure Tunnel to send audit logs to its container log, configure the **YAML** file:

```
spec:
  ...
  showInContainerLog: true
  ...
```

3. For Secure Tunnel to send audit logs to MongoDB, configure the **YAML**:

```
spec:
  ...
  auditReceiver:
    mongoDB:
      - mongoAddress:
          mongoAddress: '<IP or hostname that the MongoDB running in>:27017'
          mongoDatabaseName: secure-tunnel-001
          name: mongodb-audit-log
          passwordSecretName: <The name of the Kubernetes secret that saved the MongoDB username and password>
          tlsSecret: <The name of the Kubernetes secret that saved the SSL certificate of the MongoDB service>
  ...
```

4. For Secure Tunnel send audit logs to a remote syslog server, configure the **YAML**:

```
spec:
  ...
  auditReceiver:
    syslog:
      - name: syslog
        syslogAddress: '<IP or hostname that the Syslog service running in>:5514'
  ...
```

Tip: It's easier to configure the audit log with the Configuring with the operator UI when create Secure Tunnel Installation method, so you can configure it from there. Switch to the **YAML view**, obtain the configuration yaml and update the existing Secure Tunnel instance yaml to configure the audit log.

Updating the deployment type (IBM Cloud Pak for AIOps on OpenShift)

Learn how to switch between the base deployment and extended deployment types.

Overview

After IBM Cloud Pak® for AIOps is installed, you can change your deployment type from a base deployment to an extended deployment, or from an extended deployment to a base deployment. For more information about the base deployment and extended deployment types, see Incremental adoption.

If you have log or ticket integrations configured that require an extended deployment, you are prevented from changing to a base deployment until these integrations are removed.

Important: If you are changing from a base deployment to an extended deployment, ensure that you meet the additional hardware requirements. For more information, see Hardware requirements.

You can change your deployment type with the Red Hat® OpenShift® Container Platform console or CLI.

Switching deployment type with the Red Hat OpenShift console

1. From your Red Hat OpenShift console, click **Operators** > **Installed Operators**.
2. From the **Project** dropdown menu, select the project that IBM Cloud Pak for AIOps is deployed in.
3. Select the **IBM Cloud Pak for AIOps** operator, then click the **IBM Cloud Pak for AIOps** tab.
4. Click the IBM Cloud Pak for AIOps deployment that is displayed in the **Installations** section, and then switch to the **YAML** view.
5. If the section **spec** > **pakModules** > **logAnomalyDetection** does not exist, then add it. Otherwise, find and edit the `logAnomalyDetection` section under **spec** > **pakModules**.

   Set the value of **enabled** to one of the following options and then click **Save**:

   - `false` for a base deployment without log anomaly detection and ticket analysis capabilities.
   - `true` for an extended deployment with log anomaly detection and ticket analysis capabilities.

   Example `pakModules` excerpt for a base deployment:

```
pakModules:
 - enabled: true
   name: aiManager
 - enabled: true
   name: aiopsFoundation
 - enabled: true
   name: applicationManager
 - enabled: false
   name: connection
 - enabled: false
   name: logAnomalyDetection
```

   Example `pakModules` excerpt for an extended deployment:

```
pakModules:
 - enabled: true
   name: aiManager
 - enabled: true
   name: aiopsFoundation
 - enabled: true
   name: applicationManager
 - enabled: false
   name: connection
 - enabled: true
   name: logAnomalyDetection
```

   Warning: The pakModules `aiManager`, `aiopsFoundation`, and `applicationManager` must be enabled as in the preceding YAML. Do not change these values to false.

Switching deployment type with the Red Hat OpenShift CLI

1. Ensure that you are logged in to your Red Hat OpenShift cluster with `oc login`.
2. Set environment variables.

```
export AIOPS_NAMESPACE=<project>
export AIOPS_INSTANCE=$(oc get installation -o jsonpath='{.items[0].metadata.name}' -n ${AIOPS_NAMESPACE})
```

   Where `<project>` is the namespace (project) that your IBM Cloud Pak for AIOps installation is deployed in.

3. Edit your IBM Cloud Pak for AIOps `installation` instance by running the following command:

   ```
   oc edit installation ${AIOPS_INSTANCE} -n ${AIOPS_NAMESPACE}
   ```

4. If the section **spec** > **pakModules** > **logAnomalyDetection** does not exist, then add it. Otherwise, find and edit the `logAnomalyDetection` section under **spec** > **pakModules**.

   Set the value of **enabled** to one of the following options and then click **Save**:

   - `false` for a base deployment without log anomaly detection and ticket analysis capabilities.
   - `true` for an extended deployment with log anomaly detection and ticket analysis capabilities.

   Example `pakModules` excerpt for a base deployment:

   ```
   pakModules:
    - enabled: true
      name: aiManager
    - enabled: true
      name: aiopsFoundation
    - enabled: true
      name: applicationManager
    - enabled: false
      name: connection
    - enabled: false
      name: logAnomalyDetection
   ```

   Example `pakModules` excerpt for an extended deployment:

   ```
   pakModules:
    - enabled: true
      name: aiManager
    - enabled: true
      name: aiopsFoundation
    - enabled: true
      name: applicationManager
    - enabled: false
      name: connection
    - enabled: true
      name: logAnomalyDetection
   ```

   Warning: The pakModules `aiManager`, `aiopsFoundation`, and `applicationManager` must be enabled as in the preceding YAML. Do not change these values to false.

Uninstalling IBM Cloud Pak for AIOps on OpenShift

These instructions can be used to uninstall an online or offline (airgap) deployment of IBM Cloud Pak® for AIOps, and to clean up the resources that it created.

1. Run the uninstall script
2. (Optional) Delete the IBM Cloud Pak for AIOps catalog
3. (Optional) Delete the Cert Manager
4. (Optional) Delete the License Service

Before you begin

The Red Hat® OpenShift® Container Platform command line interface (`oc`) must be installed on your Red Hat OpenShift cluster, and you must be logged in with `oc login`.

1. Run the uninstall script

Download the uninstall and cleanup script from github.com/IBM.

You can configure the script to uninstall and clean up your IBM Cloud Pak for AIOps deployment. Details on how to configure the script are provided in the same location.

You can configure the script to remove specific components and resources. Remove the following resources only if you are sure that they are not used by other CloudPaks on your Red Hat OpenShift cluster, and you do not want to persist the data.

- Persistent Volume Claims (PVCs)
- shared components that are used by other Cloud Paks

Important: If the script appears to be stuck and 1.5 hours has elapsed, then contact IBM Support for assistance in safely cleaning up your environment. Do not manually delete resources.

Example output:

```
# ./uninstall-cp4waiops.sh -s
[INFO] Uninstall v2.0 for AIOPs v4.8

[SUCCESS] ----Congratulations! IBM Cloud Pak for AIOps has been uninstalled!----
```

2. (Optional) Delete the IBM Cloud Pak for AIOps catalog

If you do not require the IBM Cloud Pak for AIOps catalog **`ibm-aiops-catalog`**, then remove it with one of the following methods:

Online deployments:

- Option 1: Delete the IBM Cloud Pak for AIOps catalog with the Red Hat OpenShift console
- Option 2: Delete the IBM Cloud Pak for AIOps catalog with the Red Hat OpenShift CLI

Air-gapped (offline) deployments:

- Option 3: Delete the IBM Cloud Pak for AIOps catalog in an air-gapped deployment

Option 1: Delete the IBM Cloud Pak for AIOps catalog with the Red Hat OpenShift console

1. In the OpenShift console, select **Administration** > **Cluster Settings**.
2. Select the **Configuration** tab, and then select **OperatorHub** from the **Configuration Resource** column.
3. Select the **Sources** tab.
4. Select the CatalogSource that you want to remove: **`ibm-aiops-catalog`**.
5. Select **Delete CatalogSource** from the **Actions** list (the three vertical dots at the end of the row).
6. Verify that the CatalogSource that you removed is not shown in **Administration** > **Cluster Settings** > **Configuration** > **OperatorHub** > **Sources**.

Option 2: Delete the IBM Cloud Pak for AIOps catalog with the Red Hat OpenShift CLI

1. Run the following command for the catalog that you want to remove.

   ```
   oc delete catalogsource -n openshift-marketplace <catalogsource>
   ```

   Where **`<catalogsource>`** is the name of the CatalogSource that you want to delete: **`ibm-aiops-catalog`**.

2. Verify that the following command doesn't return the catalog that you removed:

   ```
   oc get catalogsource -n openshift-marketplace
   ```

Option 3: Delete the IBM Cloud Pak for AIOps catalog in an air-gapped deployment

Note: If you have an air-gapped deployment of IBM Cloud Pak for AIOps that was initially installed at a version lower than 3.5, then follow the instructions for **`Option 3: Delete the AI Manager catalog in an upgraded air-gapped deployment`** in the IBM Cloud Pak for AIOps 3.5 documentation: Uninstalling IBM Cloud Pak® for AIOps IBM Cloud Pak for AIOps.

If you have an air-gapped deployment of IBM Cloud Pak for AIOps, then remove the catalog by using the **`uninstall-catalog`** case action.

1. Export the following environment variables.

   The local registry that you specify must be the registry in your air-gapped environment that you created when you installed Cloud Pak for AIOps.

   ```
   export CASE_NAME=ibm-cp-waiops
   export CASE_VERSION=1.14.0
   export CASE_INVENTORY_SETUP=cpwaiopsSetup
   export TARGET_REGISTRY_HOST=<IP_or_FQDN_of_target_registry>
   export TARGET_REGISTRY_PORT=<port_number_of_target_registry>
   export TARGET_REGISTRY=$TARGET_REGISTRY_HOST:$TARGET_REGISTRY_PORT
   ```

2. Run the **`uninstall-catalog`** CASE action.

   ```
   oc ibm-pak launch $CASE_NAME \
   --version $CASE_VERSION \
   --action uninstall-catalog \
   --inventory $CASE_INVENTORY_SETUP \
   --namespace openshift-marketplace \
   --args "--registry $TARGET_REGISTRY --recursive \
   --inputDir ~/.ibm-pak/data/cases/$CASE_NAME/$CASE_VERSION"
   ```

3. Verify that the catalog that you removed is not returned by the following command:

```
oc get catalogsource -n openshift-marketplace
```

If the uninstallation fails, or is not complete and is not progressing, then see Troubleshooting installation and upgrade to help you identify any problems.

3. (Optional) Delete Cert Manager

If you installed the IBM Cloud Pak® foundational services Cert Manager, and no other IBM Cloud Paks® are using it, then you can remove it.

1. Follow the instructions in Manual steps for uninstalling singleton services - Cert Manager in the IBM Cloud Pak foundational services documentation.
2. If you have an air-gapped deployment, remove the IBM Cloud Pak foundational services Cert Manager catalog.

```
oc delete catsrc -n openshift-marketplace "ibm-cert-manager-catalog"  --ignore-not-found
```

4. (Optional) Delete the License Service

If you installed the IBM Cloud Pak foundational services License Service, and no other IBM Cloud Paks® are using it, then you can remove it.

1. Follow the instructions in Uninstalling License Service in the IBM Cloud Pak foundational services documentation.
2. If you have an air-gapped deployment, remove the IBM Cloud Pak foundational services License Service catalog.

```
oc delete catsrc -n openshift-marketplace "ibm-licensing-catalog" --ignore-not-found
```

Infrastructure Automation

To learn more about installing and using Infrastructure Automation, see the following topics in the documentation section for Infrastructure Automation.

- Infrastructure automation
  - Planning
  - Installing
  - Upgrading
  - Administering
  - Infrastructure Management
  - Uninstalling

Defining integrations

You can use the IBM Cloud Pak for AIOps console to define integrations and applications.

The integrations and applications that you create serve as the basis for:

- Incoming information that is used to model your IT infrastructure
- Observers that monitor your virtual environments
- Outgoing information that notifies you of any issues

IBM Cloud Pak for AIOps includes many available pre-built integrations that you can configure. If the available integrations do not meet directly meet your requirements, you can use the custom, webhook, and REST integrations to help you create your own integration, such as to integrate with other third-party systems (Blazemeter, Thousand eyes, Catchpoint). In addition you can create custom integrations using the integration SDK.

For more information about defining different types of available integrations in IBM Cloud Pak for AIOps, see the following topics:

- Planning data loading, checking and training
- Mapping data
- Configuring Integrations
- Defining observer jobs

For more informaiton about using the custom integration capabilities, see:

- Creating custom integrations (for log integrations)
- Creating Kafka integrations (for log, event integrations)
- Creating Generic Webhook integrations (for event integrations)
- Creating REST integrations (for topology, resource, application data integrations)
- Creating custom integrations using the integration SDK.

Available integrations

Use this information to see all the integrations that are available.

IBM Cloud Pak for AIOps provides many connectors, probes, and observers by default for setting up integrations with common IBM and third-party systems and services. In addition, if a default integration is not available for connecting to a system or service that you want to use with IBM Cloud Pak for AIOps, you can set up a custom integration to connect to that system or service. For more information about setting up a custom integration, see Creating custom integrations

Note: Each integration that you configure requires an additional 1 vCPU and 3GB memory. For example, if you configure five integrations then you will require an additional 5 vCPUs and 15GB memory.

All available integrations

Click the integration name to learn more about creating, editing, and deleting a particular integration, or about defining an observer job.

Integrations by class

- General (connector) integrations
- Event Manager (probe) integrations
- Observer integrations

- Custom integrations

Netcool integrations

IBM Cloud Pak for AIOps can integrate with IBM Tivoli Netcool/OMNIbus and IBM Tivoli Netcool/Impact to leverage existing event data (IBM Tivoli Netcool/OMNIbus), and policies (IBM Tivoli Netcool/Impact).

With these integrations in place IBM Cloud Pak for AIOps provides AI and visualization features in a modernized UI with an IBM Tivoli Netcool/OMNIbus integration providing additional data and an IBM Tivoli Netcool/Impact integration providing additional automation. You can continue to take advantage of all of your alerts and integrations for IBM Tivoli Netcool/OMNIbus and IBM Tivoli Netcool/Impact to obtain and send data.

Note: Each Netcool integration that you configure requires an additional 1 vCPU and 3GB memory. For example, if you configure three Netcool integrations then you will require an additional 2 vCPUs and 6GB memory.

Integrating with IBM Tivoli Netcool/OMNIbus

You can integrate IBM Cloud Pak for AIOps with an existing IBM Tivoli Netcool/OMNIbus deployment to send event data through the integration to IBM Cloud Pak for AIOps. With this integration, you can see IBM Tivoli Netcool/OMNIbus event data in the IBM Cloud Pak for AIOps Alert Viewer. These events are converted into alerts on the IBM Cloud Pak for AIOps side.

You can then take advantage of the IBM Cloud Pak for AIOps AI features to manage and visualize the alerts. For example, event data can be correlated into incidents, data can be viewed and analyzed in a topology, and runbooks can be used to automate operations for managing the alerts.

To integrate IBM Cloud Pak for AIOps with IBM Tivoli Netcool/OMNIbus, you need to create an IBM Netcool Operations Insight ObjectServer integration with the IBM Cloud Pak for AIOps UI Integrations page. This integration defines the settings for communication from IBM Cloud Pak for AIOps to IBM Tivoli Netcool/OMNIbus. For more information about how to define this integration, see Creating IBM Netcool Operations Insight ObjectServer integrations.

After you integrate with IBM Tivoli Netcool/OMNIbus, use IBM Cloud Pak for AIOps and the IBM Cloud Pak for AIOps UI for AI and visualization features. Use IBM Tivoli Netcool/OMNIbus and the associated UI tools for obtaining and sending data to IBM Cloud Pak for AIOps.

Note: If you have integrated IBM Cloud Pak for AIOps and IBM Tivoli Netcool/OMNIbus, and you are not yet ready to move to using the IBM Cloud Pak for AIOps UI, you can continue to use the IBM Tivoli Netcool/OMNIbus DASH custom dashboards and Web GUI event viewer as you transition to using the IBM Cloud Pak for AIOps UI. If you need to continue to use IBM Tivoli Netcool/OMNIbus tools, you can configure launch-in-context links from the Web GUI Event Viewer and the main DASH navigation to the IBM Cloud Pak for AIOps UI to help users access and use the IBM Cloud Pak for AIOps UI.

Integrating with IBM Tivoli Netcool/Impact

You can integrate IBM Cloud Pak for AIOps with an existing IBM Tivoli Netcool/Impact deployment so that IBM Cloud Pak for AIOps can then run automation policies that you manage with IBM Tivoli Netcool/Impact. New and existing policies can continue to be used to run operations in IBM Tivoli Netcool/Impact for data retrieval, drive automation, create tickets, leverage other integrations with IBM Tivoli Netcool/Impact, and more. These policies can be invoked by IBM Cloud Pak for AIOps or send events to IBM Cloud Pak for AIOps.

IBM Tivoli Netcool/Impact policies can reference the extension framework API for IBM Cloud Pak for AIOps. With these policies, you can write automation processes in IBM Tivoli Netcool/Impact to complete operations in IBM Cloud Pak for AIOps, such as to query alerts and incidents, and request changes to alerts.

In some cases, an event source might have an API through which it can retrieve the events. In this case, IBM Tivoli Netcool/Impact can be employed to retrieve these events. IBM Tivoli Netcool/Impact is commonly used to retrieve data from third-party systems for the purposes of event enrichment. The IBM Tivoli Netcool/Impact policy **`GetHTTP`** function is key for interacting with APIs. For more information about IBM Tivoli Netcool/Impact functions, see List and overview of functions.

To create this integration between IBM Cloud Pak for AIOps and IBM Tivoli Netcool/Impact, you need to first create an IBM Tivoli Netcool/Impact integration with the IBM Cloud Pak for AIOps UI Integrations page. This integration defines the settings for communication from IBM Cloud Pak for AIOps to IBM Tivoli Netcool/Impact. For more information about how to define this integration, see Creating IBM Tivoli Netcool/Impact integrations.

Then to complete the integration, you need to edit the RESTful DSA configuration in IBM Tivoli Netcool/Impact. This configuration defines the settings for communicating from IBM Tivoli Netcool/Impact to IBM Cloud Pak for AIOps. For more information about editing the RESTful DSA configuration, see Configuring an integration in IBM Tivoli Netcool/Impact for IBM Cloud Pak for AIOps.

Key event integrations

IBM Cloud Pak for AIOps deployments might include requirements to integrate with third-party systems, such as a source of information for event enrichment or for ticketing purposes. You can use the following two ways to achieve key event integrations:

- **Events in ObjectServer**: If the nature of the integration is a simple or a one-time action, events can be picked up by IBM Tivoli Netcool/Impact directly from the IBM Tivoli Netcool/OMNIbus ObjectServer. Any updates to the event, such as custom field enrichment or a ticket number can be written back to the event. These updates are propagated to IBM Cloud Pak for AIOps by using the Netcool Connector.
- **Alerts in IBM Cloud Pak for AIOps**: An alternative approach is to create an IBM Cloud Pak for AIOps automation policy that sends the event to IBM Tivoli Netcool/Impact by using the IBM Tivoli Netcool/Impact integration under the preferred criteria. IBM Tivoli Netcool/Impact policy can write any updates or enrichments back to the IBM Tivoli Netcool/OMNIbus ObjectServer or back to IBM Cloud Pak for AIOps directly.

Creating IBM Tivoli Netcool/Impact integrations

You can integrate your existing IBM Tivoli Netcool/Impact policies with IBM Cloud Pak for AIOps through a IBM Tivoli Netcool/Impact integration. This integration connects the IBM Tivoli Netcool/Impact cluster with IBM Cloud Pak for AIOps.

- About this integration
- Before you begin
- Creating IBM Tivoli Netcool/Impact integrations
- Editing IBM Tivoli Netcool/Impact integrations
- Deleting IBM Tivoli Netcool/Impact integrations
- Enriching an incident by using IBM Tivoli Netcool/Impact policy

About this integration

By connecting with IBM Tivoli Netcool/Impact, IBM Cloud Pak for AIOps can then leverage your existing IBM Tivoli Netcool/Impact deployment to run automation policies that you manage with IBM Tivoli Netcool/Impact. New policies that you create in IBM Tivoli Netcool/Impact can reference the extension framework API for IBM Cloud Pak for AIOps. With these policies, you can write automation processes in IBM Tivoli Netcool/Impact to complete operations in IBM Cloud Pak for AIOps, such as to query alerts and incidents, and request changes to alerts.

Note: You can create multiple integrations between IBM Cloud Pak for AIOps and IBM Tivoli Netcool/Impact. Each integration must point to a unique Impact endpoint.

When you create the integration in IBM Cloud Pak for AIOps to IBM Tivoli Netcool/Impact, the integration automatically creates the RESTful DSA data source in IBM Tivoli Netcool/Impact. To complete the integration with IBM Tivoli Netcool/Impact integration after creating the integration in IBM Cloud Pak for AIOps, you need to edit this RESTful DSA data source in IBM Tivoli Netcool/Impact to define your authentication settings for communicating with IBM Cloud Pak for AIOps API. After editing and verifying the authentication settings, you can begin to create and run your automation policies from IBM Tivoli Netcool/Impact.

Note: If the IBM Tivoli Netcool/Impact cluster uses a non-default cluster name ("NCICLUSTER"), the integration might fail to validate the integration. For more information, see Impact integration fails for Impact server with non-default cluster name.

Before you begin

- Ensure that you have IBM Tivoli Netcool/Impact Version 7.1 with fix pack level 33 or later and IBM Cloud Pak for AIOps 4.8.0 installed.
- Obtain the following details for your IBM Tivoli Netcool/Impact deployment:
  - The endpoint for the GUI server (example: https://noi-impact.fyre.ibm.com:16311)
  - The endpoint(s) for the primary Impact server and any secondary servers (example: https://noi-impact.fyre.ibm.com:9081)
  - If Impact is deployed with Event Manager on OpenShift, you can use the `oc describe noi` command to retrieve the endpoints.
  - The username and password for the IBM Tivoli Netcool/Impact administrator (example: impactadmin) for connecting to the IBM Tivoli Netcool/Impact endpoint.
  - The set of CA certificates for IBM Tivoli Netcool/Impact if the endpoint is secured by SSL/TLS. If self-signed this means all the certificates from all the servers.

    You can extract these certificates from your IBM Tivoli Netcool/Impact deployment with `openssl`:

    - For the GUI server (port 16311)

      ```
      openssl s_client -showcerts -servername noi-impact.mycluster.com -connect noi-impact.mycluster.com:16311
      </dev/null
      ```

    - For the backend server (port 9081)

      ```
      openssl s_client -showcerts -servername noi-impact.mycluster.com -connect noi-impact.mycluster.com:9081
      </dev/null
      ```

    To combine multiple certificates (there is a minimum requirement of two) in the integration settings, you can list them sequentially in no specific order. The combined certificates resembles the following structure:

    ```
    -----BEGIN CERTIFICATE-----
    ABCDEfGHIjklMnOPQrSTUVWXYZABCdefghiJ1k2LMNoPQRSTUVwxYZABCDEFGhij
    ... Server 1 ...
    r+wGXNPwrw==
    -----END CERTIFICATE-----
    -----BEGIN CERTIFICATE-----
    ABCDEfGHIjklMnOPQrSTUVWXYZABCdefghiJ1k2LMNoPQRSTUVwxYZABCDEFGhij
    ... Server 2 ...
    ZYXWVUTSRqpoNnLKJiHGFEDCBAZYXwvutsrQ1p4ONMlKJIHGFEdcBAZYXWVUTsrq
    -----END CERTIFICATE-----
    ```

Creating an IBM Tivoli Netcool/Impact integration

To create an IBM Tivoli Netcool/Impact integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.

2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **IBM Tivoli Netcool/Impact** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section (Events).
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
   - **GUI Server URLs of Impact endpoint**: Enter the GUI URL or URLs for the endpoint. For high availability environments with multiple URLs, enter the URLs as a comma-separated list. For example, `https://impact-1, https://impact-2`.
   - **Backend Server URLs of Impact endpoint**: Enter the backend URL or URLs for the endpoint. For high availability environments with multiple URLs, enter the URLs as a comma-separated list. For example, `https://impact-1, https://impact-2`.
   - **User ID**: Enter the user ID for the IBM Tivoli Netcool/Impact administrator (example: impactadmin) for connecting to the IBM Tivoli Netcool/Impact endpoint.
   - **Password**: Enter the password for the IBM Tivoli Netcool/Impact administrator for connecting to the IBM Tivoli Netcool/Impact endpoint.
   - **Impact Certificates**: Enter the valid set of CA certificates for IBM Tivoli Netcool/Impact to use for verifying the SSL/TLS connection to the REST services for IBM Tivoli Netcool/Impact.
   - **Deployment options**: This is where the integration connector is deployed, not the location of IBM Tivoli Netcool/Impact. Select one of the options, **Local** or **Remote**. **Local** deploys the integration in the same cluster and project (namespace) where IBM Cloud Pak for AIOps is installed. Alternatively, **Remote** deploys the integration in your chosen location, such as a different network region, on SaaS, or a remote on-premises VM, cluster, or container.
7. Click **Done**.
8. If you selected **Remote**, you are presented with an *Install Cloud Pak for AIOps remote integration* window.
   1. Click **Download shell script** and copy the bootstrap script to a remote VM.

      The bootstrap script requires Podman to run. You can either run it as root or non-root.

      Note: To run Podman as non-root, see the Podman installation.
   2. Run the bootstrap script on the remote VM to complete the deployment.
9. You are redirected to the *IBM Tivoli Netcool/Impact* page for the integration.

   Your new integration is listed in the table on the page. The integration has an intial status of *Initializing*. After a few minutes, the status changes to *Running* if your integration is successful. With your integration successful and running, you now need to configure the integration in IBM Tivoli Netcool/Impact.
10. Configure the integration in IBM Tivoli Netcool/Impact.

To complete the integration, you need to edit the RESTful DSA data source in IBM Tivoli Netcool/Impact.

Editing an IBM Tivoli Netcool/Impact integration

After you create your integration, you can edit the integration. For example, if you want to add or change the listed GUI or backend URLs for the Impact endpoint, or to update the User ID or password. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Tivoli Netcool/Impact** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *IBM Tivoli Netcool/Impact* page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited.

Deleting an IBM Tivoli Netcool/Impact integration

If you no longer need your integration and want to delete it entirely, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.

3. Click the **IBM Tivoli Netcool/Impact** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *IBM Tivoli Netcool/Impact* integrations page, click the *Delete* icon for the integration that you want to delete.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

   Your integration is deleted in IBM Cloud Pak for AIOps. To fully remove the integration, log into the IBM Tivoli Netcool/Impact GUI and delete the IBM Cloud Pak for AIOps data source and policies from IBM Tivoli Netcool/Impact.

Enriching an incident by using IBM Tivoli Netcool/Impact policy

Cloud Pak for AIOps ingests data from many sources and is a central source of truth for a site reliability engineer (SRE) to manage all their disparate systems. You might need to automatically enrich Cloud Pak for AIOps incidents with data from external systems, such as state, ticket number or priority. The additional data gives more insight for an SRE to manage and resolve an incident.

To enrich incidents with data from external systems, use the following steps:

1. Create IBM Tivoli Netcool/Impact policy, which uses the Cloud Pak for AIOps API to enrich the incidents.
2. Create Cloud Pak for AIOps policy to send new incidents to IBM Tivoli Netcool/Impact and invoke the IBM Tivoli Netcool/Impact policy.

Create an IBM Tivoli Netcool/Impact policy to enrich the incidents

From IBM Tivoli Netcool/Impact console, create a JavaScript policy. The code is provided in the following example:

```
Log(
  'Enriching Incident(' + EventContainer.incident.id +
  ') with ticket number from external ITSM system'
);

// This is the DSA created when you create the Netcool/Impact integration with AIOps
var dsa = 'AIOps-jaunpuri1-f243ea05-c344-4d51-9e47-ec7e5031dfea';

// The experimental API being utilised
var AIOPS_INCIDENT_PATH = 'api/issue-resolution/v1alpha1/incidents/';

// The incoming Incident ID from AIOps
var incidentId = EventContainer.incident.id;
var path = AIOPS_INCIDENT_PATH + incidentId;

// In practice this would be a function call to get the URL from the external ITSM system
var ticketLink='https://github.com/oneill/myproject/issues/1489';

// Like ticketLink, this would be a function call. Hardcoded here to simplify
var ticketNumber = '1489';

// Like ticketLink. Hardcoded here to simplify.
var priority = 2;

var incidentUpdateRequest = {
  priority: priority,
  insights: [
    {
      id: String(JavaCall('java.util.UUID', null, 'randomUUID', [])),
      type: 'aiops.ibm.com/insight-type/itsm/metadata',
      source: 'myGithubProject',
      details: {
        id: String(JavaCall('java.util.UUID', null, 'randomUUID', [])),
        name: 'Github',
        type: 'aiops.ibm.com/insight-type/metadata',
        permalink: ticketLink,
        ticket_num: ticketNumber
      }
    }
  ]
};

// Call the experimental API to enrich the AIOps incident
result = RESTfulAPIPATCH(dsa, path, {
  Data: JSON.stringify(incidentUpdateRequest)
});

Log('Enrich Result: ' + result);
if (result.status > 202) {
  throw new Error(
    'Error ' + result.status + ' patching incident ' + id + '\n' +
    result.statusText
  );
}
```

Note: A few values in the preceding code are hardcoded. In actual implementation, your business logic needs to be coded to generate an external ticket, then retrieving the URL and ticket number from an external system. These details can then be effectively incorporated into your policy.

Create Cloud Pak for AIOps policy

Create Cloud Pak for AIOps policy to invoke your IBM Tivoli Netcool/Impact when new incidents are created in Cloud Pak for AIOps.

Policy triggers and policy actions within Cloud Pak for AIOps can resemble the following examples:

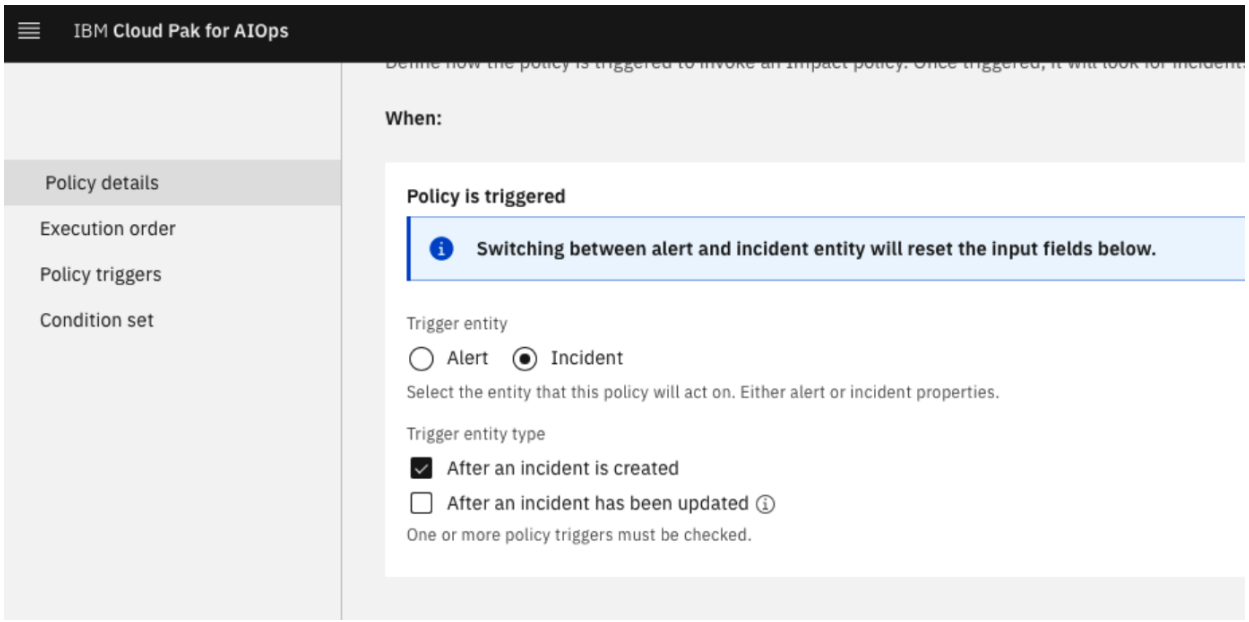

Figure. Policy triggers

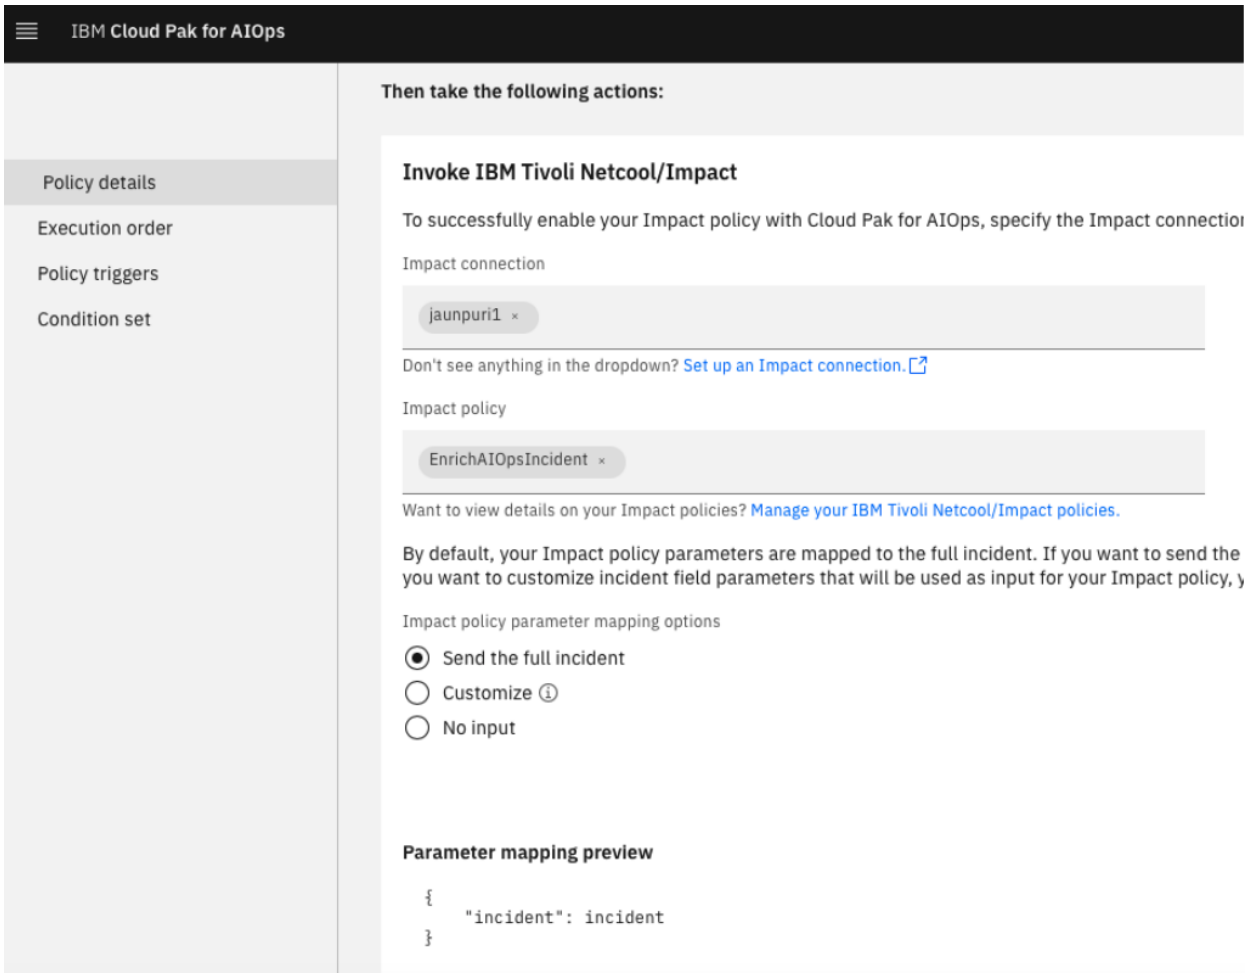

Figure. Policy actions

When new incidents are created in Cloud Pak for AIOps, the incidents automatically invoke your IBM Tivoli Netcool/Impact policy and the incident is updated with the ticket number and any other edits you decided to make to state, priority, or owner.

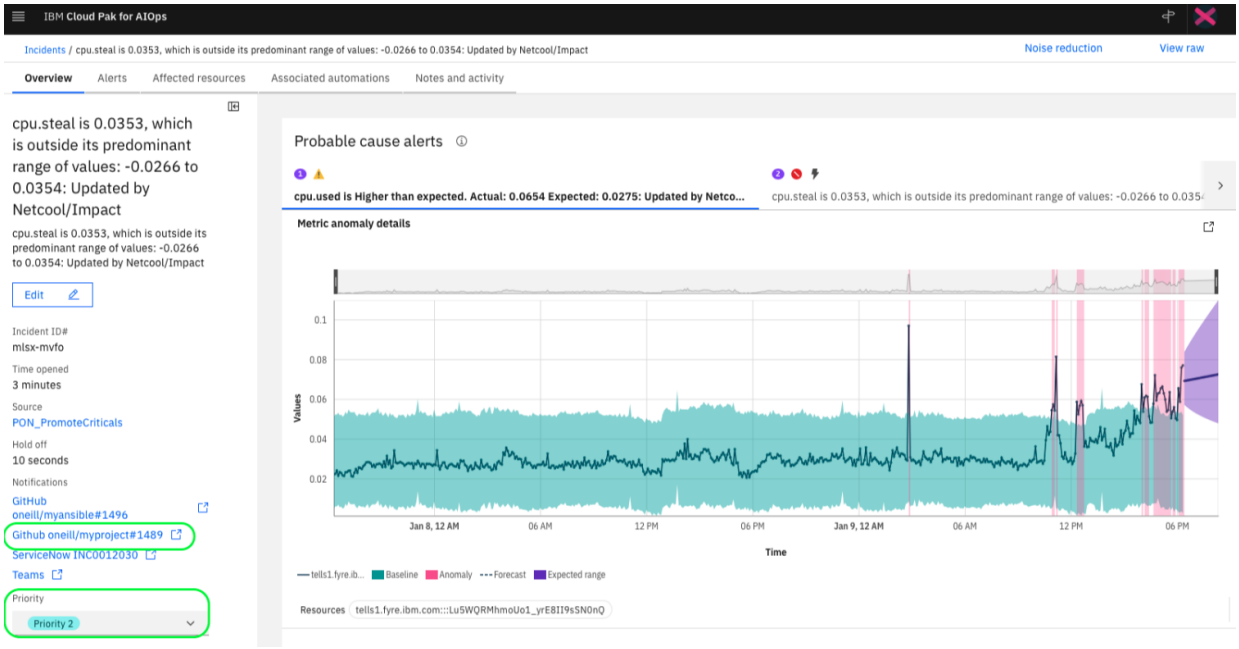

Figure. Incident overview

Note: You can also create further Cloud Pak for AIOps policies to invoke extra IBM Tivoli Netcool/Impact policies when edits are made to the incidents in Cloud Pak for AIOps. For example, if you change the priority or state in Cloud Pak for AIOps and want to write that back to the external ticketing system. For this scenario, in the **Trigger entity type** field in the **Policy details** tab, select **After an incident has been updated**.

Additional information

You can use the following IBM Tivoli Netcool/Impact code snippet to pull out all the ITSM metadata from an incoming Cloud Pak for AIOps incident. This code might be useful to you for further processing in IBM Tivoli Netcool/Impact.

```
var insights = EventContainer.incident.insights;

for (var i = 0; i < insights.length; i++) {
  var thisInsight = insights[i];

  if (thisInsight.type === 'aiops.ibm.com/insight-type/itsm/metadata') {
    Log("Insight: "+thisInsight.details.ticket_num);
  }
}
```

Configuring an integration in IBM Tivoli Netcool/Impact for IBM Cloud Pak for AIOps

Edit the RESTful DSA data source in IBM Tivoli Netcool/Impact for an integration to IBM Cloud Pak for AIOps to finish configuring the integration and integration between IBM Tivoli Netcool/Impact and IBM Cloud Pak for AIOps.

- Before you begin
- Configuring IBM Tivoli Netcool/Impact RESTful DSA data source
- Verifying the integration

Before you begin

1. Ensure that you have created the IBM Tivoli Netcool/Impact integration in the IBM Cloud Pak for AIOps UI. The integration can be created from the Integrations page in the UI. For more information, see Creating IBM Tivoli Netcool/Impact integrations.
2. Obtain the following details for your IBM Cloud Pak for AIOps deployment:
   - Your IBM Cloud Pak for AIOps hostname (cluster_address). For more information about obtaining this information, see Accessing your cluster by using the console.
   - Your encoded (base64 format) Platform UI API Key (**ZenApiKey**) for accessing IBM Cloud Pak for AIOps APIs. If you do not have an existing API key and need to generate a new API key, complete the following steps:

     Accessing APIs - Get authentication by using Platform UI API Key

     You can verify that your API key works by running the following command:

     ```
     curl -kv -H "Authorization: ZenApiKey ${ZenApiKey}" -H "x-tenant-id: ${tenant_id}"
      "https://${CPD_ROUTE}/aiops/api/issue-resolution/v1/alerts/"
     ```

Important: If you lose your API key, repeat the preceding steps to generate a new API key. Your old API key becomes invalid, and any applications or scripts cannot authenticate to the platform until you provide your new API key. For more information, see Accessing APIs.

- The Red Hat OpenShift Container Platform certificate for IBM Cloud Pak for AIOps.

Note: When you create an IBM Tivoli Netcool/Impact integration, the integration creates a Data Source name (DSA) in the IBM Tivoli Netcool/Impact Data Model (as before). The DSA name is created in the format of ***`AIOPs-ConnectorName-ConnectorID`***. Any IBM Tivoli Netcool/Impact policies will now use the new DSA instead of the old one. Therefore, you must update the new DSA with your cluster **Host Name** and **Authorization** (see step 4 below).

Configuring the RESTful DSA data source

1. Open the IBM Tivoli Netcool/Impact GUI.
2. Click and view the **Policies** tab.

   If the integration in IBM Cloud Pak for AIOps is successful, a RESTful DSA data source is already created. In addition, the following default policies are already created.

   - **`AIOPS_HandleAction`** - This file defines the wrapper that is used when IBM Cloud Pak for AIOps invokes an action in IBM Tivoli Netcool/Impact.
   - **`AIOPS_Mappings`** - This file defines how events are sent, and mapped, to IBM Cloud Pak for AIOps.
   - **`AIOPS_Utils`** - This file lists the APIs that are used for communicating with IBM Cloud Pak for AIOps.

   Ensure that these policies exist before proceeding. If they are missing, re-create the integration in IBM Cloud Pak for AIOps.
3. Click the **Data Model** tab.

   An **`AIOps-<identifier>`** RESTful DSA data source is now listed. Click this data source to view the Restful API Data Source Editor for the data model.
4. Go to the **Source** section and update the **Host Name** field with the name of the CPD route value.
5. Update the Request Header authorization setting.
   1. Go to the **Protected Request Headers** section.
   2. Select the **Authorization** header and click **Edit** in the table header.
   3. Update the **Header Value** field to include your encoded Platform UI API Key (**`ZenApiKey`**). This value must be in the following format:

      ```
      ZenApiKey <ZenApiKey>
      ```

      Where **`<ZenApiKey>`** is your encoded Platform UI API Key.
   4. Click **OK**.
6. Import the Red Hat OpenShift Container Platform certificate for IBM Cloud Pak for AIOps.

   To get the certficate, use the following steps:
   1. Export certificate from the IBM Cloud Pak for AIOps API Host:

      ```
      openssl s_client -showcerts -servername <cpd_route_name> -connect <cpd_route_name>:443 </dev/null
      ```

      Note: There are two similar routes, **`cp`** and **`cpd`**. You must use the **`cpd`** route.

      This returns the certificate in the display. The certificate has the following format:

      ```
      -----BEGIN CERTIFICATE-----
      ABCDEfGHIjklMnOPQrSTUVWXYZABCdefghiJ1k2LMNoPQRSTUVwxYZABCDEFGhij
      ... certificate text...
      ... Server 1 ...
      r+wGXNPwrw==
      -----END CERTIFICATE-----
      ```
   2. Copy the text into a certificate file. Then, import the file to the IBM Tivoli Netcool/Impact server and the IBM Tivoli Netcool/Impact UI:

      ```
      $IMPACT_HOME/sdk/bin/keytool -import -v -keystore
      $IMPACT_HOME/wlp/usr/servers/ImpactUI/resources/security/trust.jks -storepass  <impactadmin password> -alias
      aiops -file  <exported_aiops_certificate>
      $IMPACT_HOME/sdk/bin/keytool -import -v -keystore $IMPACT_HOME/wlp/usr/servers/<NCI
      NAME>/resources/security/trust.jks -storepass  <impactadmin password> -alias aiops -file
      <exported_aiops_certificate>
      ```
7. Click the **Save** icon to save your RESTful DSA data source configuration. Then, test your integration.

Verifying the integration

1. Create a test event policy in IBM Tivoli Netcool/Impact to create an alert in IBM Cloud Pak for AIOps.

   Your IBM Tivoli Netcool/Impact policies must be written in JavaScript to work with IBM Cloud Pak for AIOps. The Impact Policy Language (IPL) is not supported through the integration.

   You can use the following example JavaScript structure to help you create your own test policy. Replace the variables **`<variable>`** with the values for your own test event and system details.

```
Load('AIOPS_Utils');
var occurrenceTime = new Date();
var myEventInstance = "<instance_name>";
var event = {
    deduplicationKey: myEventInstance + " <event_name>",
    sender: {
      service: "<service>",
      name: "<sender_name>",
      type: "Success",
      location: "<location>",
      cluster: "\"quotes\"",
      controller: "<script>alert(\"<sender_controller>\");</script>"
    },
    resource: {
      name: myEventInstance + "<resource_name>",
      type: myEventInstance + " <type>",
      service: myEventInstance + " <service>",
      location: "<location>",
      controller: "<resource_controller>",
      interface: "<interface>",
      ipAddress: "<ip_address>",
      hostname: "<hostname>",
      cluster: "<cluster>"
    },
    type: {
      classification: myEventInstance + " <classification>",
      eventType: "<event_type>"
    },
    severity: 6,
    summary: myEventInstance + " <summary>",
    occurrenceTime: occurrenceTime.toISOString()
  };
var res = aiopsUtils.postEventDSA( "AIOps-<UUID>" , event );
Log("res: " + res);
```

Where **<event_type>** can be set to **problem** or **resolution**.

To obtain the **UUID** value to use for the **aiopsUtils.postEventDSA("AIOps-<UUID>" , event)** setting, run the following command:

```
oc get connectorconfiguration -o json | jq -r '.items[] | (.metadata.name + " - " + .metadata.uid)'
```

Note: You need **jq** to run this command. To install **jq**, see Download jq.

Output:

```
impact-netcool - 123abcd4-1ab2-1a23-1a2b-1aabbc234de5
```

The value **123abcd4-1ab2-1a23-1a2b-1aabbc234de5** is the UUID value.

2. Run the policy to test the integration from the IBM Tivoli Netcool/Impact UI **Policies** tab.

   Open the test policy that you created, and click the **Run** icon in the toolbar. Wait a few minutes, then proceeed to the next step.

3. Open the IBM Cloud Pak for AIOps UI and from the main navigation click **Incidents and alerts**. Click the **Alerts** tab to open the Alert Viewer.

   The alert for your test event should now display.

What to do next

- Create policies in IBM Tivoli Netcool/Impact. For more information about setting up these policies, see the IBM Tivoli Netcool/Impact documentation.
- Create a policy in IBM Cloud Pak for AIOps and invoke an IBM Tivoli Netcool/Impact policy. For more information, see:
  - Creating policies
  - Invoke an Impact policy

Creating IBM Netcool Operations Insight ObjectServer integrations

You can send event data from an existing IBM Tivoli Netcool/OMNIbus environment to IBM Cloud Pak for AIOps through an IBM Netcool Operations Insight ObjectServer integration. This integration connects the IBM Tivoli Netcool/OMNIbus ObjectServer with IBM Cloud Pak for AIOps.

With this integration, you can complete the following tasks:

- You can see IBM Tivoli Netcool/OMNIbus event data in the Alert Viewer in IBM Cloud Pak for AIOps. Events are converted into alerts on the IBM Cloud Pak for AIOps side.
- You can take advantage of the IBM Cloud Pak for AIOps AI features. For example, your event data is correlated into incidents, and you can associate topology with your data. You can also create runbooks to automate operations based on your data.

For more information about working with IBM Netcool Operations Insight ObjectServer integrations, see the following sections:

- About IBM Netcool Operations Insight ObjectServer integrations
- Before you begin
- Creating integrations

- Editing integrations
- Deleting integrations

About IBM Netcool Operations Insight ObjectServer integrations

- Though an IBM Netcool Operations Insight ObjectServer integration is bidirectional, not all data is synchronized. For example, if you close an alert in IBM Cloud Pak for AIOps, the alert does not get closed on the IBM Tivoli Netcool/OMNIbus ObjectServer. The **`AIOpsState`** column in the ObjectServer gets updated to closed but the alert continues to stay open on the ObjectServer. The operator must write a trigger on the ObjectServer to close such alerts. However, if an alert is closed on the ObjectServer, the alert does get closed in IBM Cloud Pak for AIOps.
- If you plan to create multiple IBM Netcool Operations Insight ObjectServer integrations, the set of events from each integration must be unique and not overlap with other integrations. For example, if you want to retrieve two separate sets of events, such as odd and even ServerSerial events, then you must use two different integrations. The connection filter helps to group events that you want to synchronize. For more information about the filter, see Filter clause.
    - If you have multiple ObjectServer pairs, you must create a corresponding IBM Netcool Operations Insight ObjectServer integration for each pair. Each ObjectServer pair requires a separate IBM Netcool Operations Insight ObjectServer integration. Do not reconfigure an existing IBM Netcool Operations Insight ObjectServer integration to access another ObjectServer pair.

      Note: An ObjectServer pair must synchronize with only one IBM Cloud Pak for AIOps instance through one or more IBM Netcool Operations Insight ObjectServer integrations. If you want to repoint an ObjectServer pair to a different IBM Cloud Pak for AIOps instance, clear the **`AIOpsAlertID`** and **`AIOpsState`** columns in the **`alerts.status`** table on the ObjectServer before you start the new deployment.
    - Parallel IBM Netcool Operations Insight ObjectServer integrations can be useful for distributing event load. However, use such a deployment only if necessary.

Before you begin

To configure an IBM Netcool Operations Insight ObjectServer integration, you need the following information:

- ObjectServer credentials
- Hostname and port for the primary and backup ObjectServers
- Custom ObjectServer column mapping

Creating IBM Netcool Operations Insight ObjectServer integrations

To create an IBM Netcool Operations Insight ObjectServer integration for IBM Tivoli Netcool/OMNIbus, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **IBM Netcool Operations Insight ObjectServer** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. To configure the ObjectServers with IBM Cloud Pak for AIOps columns, complete the following steps under *Configure ObjectServer*:
    - Open a command line.
    - Connect to the Netcool ObjectServer Host.
    - Save the following SQL commands in a file called *add_trigger.sql*:

```
-- Add IBM Cloud Pak for AIOps required fields ---
alter table alerts.status add column AIOpsAlertId varchar(64);
go

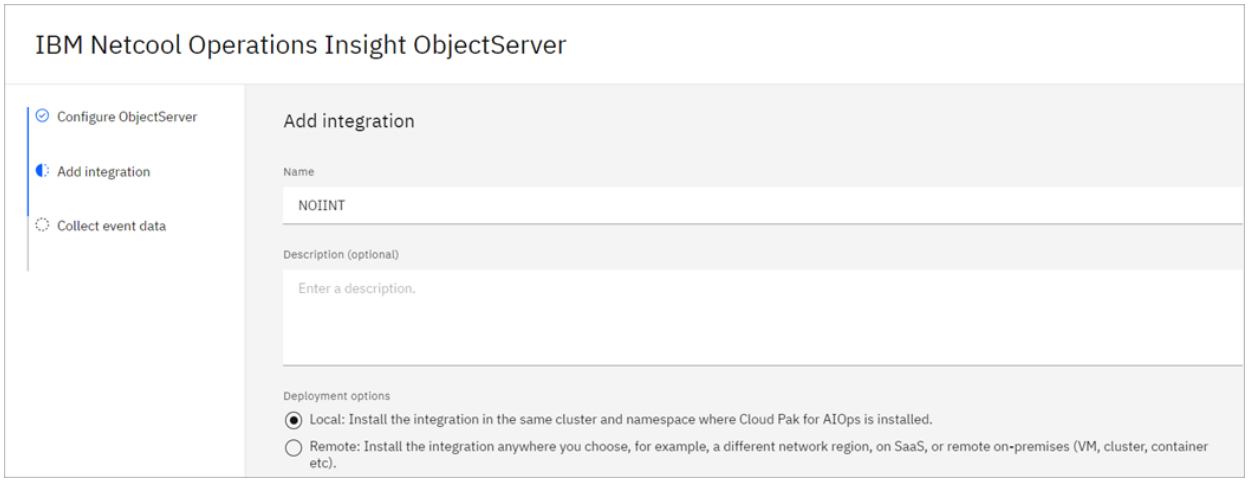
alter table alerts.status add column AIOpsState varchar(16);
go

-- Add the Netcool integration automation trigger group --
create or replace trigger group NetcoolConnectorAutomation;
go

-- Enable the trigger --
alter trigger group NetcoolConnectorAutomation set enabled true;
go

-- Add the clear automation trigger --
create or replace trigger netcool_connector_clear_alerts
group NetcoolConnectorAutomation
priority 1
comment 'Netcool integration clear alerts that are closed in IBM Cloud Pak for AIOps.'
every 10 seconds
when get_prop_value('ActingPrimary')%='TRUE'
begin
   -- Set Sev to 0  if AIOpsState is closed
```

```
   for each row problem in alerts.status where
       problem.Type = 1 and problem.Severity > 0 and problem.AIOpsAlertId != '' and problem.AIOpsState =
'closed'
   begin
       update alerts.status via problem.Identifier set Severity = 0;
   end;
end;
go
```



Note: The ScopeID column is available by default on Red Hat OpenShift Container Platform. However, use the following command for setting it up for on-premises ObjectServer:

```
alter table alerts.status add column ScopeID varchar(255);
go
```

- Run the following command to install the required columns and trigger by using the *add_trigger.sql* file:

```
$OMNIHOME/bin/nco_sql -server <object_server_name> -username root -password <password> < add_trigger.sql
```

7. Click **Next**.
8. Enter the following *Add integrations* information:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **Deployment options**: Select **Local** or **Remote** option.

   Note: If you select local, the deployment is in the same cluster where IBM Cloud Pak for AIOps is installed. If you select remote, the deployment happens wherever you choose, for example, on a different network region, on Saas, or remotely on premises (VM, cluster, or container).

9. Fill the *ObjectServer pair* fields. For more information about the fields and values to be entered, see Table 1.
10. Click **Test Connection**. If successful, a *Test succeeded* message is displayed. If it fails, one of the following reasons appears:

- Filter is not valid
- Unable to connect to ObjectServer
- IBM Cloud Pak for AIOps fields not present

Note: If the test fails, check:

- if the *TLS certificate* is correct.
- if the *NetworkPolicy* is created with the correct ports and in the correct namespace.
- if the *ExternalName* service is created with correct service name, ports, and in the correct namespace.

For more information about *TLS certificate*, *NetworkPolicy*, and *ExternalName* service, see TLS-enabled connection.

11. Click **Next**.
12. Enter the following *Collect event data* information to define how active IBM Tivoli Netcool/OMNIbus events are collected.
    - **Enable data collection**: This toggle is set to *on* by default. It starts to collect event data from IBM Tivoli Netcool/OMNIbus immediately on creation of the integration.

- **Mapping**: This field provides mapping for standard IBM Tivoli Netcool/OMNIbus event columns that use Jsonata syntax. You can add your own custom ObjectServer columns to this mapping. If they have custom alert columns in your ObjectServer, you must add them to the Jsonata mapping provided in the Mapping textbox.

  Note: To customizing the mapping, copy the text out of the mapping textbox and into your preferred text editor. Then, add the mapping for those custom columns there and check the code syntax. When done, copy the Jsonata code back into the mapping textbox. If successful, a *Valid Jsonata configuration* message is displayed. Be aware that Jsonata is case sensitive. For details about Jsonata syntax and usage see JSONata Documentation.

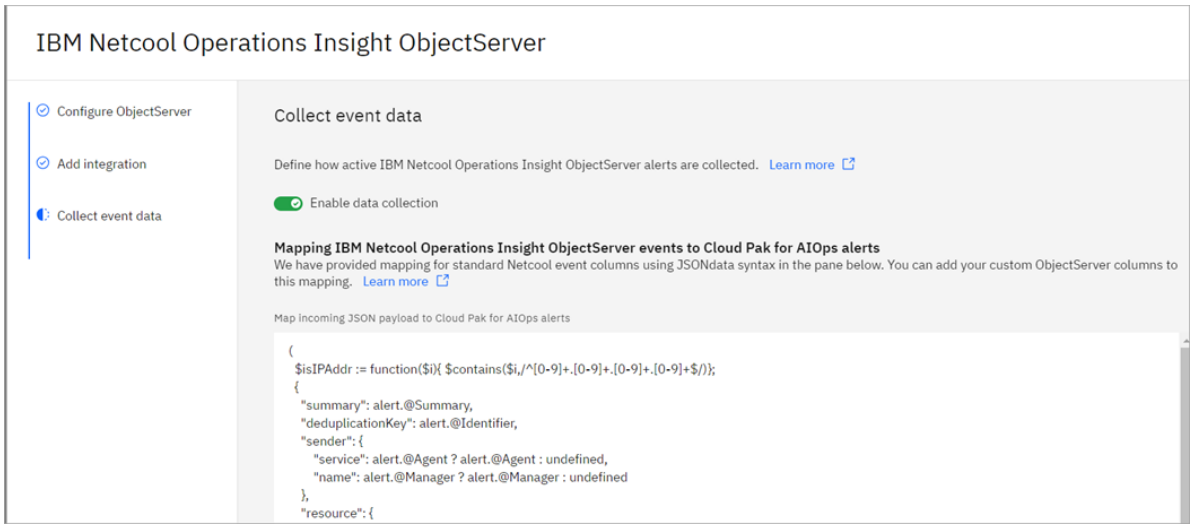


Figure. Collect event data

13. Click **Save**.

You have created an IBM Netcool Operations Insight ObjectServer integration in your instance, and a message appears on the integrations page that states *Connection completed. IBM Cloud Pak for AIOps has successfully processed your request*.

After you integrate with IBM Tivoli Netcool/OMNIbus, use IBM Cloud Pak for AIOps and the IBM Cloud Pak for AIOps UI for AI and visualization features. Use IBM Tivoli Netcool/OMNIbus and the associated UI tools for obtaining and sending data to IBM Cloud Pak for AIOps.

Notes:

- If you are integrated and are not yet ready, or able, to move to using IBM Cloud Pak for AIOps and the IBM Cloud Pak for AIOps UI fully. You can continue to use the IBM Tivoli Netcool/OMNIbus DASH custom dashboards and Web GUI event viewer as you transition to IBM Cloud Pak for AIOps. If you need to continue to use IBM Tivoli Netcool/OMNIbus tools, you can configure launch-in-context links from the Web GUI to the IBM Cloud Pak for AIOps UI to help users access and use IBM Cloud Pak for AIOps UI. For more information, see Configuring launch-in-context from IBM Tivoli Netcool/OMNIbus
- If you plan to connect with an IBM Tivoli Netcool/OMNIbus deployment in an environment that is enabled to support Federal Information Processing Standards (FIPS), you need to configure your integration to also enable the support. For more information, see Enabling support for Federal Information Processing Standards (FIPS).

ObjectServer pairs

The following table outlines the ObjectServer pair fields and their values.

Table 1. ObjectServer pair fields

ObjectServer pair fields	Description	Values
Admin username	Enter a username to authenticate to the ObjectServer.	$ NOI_OMNI_USERNAME
Admin password	Enter a password to authenticate to the ObjectServer.	$ NOI_OMNI_PASSWORD
Filter (optional)	Define the alerts that you want to synchronize by using ObjectServer SQL where clause syntax. Without filter, the integration takes all alerts from the database table.	For example, Severity > 4 or Manager LIKE 'CEM'. For more examples, see Filter clause.
Is TLS enabled?	Enable or disable the toggle button. For more information about TLS-enabled connection, see TLS-enabled connection.	**Yes** or **No**
Primary ObjectServer hostname	Enter a hostname for the primary ObjectServer integration.	$ NOI_PROXY_PRIMARY_SVC
Primary ObjectServer port	Specify a port.	$ NOI_PROXY_PRIMARY_PORT
Backup ObjectServer hostname (Optional)	Enter a hostname for the backup ObjectServer integration.	$ NOI_PROXY_BACKUP_SVC
Backup ObjectServer port (Optional)	Specify a port.	$ NOI_PROXY_BACKUP_PORT
Trusted certificates (if TLS is enabled)	Enter the TLS certificate that is used to verity the SSL/TLS connection to the ObjectServers.	See TLS-enabled connection

TLS-enabled connections

A TLS-enabled connection provides end-to-end security to data that is transmitted through it. To activate a TLS-enabled connection, you must provide a Transport Layer Security (TLS) certificate. A TLS certificate is a type of digital certificate, issued by a certificate authority (CA), verifying the ownership of the domain name.

You can create a TLS-enabled connection to either Red Hat® OpenShift® Container Platform ObjectServer, or the On-premises IBM Tivoli Netcool/OMNIbus ObjectServer. For more information, see:

- Creating a TLS-enabled integration to a Red Hat® OpenShift® Container Platform ObjectServer

Editing IBM Netcool Operations Insight ObjectServer integrations

After you create your integration, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Netcool Operations Insight ObjectServer** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Netcool Operations Insight ObjectServer integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration.

   Note: While you can modify all other fields, you cannot alter the actual integration name at this stage, as it is already created and thus shows as read-only.

6. Click **Save** when you are done editing.

Your integration is edited. If you did not previously enable or disable your application, you can enable or disable the integration directly from the console. For more information about deleting a integration, see Deleting IBM Netcool Operations Insight ObjectServer integrations.

Deleting IBM Netcool Operations Insight ObjectServer integrations

If you no longer need your IBM Netcool Operations Insight ObjectServer integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before deleting your integration.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Netcool Operations Insight ObjectServer** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Netcool Operations Insight ObjectServer integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

If you want to remove columns and automation triggers from Netcool ObjectServer, complete the following steps:

1. Open a terminal.
2. Connect to the Netcool ObjectServer host.
3. Save the following SQL commands into a file called *remove_trigger.sql*:

```
alter trigger group NetcoolConnectorAutomation set enabled false;
go

drop trigger netcool_connector_clear_alerts;
go

drop trigger group NetcoolConnectorAutomation;
go

alter table alerts.status drop column AIOpsAlertId;
go
```

```
alter table alerts.status drop column AIOpsState;
go
```

4. Run the following command to install the required columns and trigger by using the remove_trigger.sql file:

```
$OMNIHOME/bin/nco_sql -server <object_server_name> -username root -password <password> < remove_trigger.sql
```

Configuring launch-in-context from IBM Tivoli Netcool/OMNIbus

If you have integrated IBM Cloud Pak for AIOps and IBM Tivoli Netcool/OMNIbus, you can configure launch-in-context links from the Web GUI Event Viewer and the main DASH navigation to the IBM Cloud Pak for AIOps UI to help your users access and use the IBM Cloud Pak for AIOps UI.

With these links, your users can use the Web GUI Event Viewer and DASH to manage the gathering of event data, which is then sent to IBM Cloud Pak for AIOps. These users can then launch the IBM Cloud Pak for AIOps UI for AI analysis and visualization of the data.

Creating an integration between IBM Cloud Pak for AIOps and IBM Tivoli Netcool/OMNIbus to send event data to Cloud Pak for AIOps is prerequisite. For more information, see Creating IBM Netcool Operations Insight ObjectServer integrations.

For more information about configuring launch-in-context, see:

- Adding incidents and alerts to the DASH navigation menu
- Creating tools for launch-in-context from Netcool/OMNIbus Event Viewer

Adding incidents and alerts to the DASH navigation menu

If you have integrated IBM Cloud Pak for AIOps and IBM Tivoli Netcool/OMNIbus, you can add a launch-in-context link to the IBM Cloud Pak for AIOps Incidents and alerts page to the DASH navigation menu for IBM Tivoli Netcool/OMNIbus.

Procedure

1. Navigate to the JAZZSM_HOME directory and open the following file:
   <JAZZSM_HOME>/profile/config/cells/JazzSMNode01Cell/applications/isc.ear/deployments/isc/isclite.war/WEB-INF/navigation.xml

2. At the end of the content wrapped between the following tags:

   ```
   <navigation:navigation-tree> {...} </navigation:navigation-tree>
   ```

   Append the following XML snippet, replacing the values marked as **<CP4WAIOPS_STORIES_URL>** and **<CP4WAIOPS_ALERTS_URL>** with valid URLs to the Cloud Pak for AIOps Incidents and Alerts pages:

   ```
   <navigation:nav-element formPersistence="false" hidden="false" iconClass="cloudIcon" isWscNode="false"
   layoutUpdatedAtRuntime="false" moduleID="com.ibm.isclite.global.custom.module"
   moduleIDOrig="com.ibm.isclite.global.custom.module" nodeType="label" securityUpdatedAtRuntime="false"
   stateMaintained="false" taskType="hiddenTask" uniqueName="com.ibm.isclite.global.custom.module-SPSVS-
   label.W8DQOK4vA5VBn4RGGldV-u11650881799360" wscRole="all authenticated portal users" wscRoleType="User">
     <navigation:title>
       <base:nls-string lang="en">CP4WAIOps</base:nls-string>
     </navigation:title>
     <navigation:parentTree parentTreeRef="root"/>
     <navigation:parameter name="com.ibm.console.resource.previewImage">
       <base:value>
       <base:string>CP4WAIOps</base:string>
       </base:value>
     </navigation:parameter>
     <navigation:parameter name="com.ibm.console.resource.description">
       <base:value>
       <base:string>CP4WAIOps</base:string>
       </base:value>
     </navigation:parameter>
     <navigation:page-params/>
     <navigation:nav-element formPersistence="false" hidden="false" isWscNode="false" layout-element-
   ref="com.ibm.isclite.admin.Freeform.layoutElement.A__1650882838344" layoutUpdatedAtRuntime="true"
   moduleID="com.ibm.isclite.global.custom.module" moduleIDOrig="com.ibm.isclite.global.custom.module" nodeType="url"
   securityUpdatedAtRuntime="false" stateMaintained="true" taskType="multiTask"
   uniqueName="com.ibm.isclite.global.custom.module-SPSVS-
   com.ibm.isclite.admin.Freeform.navigationElement.pagelayoutA.modified.9L7ci90Q2Z7x3uGKVJ2v5uh1650882838339" url="
   <CP4WAIOPS_STORIES_URL>" wscRole="iscadmins" wscRoleType="Editor">
       <navigation:title>
       <base:nls-string lang="US">Incidents</base:nls-string>
       </navigation:title>
       <navigation:parentTree parentTreeRef="label.W8DQOK4vA5VBn4RGGldV-u11650881799360"/>
     </navigation:nav-element>
     <navigation:nav-element formPersistence="false" hidden="false" isWscNode="false" layout-element-
   ref="com.ibm.isclite.admin.Freeform.layoutElement.A__1651490860014" layoutUpdatedAtRuntime="true"
   moduleID="com.ibm.isclite.global.custom.module" moduleIDOrig="com.ibm.isclite.global.custom.module" nodeType="url"
   securityUpdatedAtRuntime="false" stateMaintained="true" taskType="multiTask"
   uniqueName="com.ibm.isclite.global.custom.module-SPSVS-
   com.ibm.isclite.admin.Freeform.navigationElement.pagelayoutA.modified.taRbaKSlGPLajMfN2BbRVfB1651490860008" url="
   <CP4WAIOPS_ALERTS_URL>" wscRole="iscadmins" wscRoleType="Editor">
       <navigation:title>
   ```

```
    <base:nls-string lang="US">Alerts</base:nls-string>
    </navigation:title>
    <navigation:parentTree parentTreeRef="label.W8DQOK4vA5VBn4RGGldV-u11650881799360"/>
  </navigation:nav-element>
</navigation:nav-element>
```

3. Save the `navigation.xml` file.
4. Log out of DASH, then log back in again.

Creating a tool for launch-in-context from IBM Tivoli Netcool/OMNIbus Event Viewer

To use a launch-in-context tool, you must add it to the list of available IBM Tivoli Netcool/OMNIbus tools by using the **Tool Configuration** option within the IBM Tivoli Netcool/OMNIbus Web GUI. You must then add the tool to the list of tools that appear on the pop-up menu in the IBM Tivoli Netcool/OMNIbus Event Viewer by using the **Menu Configuration** option.

Complete the steps in the following procedure to create the tool for launch-in-context from selected events in the Event Viewer.

Procedure

1. As a user with the admin role, log in to your DASH web application.
2. Open the Netcool/OMNIbus Web UI tool configuration page: **Administration > Event Management Tools > Tool Configuration**.
3. Click the create tool icon to create a new tool.
4. Enter a name for the tool, for example "View in IBM Cloud Pak for AIOps".
5. From the **Type** drop-down field, select **CGI/URL**.
6. Paste the following URL in the field provided:

   ```
   <aiops hostname>:<aiops port>/aiops/cfd95b7e-3bc7-4006-a4a8-a73a79c71255/resolution-hub/alerts?
   selectedRowIds=alerts.status.undefined:{$selected_rows.AIOpsAlertId}&selectedColumnId=summary
   ```

   Where `<aiops hostname>:<aiops port>` is the URL of your IBM Cloud Pak for AIOps instance in the format of protocol://hostname:port.
7. Click **Save**.
8. Open the Netcool/OMNIbus Web UI menu configuration page: **Administration > Event Management Tools > Menu Configuration**.
9. Click the **Alerts** menu and select **Modify**.
10. Locate the tool that you created in the available list and add it to the list of selected tools.
11. Click **Save**.

This tool should now be available in the Event Viewer when you right-click on an Event. Selecting this tool launches into the Cloud Pak for AIOps alerts for the selected event.

Creating a TLS-enabled IBM Netcool Operations Insight ObjectServer integration to an Red Hat OpenShift ObjectServer

If you are connecting IBM Cloud Pak for AIOps to IBM Tivoli Netcool/OMNIbus and you have TLS enabled for your Red Hat OpenShift ObjectServer, you need to extract the TLS certificate to add to IBM Cloud Pak for AIOps.

A TLS-enabled connection between IBM Cloud Pak for AIOps and IBM Tivoli Netcool/OMNIbus provides end-to-end security to data that is transmitted through it. To create a TLS-enabled connection to a Red Hat OpenShift ObjectServer, complete the following steps:

1. Get the host and port for primary and backup ObjectServers from the TLS Proxy service:

   ```
   NOI_INSTANCE=<NOI_instance_name>
   NOI_NAMESPACE=<NOI_namespace>
   NOI_PROXY_SVC=${NOI_INSTANCE}-proxy
   NOI_PROXY_PRIMARY_SVC=${NOI_PROXY_SVC}.${NOI_NAMESPACE}.svc
   NOI_PROXY_PRIMARY_PORT=$(oc describe svc -n $NOI_NAMESPACE $NOI_PROXY_SVC | grep aggp-proxy-port | awk -F' ' '{
   print $3 }' | awk -F'/' '{ print $1 }')
   NOI_PROXY_BACKUP_SVC=${NOI_PROXY_SVC}.${NOI_NAMESPACE}.svc
   NOI_PROXY_BACKUP_PORT=$(oc describe svc -n $NOI_NAMESPACE $NOI_PROXY_SVC | grep aggb-proxy-port | awk -F' ' '{ print
   $3 }' | awk -F'/' '{ print $1 }')
   ```

   Where, `<NOI_instance_name>` is the Netcool instance name that is installed in the cluster and `<NOI_namespace>` is the namespace where Netcool is installed. For example, `NOI_NAMESPACE=noi`.
2. Create a *NetworkPolicy* in the Netcool namespace to allow the probe to access the TLS Proxy service and port in the IBM Netcool Operations Insight namespace. To create the *NetworkPolicy*, complete the following steps:

1. Set the environment variables.

```
NOI_INSTANCE=<NOI_instance_name>
NOI_NAMESPACE=<NOI_namespace>
NOI_OBJSERV_AGG_PRIMARY_SVC=$NOI_INSTANCE-objserv-agg-primary
NOI_OBJSERV_AGG_BACKUP_SVC=$NOI_INSTANCE-objserv-agg-backup
NOI_OBJSERV_AGG_PRIMARY_PORT=$(kubectl get svc -n $NOI_NAMESPACE $NOI_OBJSERV_AGG_PRIMARY_SVC -o
jsonpath='{.spec.ports[?(@.name=="primary-tds-port")].port}')
NOI_OBJSERV_AGG_IDUC_PORT=$(kubectl get svc -n $NOI_NAMESPACE $NOI_OBJSERV_AGG_PRIMARY_SVC -o
jsonpath='{.spec.ports[?(@.name=="primary-iduc-port")].port}')
```

   Where **<NOI_instance_name>** is the Netcool instance name that is installed in the cluster and **<NOI_namespace>** is the namespace where Netcool is installed.

2. Run the following commands:

```
cat << EOF | tee >(oc apply -f -) | cat
kind: NetworkPolicy
apiVersion: networking.k8s.io/v1
metadata:
   name: noi-allow-objectserver
   namespace: ${NOI_NAMESPACE}
spec:
   podSelector:
      matchLabels:
         app.kubernetes.io/instance: ${NOI_INSTANCE}
         appClass: objserv
   ingress:
      - ports:
         - protocol: TCP
           port: ${NOI_OBJSERV_AGG_PRIMARY_PORT}
         - protocol: TCP
           port: ${NOI_OBJSERV_AGG_IDUC_PORT}
   policyTypes:
      - Ingress
EOF
```

   Note: Check to see whether the existing *NetworkPolicy* allows the probe to access the TLS Proxy service and port in Netcool namespace. The *NetworkPolicy* must show both the primary and IDUC ports.

3. Create an *ExternalName* service for the primary and IDUC ports. It maps the namespace scoped service to the Netcool service in the namespace. To create the *ExternalName* service, complete the following steps:

   1. Set the environment variables.

```
AIMANAGER_NAMESPACE=<AIManager_namespace>
oc project $AIMANAGER_NAMESPACE
```

      Where **<AIManager_namespace>** is the namespace where IBM Cloud Pak for AIOps is installed.

   2. Run the following commands.

```
cat << EOF | tee >(oc apply -f -) | cat
apiVersion: networking.k8s.io/v1
kind: Service
apiVersion: v1
metadata:
  name: ${NOI_INSTANCE}-objserv-agg-primary
  namespace: ${AIMANAGER_NAMESPACE}
spec:
  type: ExternalName
  externalName: ${NOI_INSTANCE}-objserv-agg-primary.${NOI_NAMESPACE}.svc.cluster.local
  ports:
  - port: 4101
    name: primary-iduc-port
---
kind: Service
apiVersion: v1
metadata:
  name: ${NOI_INSTANCE}-objserv-agg-backup
  namespace: ${AIMANAGER_NAMESPACE}
spec:
  type: ExternalName
  externalName: ${NOI_INSTANCE}-objserv-agg-backup.${NOI_NAMESPACE}.svc.cluster.local
  ports:
  - port: 4101
    name: backup-iduc-port
---
EOF
```

4. Obtain a TLS certificate. To obtain the TLS certificate for the ObjectServer, run the following command:

```
oc extract secret/$NOI_INSTANCE-proxy-tls-secret -n $NOI_NAMESPACE   --to=. --keys=tls.crt
```

Filter clauses for an IBM Netcool Operations Insight ObjectServer integration

For an integration between IBM Cloud Pak for AIOps and IBM Tivoli Netcool/OMNIbus, you can use the filter clause to define the alerts that you want to send to IBM Cloud Pak for AIOps. You can create filter clauses that are suitable for your environment by using an ObjectServer SQL **where** clause syntax.

To generate filter clauses, use fields from the ObjectServer **alerts.status** table, such as **ServerName**, **Agent**, or **Manager** for the syntax. The following example shows this syntax:

```
ServerName IN ('Server1','Server2')
```

Filter clause examples

The following table outlines some of the examples of **FILTER** clause and their description:

Filter clause examples

Filter examples	Description
`Agent != 'OMNIbus SelfMonitoring'`	This filter clause filters all events in the ObjectServer **alerts.status** table with the **Agent** field not equal to **OMNIbus SelfMonitoring**.
`Manager not like 'OMNIbus Self Monitoring*'`	This filter clause filters all events in the ObjectServer **alerts.status** table with the **Manager** field not starting with **OMNIbus Self Monitoring**. For more examples of **Manager** field, see Note.
`Severity >= 2`	This filter clause filters all events in the ObjectServer **alerts.status** table with **Severity** field equal to or beyond the warning level. Thus, the integration selects only those alerts that have severity more than or equal to 2. For more information about severity level representation, see Event severity levels.
`ServerName IN ('AGG_P','AGG_B')`	This filter clause filters all events in the ObjectServer **alerts.status** table with ServerName equal to **AGG_P** and **AGG_B**. Thus, the integration selects only those alerts that originate from **'AGG_P'** and **'AGG_B'**.

The following are some examples of the **Manager** field:

```
OMNIbus Self Monitoring @AGG_P
OMNIbus Self Monitoring @AGG_B
```

Where **AGG_P** and **AGG_B** are server names.

You can use Boolean operators such as **AND, OR** to join conditions in the filter clause syntax. For example,

```
Acknowledged>0 AND ServerName IN ('NCOMS_US','NCOMS_CA')
```

Netcool event load management

The event rate that the ObjectServer can handle is greater than a Netcool connector can handle. As a consequence, you may need to run more than one Netcool connector instance and distribute the event load amongst the them.

The need to distribute the event load arises when the Netcool connectors deployed are showing signs of the SAF file count growing constantly. This indicates that Netcool event load is breaching the connector's processing limit. Unmitigated piling of SAF files will cause issues in the pod's file system and the database for Netcool data files encompassing cache file, outbound SAF, and inbound SAF. This can cause an event delay or missing events in IBM Cloud Pak for AIOps.

To prevent storage issues, high event load must be distributed across multiple connectors.

The best practice is to split the event load and enable each connector's IDUC query on alternate alert rows to achieve evenness in event sourcing. In the Netcool connector UI configuration, append the following clause to the filter definition.

```
(mod(ServerSerial,X)=Y)
```

Where **X** is the total number of connectors deployed and **Y** is the index for each connector.

For example, if there are five connectors to be used, X=5 and Y ranges from 0 to 4:

```
connector_1: FILTER AND (mod(ServerSerial,5)=0)
connector_2: FILTER AND (mod(ServerSerial,5)=1)
connector_3: FILTER AND (mod(ServerSerial,5)=2)
connector_4: FILTER AND (mod(ServerSerial,5)=3)
connector_5: FILTER AND (mod(ServerSerial,5)=4)
```

Important: The filter definition must be same across this group of connectors.

Measuring event load and SAF file growth manageable by one connector

A connector's IDUC occurs every 30 seconds to fetch Netcool events from ObjectServer. In one IDUC cycle the number of SAF files generated is proportional to the events fetched. Each SAF file can buffer up to 1000 entries of events. The connector's SAF processor consumes SAF files for event data mapping and forwarding. SAF processor can complete processing two 100%-filled SAF files in a minute. Complexity of custom mapping rules and Kafka endpoint performance will be to some degree lengthning the processing time to get every event mapped and forwarded, but this SAF per minute baseline should serve as a guideline for planning the number of connectors to be deployed.

Clean up for a fresh start

You must clean up is mandatory on Netcool connector and AIOps when there are changes in any of the following items:

- Number of Netcool connector instances
- Filter definition

For details of cleaning up the deployment see the steps for resynchronizing the alerts from Netcool and AIOps described in this procedure

Netcool connector troubleshooting

If you experience any problems when creating a Netcool connector, use the following troubleshooting steps:

1. When you create the connector instance, ensure data flow is enabled and that the following fields are added on the ObjectServer: **`AIOpsAlert ID`**, **`AIOpsAlertState`**, and **`ScopeID`**.
2. If you are unable to get a successful test connection from the IBM Cloud Pak for AIOps UI, use the following stpes:
    1. Check you have a valid entry for the connector in the ObjectServer **`omni.dat`** file.
    2. Ensure the port is not already in use.
    3. Check whether there are any firewall rules that maybe blocking the connection.
3. On successful creation of a Netcool connector, you should see the following objects created on the OpenShift Console:
    - Netcool-conn-pod
    - Netcool PVC (Check that the PVC size default is set to 2Gi.)
4. Check the connector bridge pods.
    - If you notice connector bridge pods restarting many times, or they are down, check the connector bridge pod logs for exceptions:

      ```
      oc logs <connector-bridge-xxx>
      ```

    - If you see the following message in the connector bridge pods:

      ```
      containerStatuses:
          lastState:
            terminated:
              exitCode: 137
              finishedAt: "2024-06-07T02:48:52Z"
              reason: OOMKilled
      ```

    This is an indication that the load incoming into the system is higher than the connector bridge can manage. The connector fails with the message: **`out of memory: OOMKilled`**
5. If events are not flowing into IBM Cloud Pak for AIOps, ensure the components are running:

    ```
    oc get installation -o yaml
    ```

    This shows all that components that are in Ready state.
    1. Ensure all kafka pods are in running state and not restarting.
    2. Ensure the lifecycle pods are running as expected:

       ```
       cp4waiops-eventprocessor-eve-29ee-ep-jobmanager
       cp4waiops-eventprocessor-eve-29ee-ep-taskmanager
       ```

    3. Ensure the following job is completed:

       ```
       cp4waiops-eventprocessor-eve-29ee-ep-taskmanager
       job.batch/aiops-ir-lifecycle-create-policies-job
       job.batch/aiops-ir-lifecycle-policy-registry-svc-job
       job.batch/aiops-ir-lifecycle-policy-upgrade-job
       job.batch/aiops-ir-lifecycle-sync-es-cassandra-cronjob-28654560
       ```

    4. Ensure all the workloads are running as expected. If any of the workloads are in failure state, you would not see events in IBM Cloud Pak for AIOps.
6. Custom Mapping.
    1. If you still do not see any events coming in, review your mapping in the connector config.
    2. Test with the default mappings to see if events are flowing in.
    3. Ensure that all custom fields (if integers) are type casted to string value.
7. Resync the connector.
    1. At the connector UI, disable the collector's data collection.
    2. In the connector pod, delete all files under /bindings/netcool-connector/omnibus/var/G_CONNECTOR.
    3. At the ObjectServer alerts.status table, reset the AIOpsAlertId and AIOpsState columns.
    4. At AIOps, remove all alerts from the ObjectServer.
    5. At the connector UI, enable the collector's data collection. **Note:** if the columns in the NOI objects server AIOpsAlertId and AIOpsState columns are not reset you may not see events in AIOPS as these mark that the connector has already actioned this events
8. Clearing Events and resetting Lifecycle state. Reset lifecycle state after running the following command on the **`must-gather`** script.

    ```
    waiops-mustgather.sh -DR -C clear-lifecycle-state.sh
    ```

    Note: Clearing the lifecycle state is generally done after recovery of the Issue Resolution Lifecycle operator or clearing events in Cloud Pak for AIOps and resetting lifecycle state.

Netcool event load splitting calculation

When you deploy IBM Netcool Operations Insight ObjectServer integrations, it is important to understand the event rate of domain alerts and calculate the number of integrations that are required to share the overall load. A high event load can lead to breakdowns due to the integration pod's file storage that is filled with unprocessed Store-and-Forward (SAF) files. By planning and sizing your Netcool Operations Insight integrations deployment, you can help ensure that it runs smoothly and efficiently.

IDUC and SAF files

- Netcool Operations Insight integration triggers an IDUC query to ObjectServer for latest alert events every thirty seconds.
- The events that are fetched by IDUC are buffered in SAF files. This activity can be seen as SAG staging.
- When a SAF file passes the staging phase, it is consumed by the integration's data forwarding process.
- Each SAF file can hold up 1,000 entries of Netcool Operations Insight events, but the maximum size of a fully filled SAF file is determined by the table columns that are involved in IDUC.
- The columns of interest for IDUC data replication are configured in the integration's mapping. More columns require more space usage per SAF file, but the file size alone is not the factor of file storage depletion. The unmitigated growth of SAF files is the main cause to the storage issue.
- Multiple SAF files might be produced in one IDUC. These files might be partially filled because the SAF staging process marks the file ready for the SAF processing (data forwarding process) to consume when either of the following conditions is met:
    - The SAF file is fully filled. For example, 1000 rows.
    - The wait time for more rows that are coming in is expired.

Optimal rate of SAF file growth

- To prevent the pile up of SAF files, all the SAF files that are produced in the N-th cycle of IDUC need to be processed by the data forwarding process before the end of the (N+1)-th cycle.
- The data forwarding process is running in parallel to IDUC and SAF staging.
- If there are more than 1,000 changed rows that are detected in an IDUC query, then multiple batching is required to complete the pulling of all the changed rows from the ObjectServer.

Understanding IDUC, SAF staging, and SAF processing

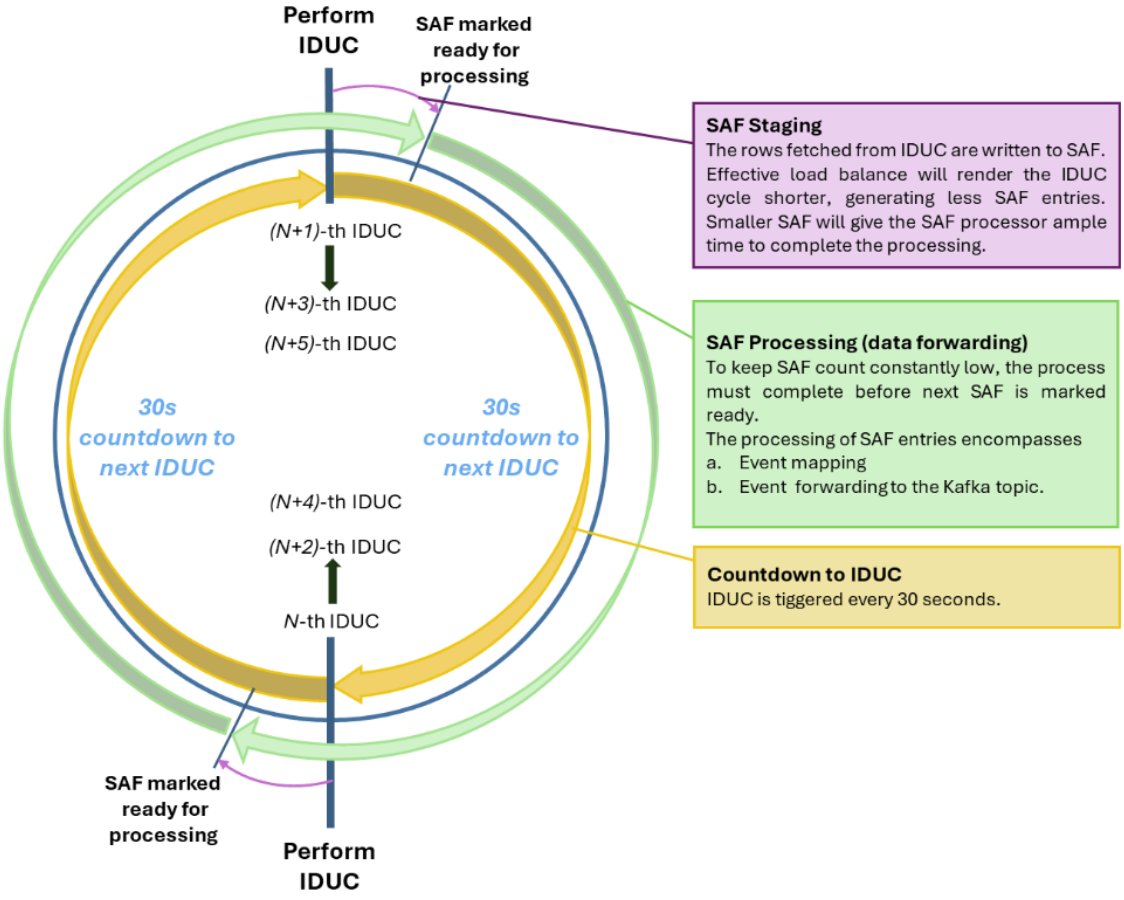

Figure. Cycles of IDUC, SAF staging, and processing projected in clock dial view

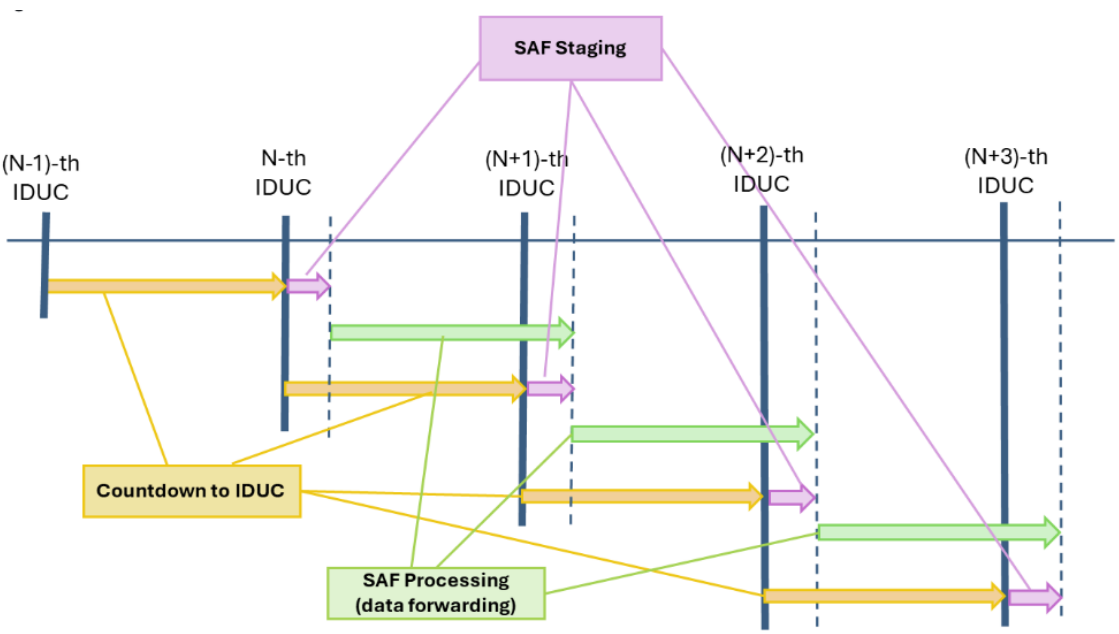

Figure. Cycles of IDUC, SAF staging, and processing projected in linear time view

Collecting event load statistics

1. Edit the following **objsvr_cred.sh** file to configure the ObjectServer username and password.

```
#!/bin/bash

USER=root
PASS=password

echo $USER $PASS
```

2. Edit the following **os_get_event_count.sh** file:

   - In the file, specify the time span for event count query. Configure the **query_interval_min** field.
   - In the file, specify an alert group for event count query. Configure the **MY_ALERT_GROUP** field.

```
#!/bin/bash

me="$(basename "$(test -L "$0" && readlink "$0" || echo "$0")")"

if [ $# -ne 1 ]; then
   echo "illegal number of parameters"
   echo "Usage: $me <object_server_name>"
   echo
   exit 0
fi

OBJSERV_NAME=$1

CRED=`./objsvr_cred.sh`
USER=`echo $CRED | awk -F' ' '{ print $1 }'`
PASS=`echo $CRED | awk -F' ' '{ print $2 }'`

# Configure the alert criteria of your choice
MY_ALERT_GROUP="AlertGroup='ConnectionStatus'"

omnihome="${OMNIHOME}"
sqllocation="./tmpsql"
mkdir -p $sqllocation

total_all_event_count=0
total_specific_event_count=0

start_time=0
query_interval_min=10 #in minutes
prev_epoch=0
sleep_interval=20 #in seconds

echo "Event count query for $query_interval_min mins"
query_interval_secs=$(( $query_interval_min * 60 ))

curr_timestamp=`date`
curr_epoch=`date +%s`
time_to_stop=$(( $curr_epoch + $query_interval_secs ))
echo "Current time: "${curr_epoch} "("${curr_timestamp}")"
echo "Time to stop: "${time_to_stop}
```

```
while :
do
   rand=`echo $RANDOM | base64 | head -c 20; echo`
   curr_epoch=`date +%s`

   if [[ $curr_epoch -gt $time_to_stop ]]
   then
      curr_timestamp=`date`
      echo "Query ends here. Time: "${curr_timestamp}
      exit 1
   fi
   if [[ $prev_epoch -eq 0 ]]
   then
      start_time=$curr_epoch
      prev_epoch=$(( $curr_epoch - $sleep_interval ))
   fi

   sttchg_window="StateChange>${prev_epoch} AND StateChange<=${curr_epoch}"
   select_condition=${sttchg_window}

   get_count_sqlfile_all="${sqllocation}/${rand}.get_count_all.sql"
   get_count_sqlfile_specific="${sqllocation}/${rand}.get_count_specific.sql"

   echo "select count(*) from alerts.status where ${select_condition}" >> ${get_count_sqlfile_all}
   echo "go" >> ${get_count_sqlfile_all}

   echo "select count(*) from alerts.status where ${select_condition} AND ${MY_ALERT_GROUP}" >>
${get_count_sqlfile_specific}
   echo "go" >> ${get_count_sqlfile_specific}

   echo "Show ${get_count_sqlfile_all} content:"
   cat ${get_count_sqlfile_all}
   echo
   echo "Show ${get_count_sqlfile_specific} content:"
   cat ${get_count_sqlfile_specific}
   echo

   all_count_result_file="${sqllocation}/${rand}.all_count_result.txt"
   ${omnihome}/bin/nco_sql -server ${OBJSERV_NAME} -user "${USER}" -password "${PASS}" < ${get_count_sqlfile_all} >
${all_count_result_file}

   specific_count_result_file="${sqllocation}/${rand}.specific_count_result.txt"
   ${omnihome}/bin/nco_sql -server ${OBJSERV_NAME} -user "${USER}" -password "${PASS}" <
${get_count_sqlfile_specific} > ${specific_count_result_file}

   all_evt_cnt_str=`sed -n '3p' < ${all_count_result_file}`
   all_curr_event_count=$(($all_evt_cnt_str))
   total_all_event_count=$(( $total_all_event_count + $all_curr_event_count ))

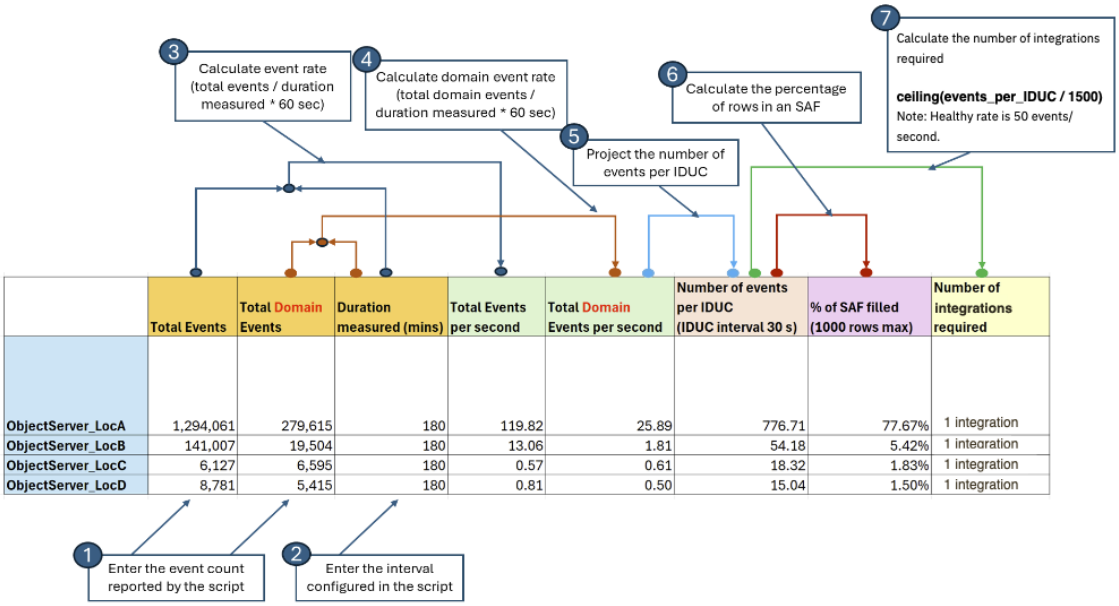
   specific_evt_cnt_str=`sed -n '3p' < ${specific_count_result_file}`
   specific_curr_event_count=$(($specific_evt_cnt_str))
   total_specific_event_count=$(( $total_specific_event_count + $specific_curr_event_count ))

   window_len=$(( $curr_epoch - $prev_epoch ))
   echo "Time window interval (secs): "${window_len}
   echo "All group event count for StateChange (${prev_epoch}:${curr_epoch}]: "${all_curr_event_count}
   echo "Total all group event count: "${total_all_event_count}
   echo "Specific group event count for StateChange (${prev_epoch}:${curr_epoch}]: "${specific_curr_event_count}
   echo "Total specific group event count: "${total_specific_event_count}

   rm -f $get_count_sqlfile_specific
   rm -f $get_count_sqlfile_all
   rm -f $all_count_result_file
   rm -f $specific_count_result_file

   prev_epoch=$curr_epoch

   echo "Sleep for "$sleep_interval" secs..."
   sleep $sleep_interval
   done
```



3. Run the **os_get_event_count.sh** script to collect event count statistics for all alerts and specific alerts.

   ```
   os_get_event_count.sh <ObjectServer_Name> > <output_file>
   ```

   Where

   - **<ObjectServer_Name>** is the name of your IBM Netcool Operations Insight ObjectServer. For example, **NCOMS**
   - **<output_file>** is the name of the output file where log of the script is saved. For example, **NCOMS_event_count.log**.

Calculating the number of integrations that are required for given load of domain alerts

	Total Events	Total Domain Events	Duration measured (mins)	Total Events per second	Total Domain Events per second	Number of events per IDUC (IDUC interval 30 s)	% of SAF filled (1000 rows max)	Number of integrations required
ObjectServer_LocA	1,294,061	279,615	180	119.82	25.89	776.71	77.67%	1 integration
ObjectServer_LocB	141,007	19,504	180	13.06	1.81	54.18	5.42%	1 integration
ObjectServer_LocC	6,127	6,595	180	0.57	0.61	18.32	1.83%	1 integration
ObjectServer_LocD	8,781	5,415	180	0.81	0.50	15.04	1.50%	1 integration

Figure. Number of integrations required to process the given load of domain alerts

Use the following steps to calculate the number of integrations that are required for given loads of domain alerts:

1. Enter the event count reported by the script.
2. Enter the interval configured in the script.
3. Calculate the event rate (total events / duration measured * 60 sec).
4. Calculate the domain event rate (total domain events / duration measured * 60 sec).
5. Project the number of events per IDUC.
6. Calculate the percentage of rows in an SAF.
7. Calculate the number of integrations required.

   Note: The following calculation assumes that you are using the default IDUC interval, which is 30 seconds. The formula is displayed:

   `ceiling(events_per_IDUC / 50 * IDUC interval)` => `ceiling(events_per_IDUC / 50 * 30)`

Configuring Integrations

Integrations enable IBM Cloud Pak for AIOps to collect data from various sources, then communicate how your IT operations are performing against a baseline model that is established by your AI models. To have a fully functioning instance of IBM Cloud Pak for AIOps, you must configure both outgoing and incoming integrations. It is worth noting that ServiceNow is bidirectional.

Note: Each integration that you configure requires an additional 1 vCPU and 3GB memory. For example, if you configure five integrations then you will require an additional 5 vCPUs and 15GB memory.

For more information about integrations in general, click the following links:

- Integrations UI
- Integration types

For more information about integrations in general, including at a minimum how to create, edit, and delete a particular integration, click the corresponding link in the following list:

- Ansible integrations
- Appdynamics integrations
- AWS CloudWatch integrations
- Custom integrations
- Dynatrace integrations
- ELK integrations
- Falcon LogScale integrations
- Instana integrations
- Kafka integrations
- Mezmo integrations
- Microsoft Teams integration
- Netcool integrations
- New Relic integrations

- Observer jobs
- Optional integrations
- PagerDuty integrations
- Slack integration
- ServiceNow integration
- Splunk integrations
- SSH integrations
- Zabbix integrations

For ancillary information on integrations, see:

- Prerequisites for loading data from WebSphere log data sources
- Certificate management

Integrations

Using the Integrations capability you can connect data sources to provide data that helps gather insights for your environment.

The main Integrations page now has two tabs: the *Manage integrations* tab, and the *Manage observer jobs* tab.

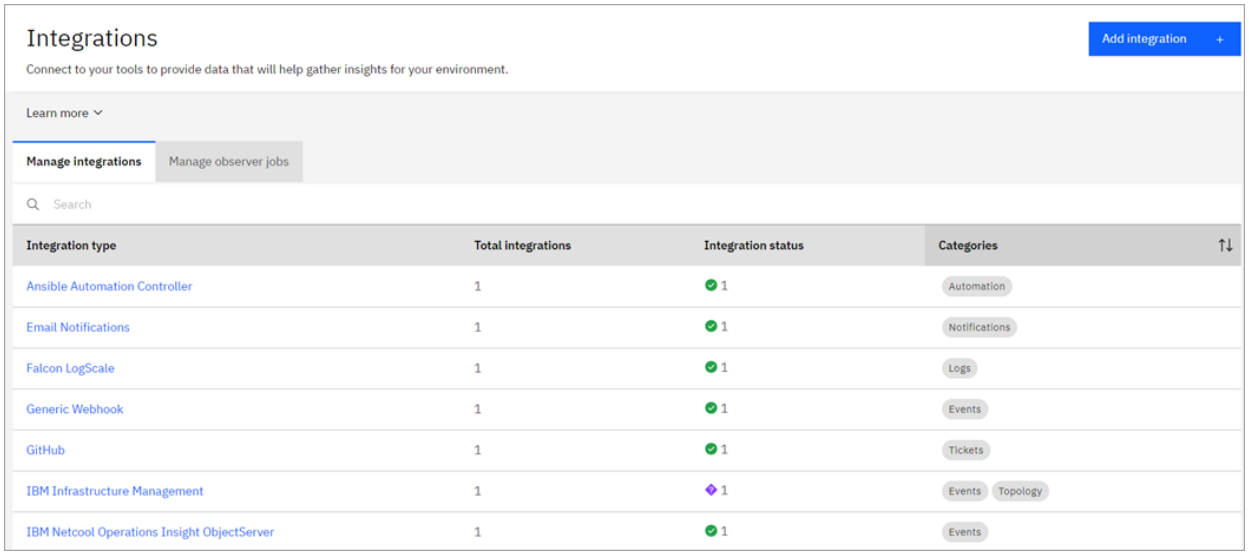


Figure. Manage integrations page

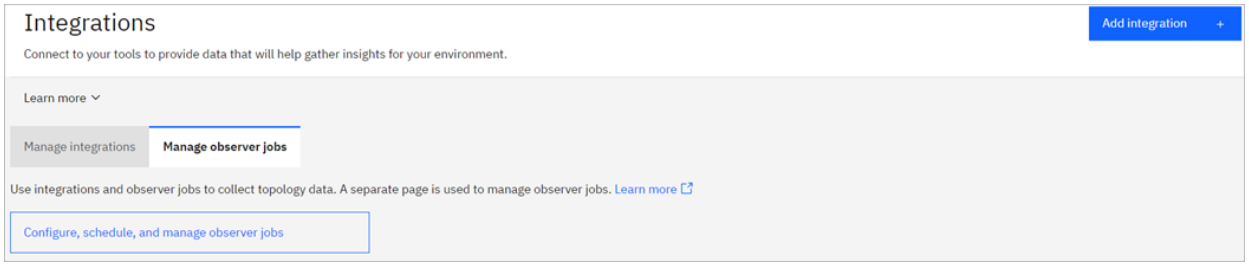
On the *Manage observer jobs* tab, you can configure, schedule and manage jobs, and use integrations and observer jobs to collect topology data.



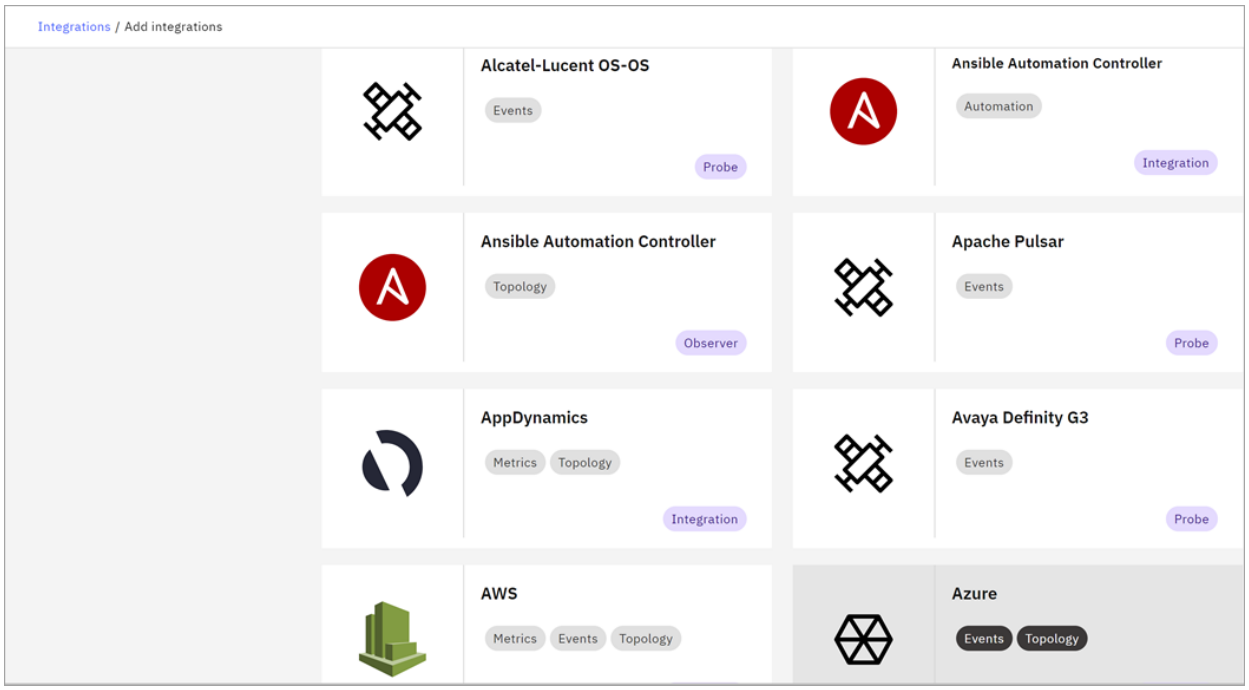


Figure. Manage observer jobs page

Incoming integrations provide data to IBM Cloud Pak for AIOps. Outgoing integrations report findings from IBM Cloud Pak for AIOps to supported ChatOps interfaces and ServiceNow. Some integrations are bidirectional. For example, to have a successfully operating instance of IBM Cloud Pak for AIOps, you might configure a Slack outgoing integration for ChatOps, a Falcon Logscsale incoming integration for log data, and a ServiceNow integration for change risk and similar ticket data.

Integrations UI

Outgoing integrations must be publicly accessible. If your cluster is behind a firewall, for example, it must be tunneled through something, such as Secure Tunnel. For more information about Secure Tunnel, see Using Secure Tunnel for ChatOps. If you previously exposed your host for one outgoing integration, you do not need to configure it for other outgoing integrations.

For more information about prerequisites for specific outgoing integrations, see the following topics:

- Configuring Microsoft Teams for integration
- Configuring Slack applications for integration
- Configuring the ServiceNow App for IBM Cloud Pak for AIOps
- Mapping data

Note: When you configure integrations for IBM Cloud Pak for AIOps, your browser might give you an option to save key, token, or password-type fields. For security purposes, do not save these values. Turn off autofill or autosave settings in your browser, or exercise caution with these features.

Integration types

Use this information to understand which data integrations to use to ingest different types of content.

Click the respective integration type that you want to learn more about creating, editing, and deleting that particular type of integration.

Integration types

Data source	Type of content supported	Link
Ansible	Runbooks, Remote Access	Ansible integrations
Appdynamics	Metrics	Appdynamics integrations
AWS CloudWatch integrations	Metrics	AWS CloudWatch integrations
Custom	Logs	Custom integrations
Dynatrace	Metrics	Dynatrace integrations
ELK	Logs	ELK integrations
Falcon LogScale	Logs	Falcon LogScale integrations
GitHub	Incident tickets	GitHub integrations
Instana	Events, Metrics, Topology	Instana integrations
Jira	Incident tickets	Jira integrations
Kafka	Logs, Events	Kafka integrations
Mezmo	Logs	Mezmo integrations
Microsoft Teams	ChatOps	Microsoft Teams integrations
Netcool	Events	Netcool integrations
New Relic	Metrics	New Relic integrations
PagerDuty	Events	PagerDuty integrations
ServiceNow	Change tickets, Incident tickets	ServiceNow integrations
Slack	ChatOps	Slack integrations
Splunk	Logs	Splunk integrations
SSH	Runbooks, Remote Access	SSH integrations

Data source	Type of content supported	Link
Zabbix	Metrics	Zabbix integrations

Outgoing integrations

Outgoing integrations enable IBM Cloud Pak for AIOps to communicate how your IT operations are performing against a baseline model that is established by you during model training. IBM Cloud Pak for AIOps uses this comparison to report anomalous activity to you in near real time.

Outgoing integrations must be publicly accessible. If your cluster is behind a firewall, for example, it must be tunneled through something, such as Secure Tunnel. For more information about Secure Tunnel, see Using Secure Tunnel for ChatOps. If you previously exposed your host for one outgoing integration, you do not need to configure it for other outgoing integrations.

When you set up your outgoing ChatOps integration, you must configure two channels: a *proactive channel* that you want to use for notifications (from change risk, for example), and a *reactive channel* that you want to use for incidents and alerts.

Note: The ServiceNow integration type has optional incoming and outgoing facets.

For more information about configuring ServiceNow, Slack, and Microsoft Teams for your integrations, see the following topics:

- Microsoft Teams integration
  - Configuring Microsoft Teams applications for integration
- Slack integration
  - Configuring Slack applications for integration
- ServiceNow integration
  - Configuring the ServiceNow App for IBM Cloud Pak for AIOps
- SSH integration
- Email integration
- Ansible integration

Creating a Microsoft Teams integration

A Microsoft Teams integration lets you and your team use collaborative ChatOps features to receive incident notifications. You can only connect to one ChatOps tool at a time, so if you already configured another ChatOps integration (such as Slack), you cannot connect to Microsoft Teams.

Prerequisites

Before you set up your Microsoft Teams integration, you must create your Azure Bot, and configure the Microsoft Teams application to communicate with IBM Cloud Pak for AIOps. For more information about configuring Microsoft Teams applications for IBM Cloud Pak for AIOps, see Configuring Microsoft Teams applications for integration.

Important: If you have an offline (air-gapped) deployment of IBM Cloud Pak for AIOps or an environment that uses a proxy server, then you cannot use the ChatOps Microsoft Teams integration. The use of a proxy with the ChatOps Microsoft Team integration is not supported.

Note: If the URL of the on-premises IBM Cloud Pak for AIOps instance can't be accessed by Microsoft Teams, you can use Secure Tunnel to expose the IBM Cloud Pak for AIOps instance to either a cluster (Red Hat OpenShift or IBM Kubernetes Service cluster) or a host machine (virtual machine or physical machine), which is accessible from the public network. Then, you can get a URL that can be accessed by Microsoft Teams. For more information about Secure Tunnel, see Using Secure Tunnel for ChatOps.

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating a Microsoft Teams integration

Note: To implement your Microsoft Teams integration, you need the Client Secret and ID information available either from Microsoft Teams or Microsoft Azure. Follow the steps that are outlined in Configuring Microsoft teams application for integration to acquire these variables.

To create a Microsoft Teams integration, complete these steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Microsoft Teams** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.

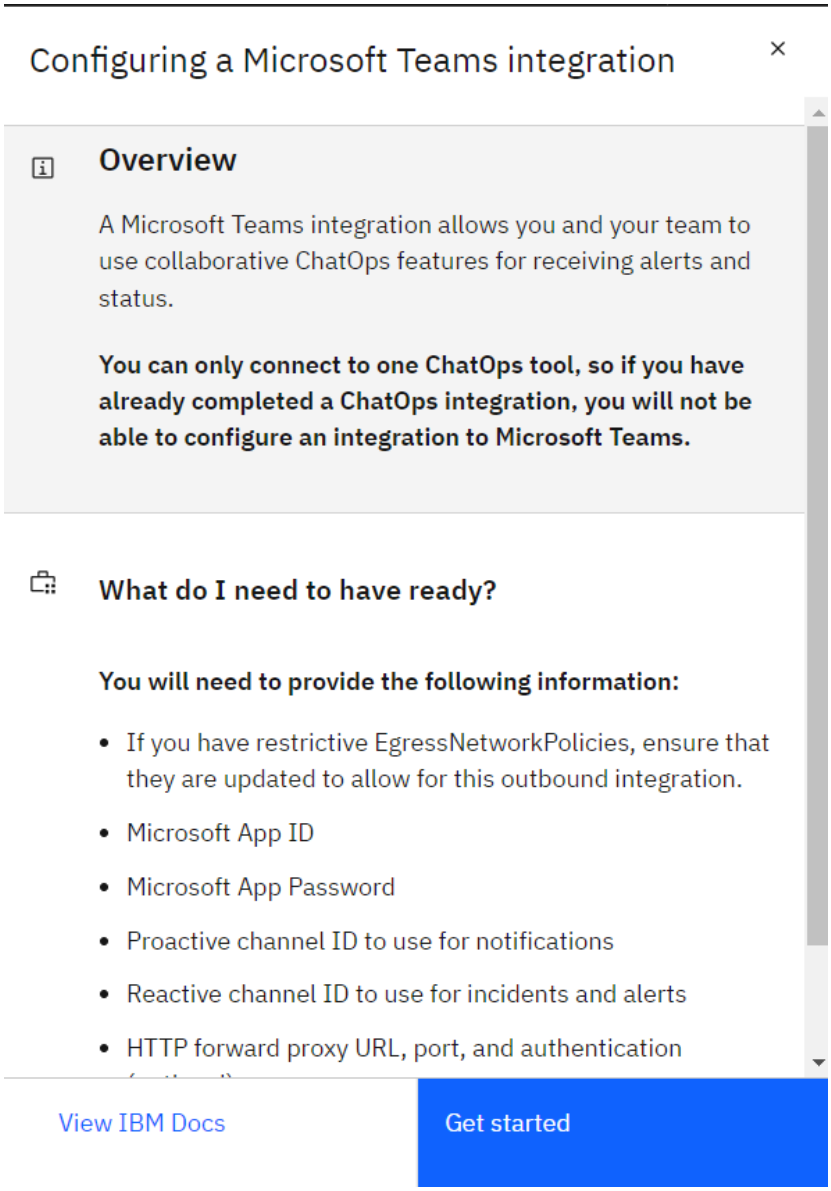

Figure. Configure Microsoft Teams integration

6. On the *Add integration* page, define the general integration details:

- **Name**: The display name of your integration.
- **Description**: An optional description for the integration.
- **Microsoft App ID**: Token for the bot that is associated with the app that is installed in a channel. You can copy this value from the *Microsoft APP ID* field on the Microsoft Teams **Settings** > **Configuration** page.
- **APP Password**: Enter the Azure Bot client secret for the integration.

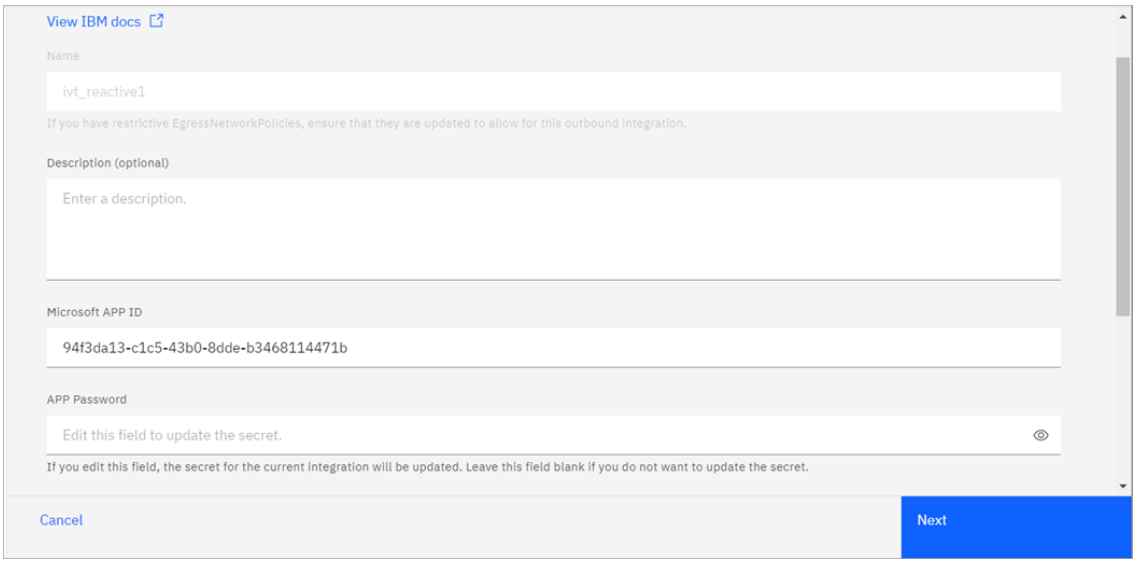

Figure. Create Microsoft Teams integration

- **Language ID**: Select your language from the drop-down list.
- **Proactive channel**: The channel ID for the channel that you want to use for notifications (from change risk, for example). For more information about obtaining channel ID values, see Obtaining links to your channels.
- **Reactive channel**: The channel ID for the channel that you want to use for incidents and alerts. For more information about obtaining channel ID values, see Obtaining links to your channels.

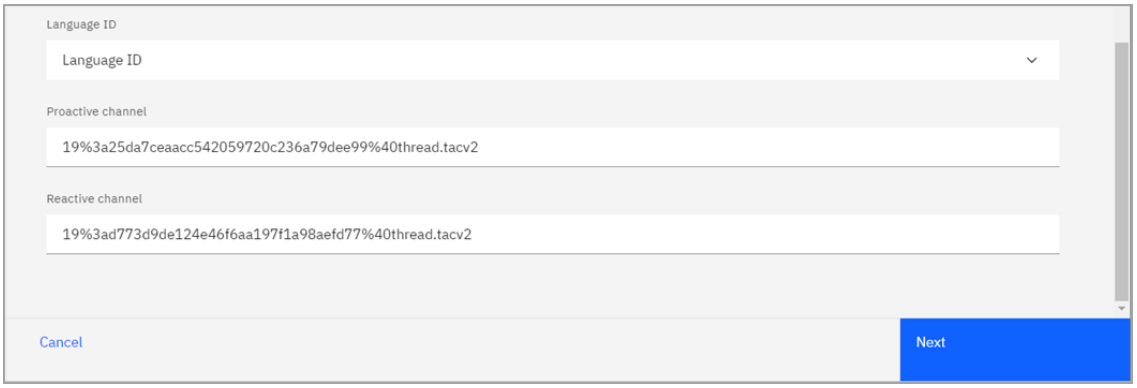

Figure. Microsoft Teams integration

Click **Next**.

Important: On the optional **Configure Proxy** page, do not toggle the *Enable Proxy* selection to configure a proxy. This does not work for Microsoft Teams integrations. For more information, see Known Issues.

You can test your integration by clicking **Test connection**.

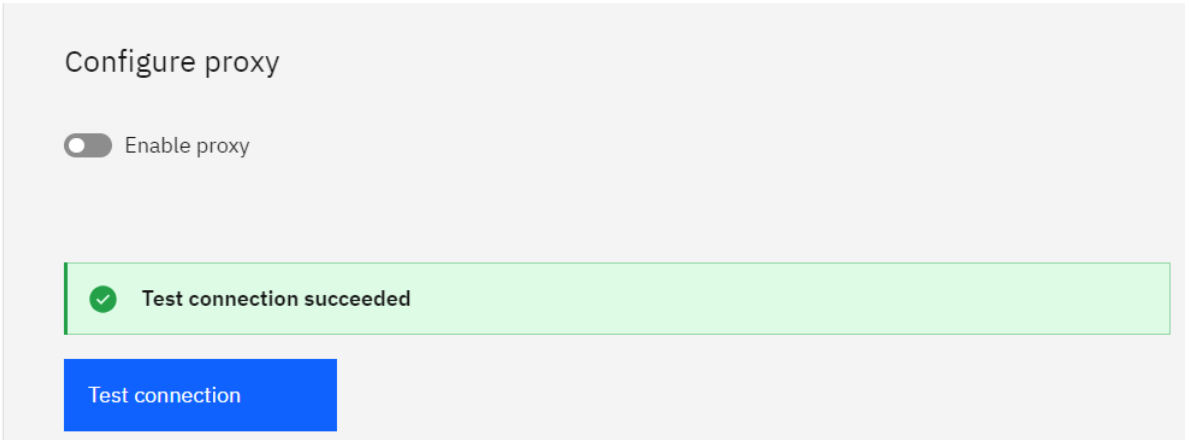

Figure. Test connection

Note: Your secret must be fully registered on Microsoft Azure for the integration to pass. If you test your integration immediately after creating the secret, wait a couple of minutes, then try again.

7. Click **Save**.

You have created a Microsoft Teams integration in your instance. Unlike a log or event integration, you do not need to enable a ChatOps integration after creating it. Once you create the integration and set up Microsoft Teams, you can verify that everything is working by issuing test commands in Microsoft Teams. For more information about verifying your integration, see Enabling your bot and adding it to your channel.

To create more integrations, see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Connecting the Azure Bot to IBM Cloud Pak for AIOps

Before you can finish implementing your Azure Bot in Microsoft Teams, you must create your integration at the instance level in IBM Cloud Pak for AIOps. Creating an integration in IBM Cloud Pak for AIOps provides the URL for the messaging endpoint. After this step, you can edit the Microsoft Teams integration to complete setting it up, but the URL for the messaging endpoint is required to complete your Azure Bot registration.

1. Create a Microsoft Teams integration.
2. From the Cloud Pak for AIOps console, click the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Microsoft Teams** integration type in the *Manage integrations* tab. On the *Microsoft Teams* page, copy the request URL from the *Details* column. This URL is required to enable two-way communication between Microsoft Teams and IBM Cloud Pak for AIOps.

   Note: If you used Secure Tunnel to expose the IBM Cloud Pak for AIOps for Microsoft Teams integration, you need to replace the **`request URL`** with the application mapping URL.

   To get the application mapping URL, go to **Administration** > **Secure Tunnel** from the navigation menu (four horizontal bars). On the **Manage integrations** tab, find the tunnel integration, and click the integration name. In the **Application mappings** page, copy the application mapping URL from the **IBM Cloud Pak for AIOps mapping URL** field. For more information, see Viewing Secure Tunnel.
4. Log back into your Microsoft Azure home page and navigate to the *Configuration* section of your Azure Bot resource.
5. Paste the request URL from the *Details* column of the IBM Cloud Pak for AIOps *Microsoft Teams instances* page into the *Messaging endpoint* field on the *Configuration* section of your Azure Bot resource in Microsoft Azure. Click **Save**.

Enabling your Azure Bot and adding it to your channel

After you set up your Microsoft Teams integration, you can download the Microsoft Teams Azure Bot through the instance interface in the IBM Cloud Pak for AIOps console.

Note: The same Azure Bot must be added to both your reactive and proactive channels.

To download the Azure Bot, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Microsoft Teams* tile, click **1 instance**.
4. On the *Microsoft Teams instances* page, click the options menu (three vertical dots), then click **Download bot app**. Save **`IBM_Cloud_Pak_AIOps.zip`** to an accessible local directory.
5. Log in to Microsoft Teams to upload your Azure Bot to your channel. Click **Apps** in the sidebar.
6. Click **Upload a custom app**. Select the compressed file that you downloaded. The IBM Cloud Pak for AIOps Azure Bot appears in the *Built by your org* section.
7. Click the IBM Cloud Pak for AIOps tile, then click **Add**.
8. The tile is on the *Apps* page. Click the IBM Cloud Pak for AIOps tile on the *Apps* page. The IBM Cloud Pak for AIOps details page opens.
9. Click the drop-down arrow next to *Open*, then click **Add to a team**. Select the team that you designated to be the appropriate channel to post to (either your reactive or proactive channel). Click **Set up a bot**.

You have edited your integration.

The channel that you set up opens and the Azure Bot is fully functional.

You can verify that everything is operating as expected by issuing the welcome command for the Azure Bot in Microsoft Teams:

- **`@<bot_name> /waiops_welcome`**: provides a welcome message about using the bot, where **`bot_name`** is the name of your Azure Bot.

Editing a Microsoft Teams integration

After you create your integration, you can edit the integration. For example, if you want to change which channel your proactive messages are routed to, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.

3. Click the **Microsoft Teams** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Microsoft Teams integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration. Click **Next** to go through the integration configuration pages.

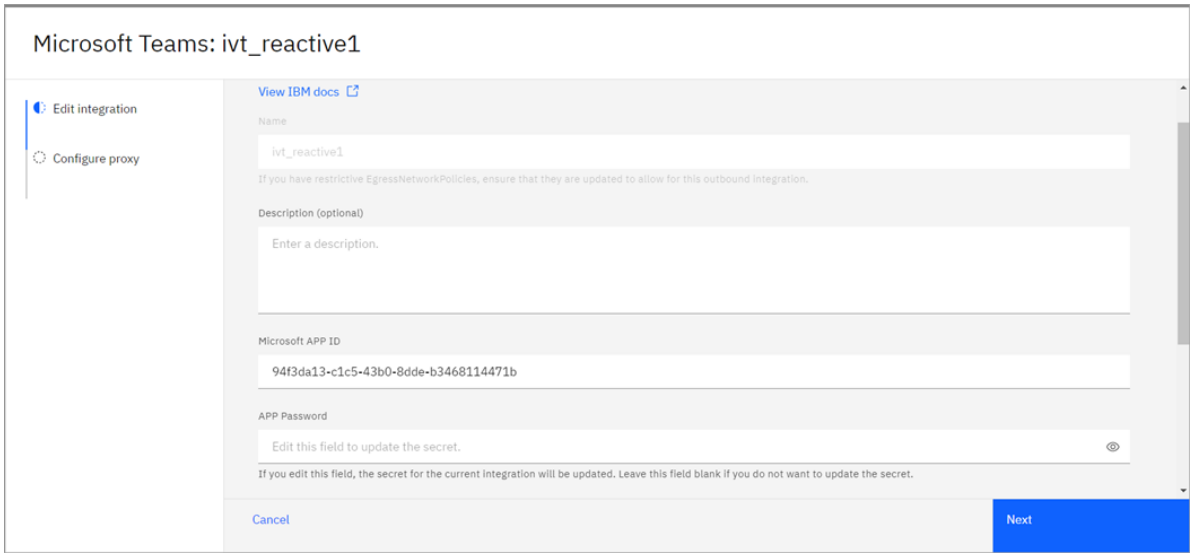

Figure. Edit Microsoft Teams integration

6. Click **Save** when you are done editing.

Note: Updating a ChatOps integration with a new Microsoft Teams Azure bot can result in disconnected ChatOps incidents. Existing incidents that were posted by a different bot do not receive any more updates. You are recommended to use the same bot resource when possible.

Deleting a Microsoft Teams integration

If you no longer need your Microsoft Teams integration, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Microsoft Teams** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Microsoft Teams integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Configuring Microsoft Teams application for integration

IBM Cloud Pak for AIOps supports a direct integration to your enterprise Microsoft Teams installation.

To complete your Microsoft Teams integration in IBM Cloud Pak for AIOps, you need to obtain these credentials:

- Client secret
- Microsoft App ID
- Proactive channel ID
- Reactive channel ID

Prerequisites

- A Microsoft Azure account with the ability to create an Azure Bot and client secrets for your bot
- A Microsoft Teams account that you can create channels and add applications to

For more information about completing your Microsoft Teams integration, see Creating a Microsoft Teams integration.

Configuring Microsoft Teams

For a Microsoft Teams application integration, you must

1. Create an Azure bot resource
2. Enable Teams integration
3. Acquire integration credentials

1. Create an Azure bot resource

1. Log in to your Microsoft Azure home page.
2. Click **Create a resource**.
3. In the **Create a resource** search box, enter *Azure Bot* and select it from the list of available resources.
4. On the **Azure Bot** page, click **Create**.
5. When the create page opens, give the bot a name in the *Bot handle* field. This handle is used for tracking in Azure.
6. Next, from the dropdown menus, select a valid **Subscription** and **Resource** group.
7. In *Type of app*, select **Multi Tenant**.
8. At the bottom of the page, click **Next: Tags >**.
9. On the next page, enter any tags that you want to add in the **Tags** tab or skip and click **Review+create** tab.
10. Your submitted configuration is now validated and you can click the **Create** button.

The Azure Bot resource is now created. If you return to the Microsoft Azure home page, you see that the new Azure Bot resource is in the *Recent resources* section.

After creating and validating the Azure Bot resource, a notification appears about the deployment status. Click the notification **Deployment in progress**... to view the status of the resource, then **Go to resource** from the notification to manage your new resource.

2. Enable Teams communication

Retrieve the Azure Bot resource by going to the Microsoft Azure home page and clicking the *Recent resources* section. Alternatively, find the resource by entering the Azure Bot handle of the resource into the search box. Then, complete these steps:

1. From the resource page, click **Settings**. Go to the *Configuration* section.
2. Click **Channels**.
3. In the *Add a featured channel* section, click the Microsoft Teams icon. The *Configure Microsoft Teams* page opens.
4. Click **Save**, then accept the Terms of Service and click **Agree**.

The Azure Bot is now ready to connect to Microsoft Teams but before you implement the Azure Bot you must obtain the remaining information for your Microsoft Teams integration in IBM Cloud Pak for AIOps.

3. Acquire integration credentials

Retrieve the credentials of the Azure Bot resource by going to the Microsoft Azure home page and clicking the *Recent resources* section. Alternatively, find the resource by entering the Azure Bot handle of the resource into the search box.

From the resource page, then click **Settings** to access each of the credentials

- *Microsoft App ID*: Click **Configuration** > **Microsoft App ID**
- *Client Secret*: Click **Configuration** > **Microsoft App ID**. Click **Manage** > **New client secret**. (**Note:** This information is viewable only once, so make sure you copy the actual secret and not the ID.)

Proactive & Reactive Channel IDs: The instructions for both are the same, just with two different channels:

1. Log in to Microsoft Teams.
2. Click the options icon (three horizontal dots) next to the channel name for the channel that you want to use for your integration (proactive or reactive). Click **Get link to the channel**.
3. The channel ID is not the entire URL provided by the preceding step. To extract the channel ID from the URL, grab the string between channel/ and the next /.

   Example: `https://teams.microsoft.com/l/channel/19%3a7b1d2sldfglkjsdfhg73402d63%40thread.tacv2/...` In this example, the channel ID would be: `19%3a7b1d2sldfglkjsdfhg73402d63%40thread.tacv2`.

Now that you have created your Azure Bot and noted down the credentials, you have the required information for Creating a Microsoft Teams integration.

Creating a Slack integration

A Slack integration allows you and your team to use collaborative ChatOps features for receiving incident alerts and status. You can only connect to one ChatOps tool at a time, so if you already configured another ChatOps integration (such as Microsoft Teams), you won't be able to connect to Slack.

On the *Manage integrations* tab you can create, edit, and delete integrations.

Before you set up your Slack integration, you must create your bot and configure Slack to communicate with IBM Cloud Pak for AIOps. For more information about configuring a Slack application, see Configuring Slack applications for integration.

Note: If the URL of the on-premises IBM Cloud Pak for AIOps instance can't be accessed by Slack, you can use Secure Tunnel to expose the IBM Cloud Pak for AIOps instance to either a cluster (Red Hat OpenShift or IBM Kubernetes Service cluster) or a host machine (virtual machine or physical machine), which is accessible from the public network. Then, you can get a URL that can be accessed by Slack. For more information about Secure Tunnel, see Using Secure Tunnel for ChatOps.

For more information about working with a Slack integration, see the following sections:

- Creating a Slack integration
- Editing a Slack integration
- Deleting a Slack integration

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating a Slack integration

To complete your Slack integration, you need the following information:

- Signing secret
- Bot User OAuth Access Token
- Proactive channel ID
- Reactive channel ID
- If you have an offline (air-gapped) deployment of IBM Cloud Pak for AIOps , then you must have the details of a proxy server that you have set up for IBM Cloud Pak for AIOps to connect to Slack.

Obtaining these values require you to have the following prerequisites:

- Slack
- API authentication to your Slack instance
- If you have an online deployment of IBM Cloud Pak for AIOps, network connectivity between the IBM Cloud Pak for AIOps instance and the Slack Enterprise edition instance

  Note: If a direct endpoint cannot be established, you can use Secure Tunnel to securely tunnel between the two. For more information about Secure Tunnel, see Using Secure Tunnel for ChatOps.

Important: You can only create one ChatOps integration (Microsoft Teams or Slack) per instance.

For more information about setting up and configuring Slack for integration, see Configuring Slack for integration.

To create a Slack integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Slack** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration. If you have any restrictive EgressNetworkPolicies in place, ensure that they are updated to allow for this outbound integration.
   - **Description**: An optional description for the integration.
   - **Signing secret**: The secret that is generated for the client. You can copy this value from the *App Credentials* section inside the *Basic Information* page of the Slack application. For more information about obtaining this value, see Configuring your Slack app. If you edit this field, the secret for the current integration is updated. Leave this field blank if you do not want to update the secret.
   - **Bot token**: Token for the bot that is associated with the app that is installed in a workspace. You can copy this value from the *Install App* section in the Slack application. For more information about obtaining this value, see Configuring your Slack app. If you edit this field, the secret for the current integration is updated. Leave this field blank if you do not want to update the secret.
   - **Language ID**: A dropdown list offering various different languages options for the integration.
   - **Proactive channel**: Enter a proactive channel for the integration. The channel ID for the channel that you want to use for notifications (from change risk, for example). For more information about obtaining channel ID values, see Obtaining links to your channels.
   - **Reactive channel**: Enter a reactive channel for the integration. The channel ID for the channel that you want to use for incidents and alerts. For more information about obtaining channel ID values, see Obtaining links to your channels.
7. Click **Next**.

   On the optional *Configure Proxy* page, toggle the *Enable Proxy* selection to on if you require a proxy server to connect to Slack, and enter the following information:

   - **Proxy URL**: The hostname of your proxy server
   - **Proxy Port**: The port number
   - **Proxy username**: The proxy server username
   - **Proxy password**: The proxy server password

Figure. Create Slack integration - configure proxy

You can test your integration by clicking **Test connection to Slack.com**.

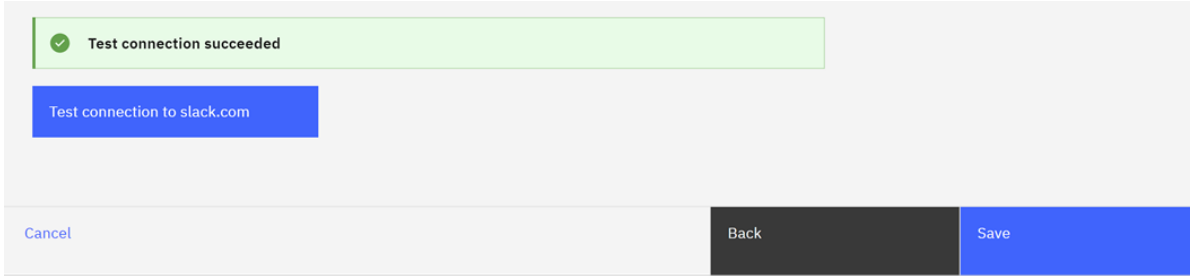

Figure. Test connection

8. Click **Done**.

You create a Slack integration in your instance. Unlike log or event integration, you do not need to enable ChatOps integrations after creating them.

To create more integrations, see Configuring Integrations.

For more information about working with the insights provided by your integration, see ChatOps insight management.

Editing a Slack integration

After you create your integration, your can edit the integration. For example, if you want to change which channel your proactive messages are routed to, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Slack** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Slack integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.

   Note: The integrations status in the *Manage integrations* tab might not display the status of your Slack integration. When you are editing a Slack integration, click the **Test connection** button to ensure that your credentials are correct.

   You can also test your integration by going to the target channel in Slack and entering `/welcome`. IBM Cloud Pak for AIOps responds with a welcome message in Slack.
5. Edit your integration. Click **Next** to go through the integration configurationn pages. Click **Save** when you are done editing.

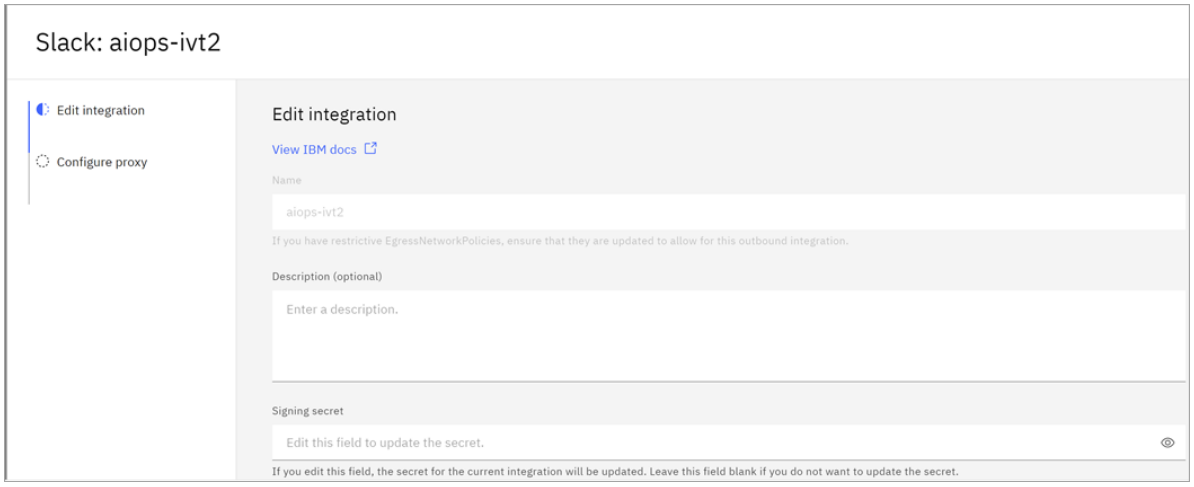

Figure. Edit Slack integration

Your integration is now edited. For more information about deleting a integration, see Deleting a Slack integration.

Note: Updating a ChatOps integration with a new Slack app can result in disconnected ChatOps incidents. Existing incidents that were posted by a different app do not receive any more updates. You are recommended to use the same app resource when possible.

Deleting a Slack integration

If you no longer need your Slack integration, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Slack** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Slack integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Configuring Slack applications for integration

IBM Cloud Pak® for AIOps supports a direct integration to your enterprise Slack installation.

Prerequisites

The following requirements are necessary to setting up a Slack integration:

- Slack
- API authentication to your Slack instance
- A valid certificate (not self-signed) for your publicly exposed Red Hat OpenShift Container Platform route
- If you have an offline (air-gapped) deployment of IBM Cloud Pak for AIOps , then you must have the details of a proxy server that you have set up for IBM Cloud Pak for AIOps to connect to Slack.
- If you have an online deployment of IBM Cloud Pak for AIOps, network connectivity between the IBM Cloud Pak for AIOps instance and the Slack Enterprise edition instance.

  Note: If a direct endpoint cannot be established, you can use Secure Tunnel to securely tunnel between the two. For more information about Secure Tunnel, see Using Secure Tunnel for ChatOps.

Creating your Slack app

Complete the following steps to configure your Slack integration.

Note: Be careful which workspace that you use. You must either be a workspace administrator – or wait for approval from the workspace administrator – when you interact with some of Slack's administrative settings.

Important: IBM Cloud Pak for AIOps requires two Slack channels, one for *proactive* notifications and one for *reactive* notifications. You must configure two channels, one for each purpose.

1. Identify the Slack channel that you want to connect:
    1. Create or use an existing Slack channel.
    2. Retrieve the **`channel ID`**. Right-click the channel name, then click **Copy Link** to get the web URL link. The last part of the link is the **`channel ID`**, starting with *C* for public channels or *G* for private channels.
2. Create a Slack app on https://api.slack.com/apps
    1. Click **Create New App**.
    2. Enter an App Name, and specify the workspace that you want to connect the app to, then click **Create App**.

Configuring your Slack app

1. After you create your Slack app from the Slack API page, click the name of the app that you created, then click **Features** > **App Manifest**.
2. Replace the contents of the manifest file (YAML) with the following (make sure you update the **`<app name>`** to your own app name) and save the changes.

```
_metadata:
   major_version: 1
   minor_version: 1
display_information:
   name: <app name>
features:
   bot_user:
         display_name: <app name>
         always_online: false
oauth_config:
   scopes:
      user:
         - channels:history
         - chat:write
         - groups:history
      bot:
         - app_mentions:read
         - channels:manage
         - channels:read
         - chat:write
         - files:write
         - groups:read
         - groups:write
         - users:read
         - users:read.email
         - commands
         - mpim:read
settings:
   org_deploy_enabled: false
```

   This manifest adds the following bot token to your application:

   - **`app_mentions:read`**
   - **`channels:manage`**
   - **`channels:read`**
   - **`chat:write`**
   - **`files:write`**
   - **`groups:read`**
   - **`groups:write`**
   - **`users:read`**
   - **`users:read.email`**
   - **`commands`**

   To validate your changes were saved, you can navigate to **Features** > **OAuth, & Permissions** and review the *Bot Scopes* section.
3. Go to the *Settings* > *Install App* page and go to the OAuth Tokens for Your Workspace section.
    1. Click **Install to Workspace**.
    2. Review the information and click **Allow**. Note that you must reinstall your application every time you change the scope.
    3. Record the Bot User OAuth Token found in the *OAuth Tokens for Your Workspace* section.
4. On the **Settings** > **Basic information** page, go to select *App Credentials* section and record the *Signing Secret* value.
5. Using your Slack desktop application, create and name two Slack channels under your Slack workspace:
    - Proactive channel (for example, **`aiops-proactive`**)
    - Reactive channel (for example, **`aiops-reactive`**)

   Retrieve the channel ID for both channels. Right-click the channel name, then click **Copy link** to get the web URL link. The last part of the link is the channel ID (Such as **`C020EA7QWLS`**). You need these values in following steps.
6. Log in to the IBM Cloud Pak for AIOps console.
7. From the main navigation menu (four horizontal bars in the upper-left), expand **Define**, and click **Integrations**. On the *Integrations* page, click **Add integration**.
8. Select *ChatOps* in the *Category* list (on the left), and click the **Slack** tile. On the side-panel, review the instructions and when ready to continue, click **Next**.
9. Enter the following information on the Slack integration definition page:
    - **`Name`**: The display name of your integration (Such as Slack Chat Ops)

- **`Description`**: An optional description for the integration.
- **`Signing secret`**: The signing secret generated for the client. You can copy this value from the App Credentials section inside the *Basic Information* page of the Slack application.
- **`Bot token`**: This is the token value for the bot that you recorded earlier. You can copy this value from the *Settings* > *Install App* page section in the Slack application.
- **`Language ID`**: A dropdown list offering various different languages options for the integration.
- **`Proactive channel`**: The channel ID for the channel that you want to use for notifications. You recorded this value in step 5.
- **`Reactive channel`**: The channel ID for the channel that you want to use for incidents and alerts. You recorded this value in step 5.

On the optional **Configure Proxy** page, toggle the *Enable Proxy* selection to on if you require a proxy server to connect to Slack, and enter the following information:

- **`Proxy URL`**: The hostname of your proxy server
- **`Proxy Port`**: The port number
- **`Proxy username`**: The proxy server username
- **`Proxy password`**: The proxy server password

10. Test your Slack integration integration by clicking **Test connection**. This test verifies that IBM Cloud Pak for AIOps can communicate with Slack (though it does_not_verify if Slack can communicate with IBM Cloud Pak for AIOps). If the test fails, review all preceding steps described previously.

11. Click **Done**.

12. From the Slack application page, go to *Features* > *App Manifest*. Complete the following updates to the contents of the manifest YAML.

    - Under the *settings* element, add the following child items. Ensure that you update the **placeholders**. The **`<request URL>`** value is the URL that you get from the console on the Integrations. For example, **`https://myibm.com/aiops/aimanager/instances/1647499820476511/api/slack/events`**. You can also get the value from the secure tunnel section Using Secure Tunnel for ChatOps.

      ```
      event_subscriptions:
         request_url: <request url>
         bot_events:
            - app_mention
            - member_joined_channel
      interactivity:
            is_enabled: true
            request_url: <request url>
      ```

      `event_subscriptions` and **`interactivity`** are at the same level in the configuration as the **`org_deploy_enabled`** and **`socket_mode_enabled`** elements.

    - Under the **`features`** element, add the following child item. Ensure that you update the **placeholders**.

      ```
      slash_commands:
         - command: /welcome
            url: <request url>
            description: Welcome to IBM Cloud Pak for AIOps
            should_escape: false
      ```

      `slash_commands` is at the same level in the configuration as the **`bot_user`** element.

13. Verify the Request URL. Click **Click here to verify link**. If this URL verification is not successful, review all preceding steps and ensure that the Request URL is correct.

14. Using the Red Hat OpenShift command line, run the following commands for the changes to take effect:

    ```
    oc project <namespace>
    ```

    Where **`<namespace>`** is the namespace where IBM Cloud Pak for AIOps is installed.

    ```
    oc set env deployment/$(oc get deploy -l app.kubernetes.io/component=chatops-slack-integrator -o
    jsonpath='{.items[*].metadata.name }') SLACK_WELCOME_COMMAND_NAME=/welcome
    ```

15. After the Slack application is configured, it must be reinstalled, as several permissions changed. Go to *Settings* > *Install App* page and click **Reinstall to Workspace**. On the subsequent page, click **Allow**.

16. Add the Slack application to **both** channels that you created earlier, such as your *proactive* and *reactive* channels.

    - Using your Slack desktop application, open the *Details* view of the channel, click **Integration** > **Add apps**, and add the Slack application to the channel. (The channel's *Details* view is found by clicking the small down-arrow next to the channel's name in the Slack UI.)
    - After you add the application to the channel, send the message **`/welcome`** to the channel. As a response, you can get a welcome message posted to the channel, which confirms the integration was made successfully.

You can now use Slack as your ChatOps interface. For more information about using the ChatOps interface, see ChatOps insight management.

Configuring the ServiceNow App for IBM Cloud Pak for AIOps

Before you set up your ServiceNow integration in IBM Cloud Pak® for AIOps, you must set up the IBM Cloud Pak for AIOps ServiceNow App in your ServiceNow instance.

About this task

With this integration, Cloud Pak for AIOps incidents and the alerts they're comprised of, can be sent to ServiceNow. Both the incidents and alerts contain the same details as their Cloud Pak for AIOps counterparts. To set up this integration, you must set up ServiceNow and the ServiceNow integration in Cloud Pak for AIOps.

Once configured, incidents and alerts sent to ServiceNow receive live updates to relevant fields. For incidents, this includes: title, description, state, and priority values. For alerts, this includes summary, severity, state, event count, and last occurrence values. Additionally, you can set up data synchronization so that updates made from ServiceNow are sent back to Cloud Pak for AIOps. For details on configuring data synchronization, see Creating a ServiceNow integration.

Prerequisites

Before you can set up ServiceNow to connect with IBM Cloud Pak for AIOps, you need to make sure that your ServiceNow instance meets the following requirements:

- Install the IBM Cloud Pak for AIOps App into your ServiceNow instance. To get the app, go to the ServiceNow Store.
- Your ServiceNow application must be version 4.4.0 to connect with IBM Cloud Pak® for AIOps version 4.8.0. This integration is not supported for earlier versions of the ServiceNow application.

Procedure

Complete the following steps to set up ServiceNow for integration:

1. Assign the managing roles for granting access to ServiceNow.
2. Create the users that need to access and set up the integration.
3. Create the ServiceNow integration with the IBM Cloud Pak for AIOps UI

Managing roles

In ServiceNow, two preset roles can be assigned to users: **`user_admin`** and **`itil`**. These roles can be added to the existing roles in the IBM Cloud Pak for AIOps App to grant more access to ServiceNow functions.

- The **`user_admin`** role gives privileges to create new users and assign roles to users.
  - Adding this role is optional. Not having this role does not affect functioning.
- The **`itil`** role gives access to the incident and change ticket views.
  - This role is required to view the IBM Cloud Pak for AIOps incidents and change risk assessments.

1. Log in to your ServiceNow custom application.
2. In the filter field, search for **`roles`**.
3. Click **User Administration** > **Roles**.
4. Search for **`x_ibm_waiops`**, which produces a list of predefined roles.

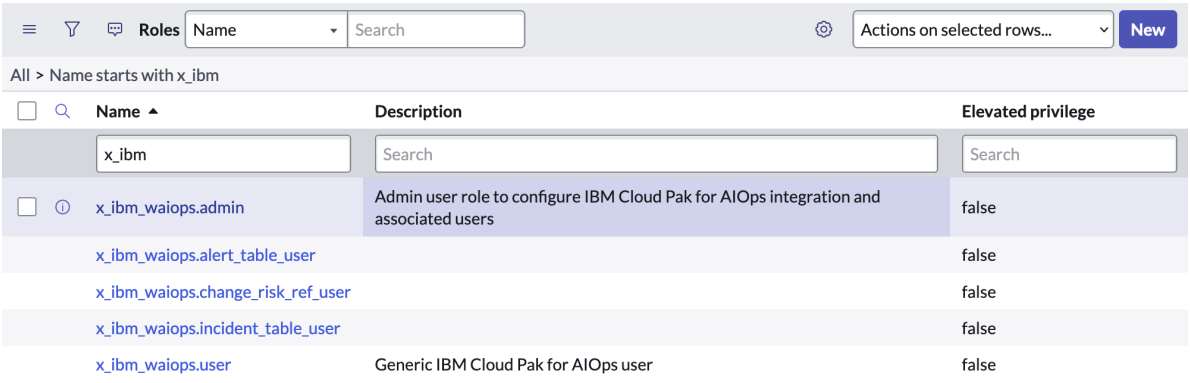

Figure. ServiceNow title list

5. Click **`x_ibm_waiops.admin`**.
6. **Optional:** Under the *Contains Roles List* box, select **Edit**, and you can add the **`user_admin`** role to the **`x_ibm_waiops.admin`** role.

   It looks like the following:

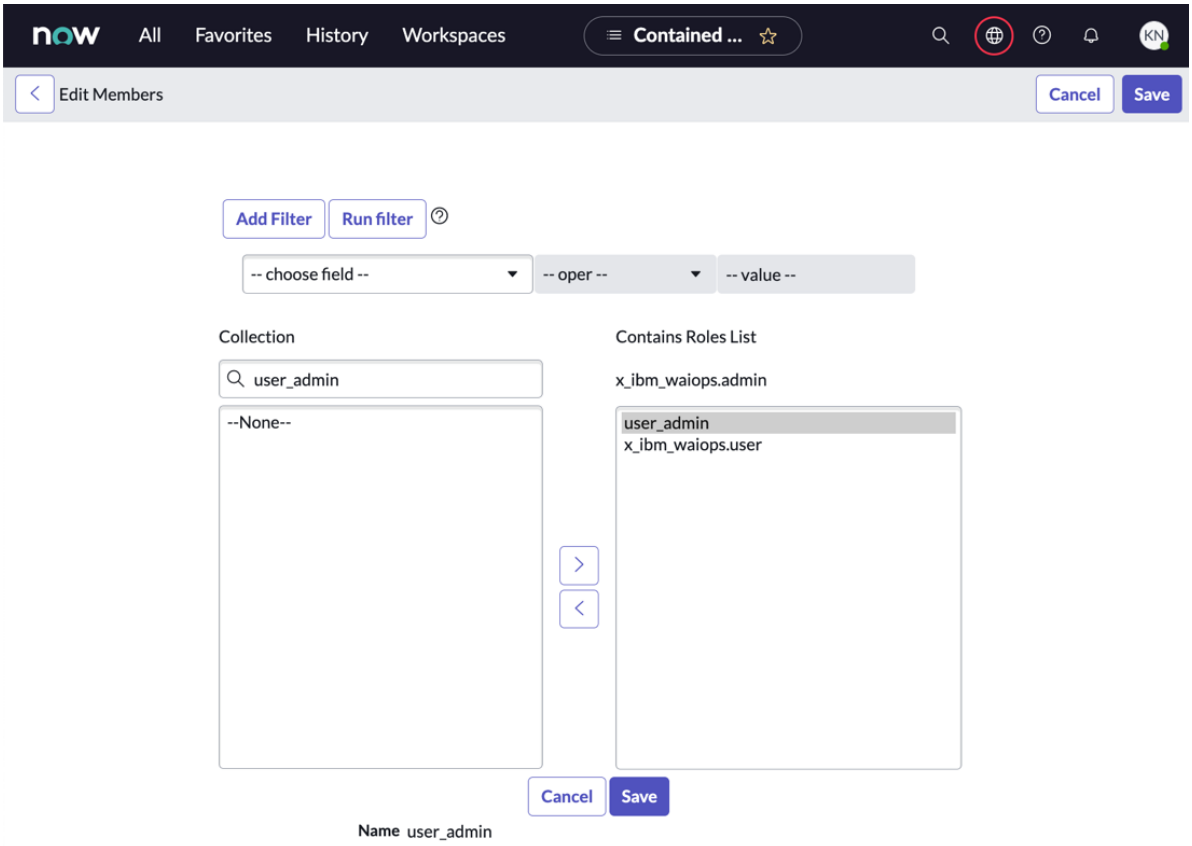

Figure. ServiceNow edit members

7. Go back to the list of predefined roles. Select **`x_ibm_waiops.user`**.
8. In the *Contains Roles List* box, select **Edit** and add the **`itil`** role to **`x_ibm_waiops.user`**. Unlike the **`user_admin`** role, this role is required.
    - Make sure that your IBM Cloud Pak for AIOps users in ServiceNow are assigned either the **`x_ibm_waiops.admin`** or the **`x_ibm_waiops.user`** role. The **`x_ibm_waiops.admin`** role includes the **`x_ibm_waiops.user`** role, so it inherits the **`itil`** role. All IBM Cloud Pak for AIOps users need the **`itil`** role to view generic incidents and change tickets. Without either the **`x_ibm_waiops.admin`** or the **`x_ibm_waiops.user`** roles, a user cannot access the augmented incidents and change tickets from the IBM Cloud Pak for AIOps ServiceNow App and receives a permissions error.
    - The other three roles available within the **`x_ibm_waiops.user`** role (all of which begin with **`x_ibm_waiops.`**) provide access to the three new tables introduced by the IBM Cloud Pak for AIOps ServiceNow App.
9. Now you see something like this:

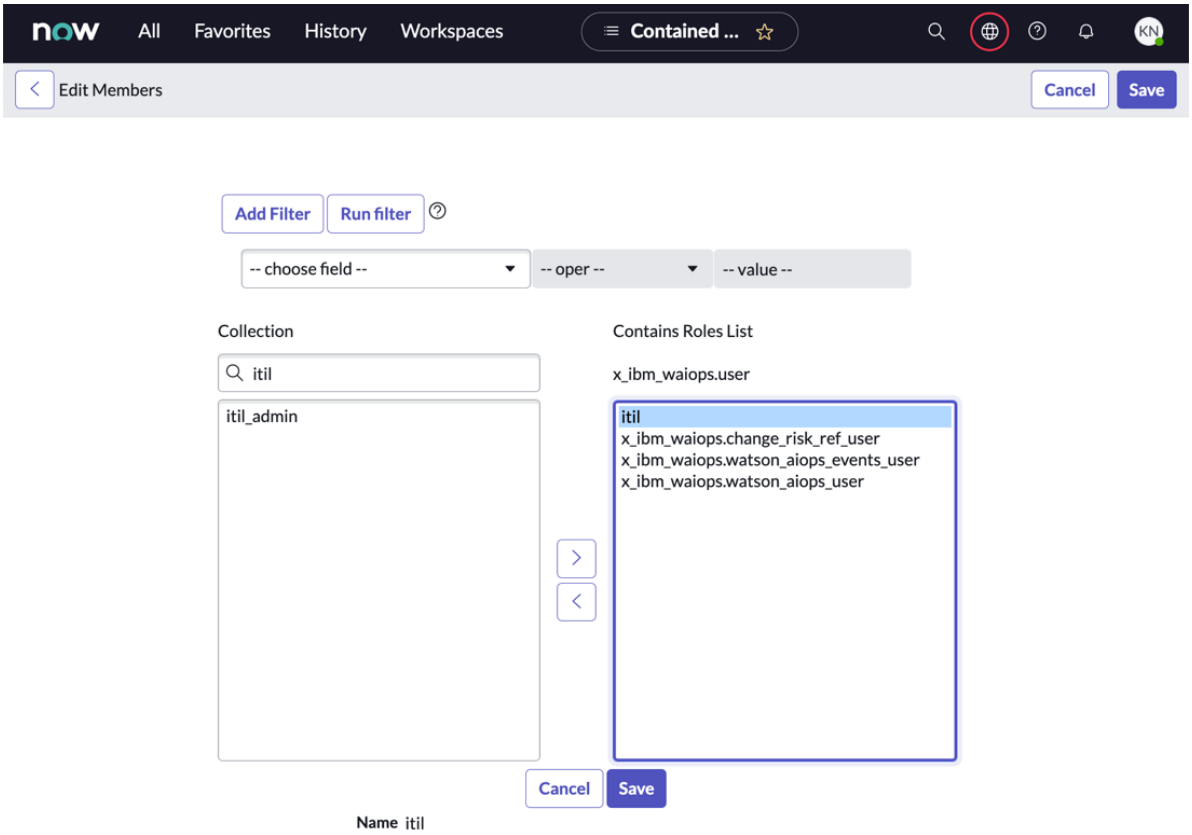

Figure. ServiceNow roles list

User roles

1. Go to **Organization** > **Users**. Create at least 2 users, an admin and a generic user to be a Site Reliability Engineer (SRE).
   - For an admin user, provide values for admin's user ID and admin's first name fields. For example, the admin's user ID can be be **`ibm.aiops`**, and the admin's first name can be **`IBM Cloud Pak for AIOps`**.
   - For the SRE user, specify values for the user ID, first, and last name.
2. For each user, set up a password by clicking **Set Password**. After you click **Set Password**, ServiceNow assigns a default password.
3. Copy and save the password. The first time that you log in with the default password, ServiceNow prompts you to set a new password. Make sure to change the default password.
4. For each user, find the **Roles** tab.

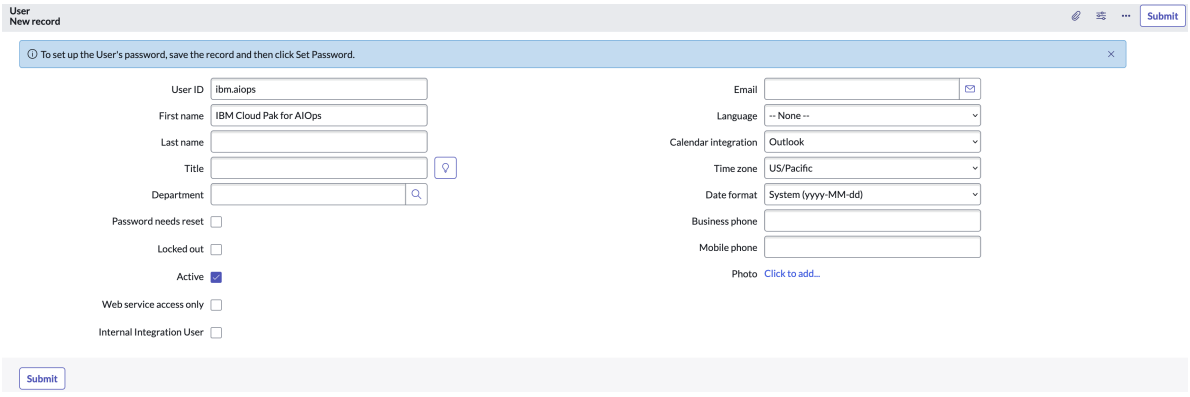

Figure. ServiceNow user creation

5. For the admin user, assign the **`x_ibm_waiops.admin`** role to be used in step 6 of Creating a ServiceNow integration.

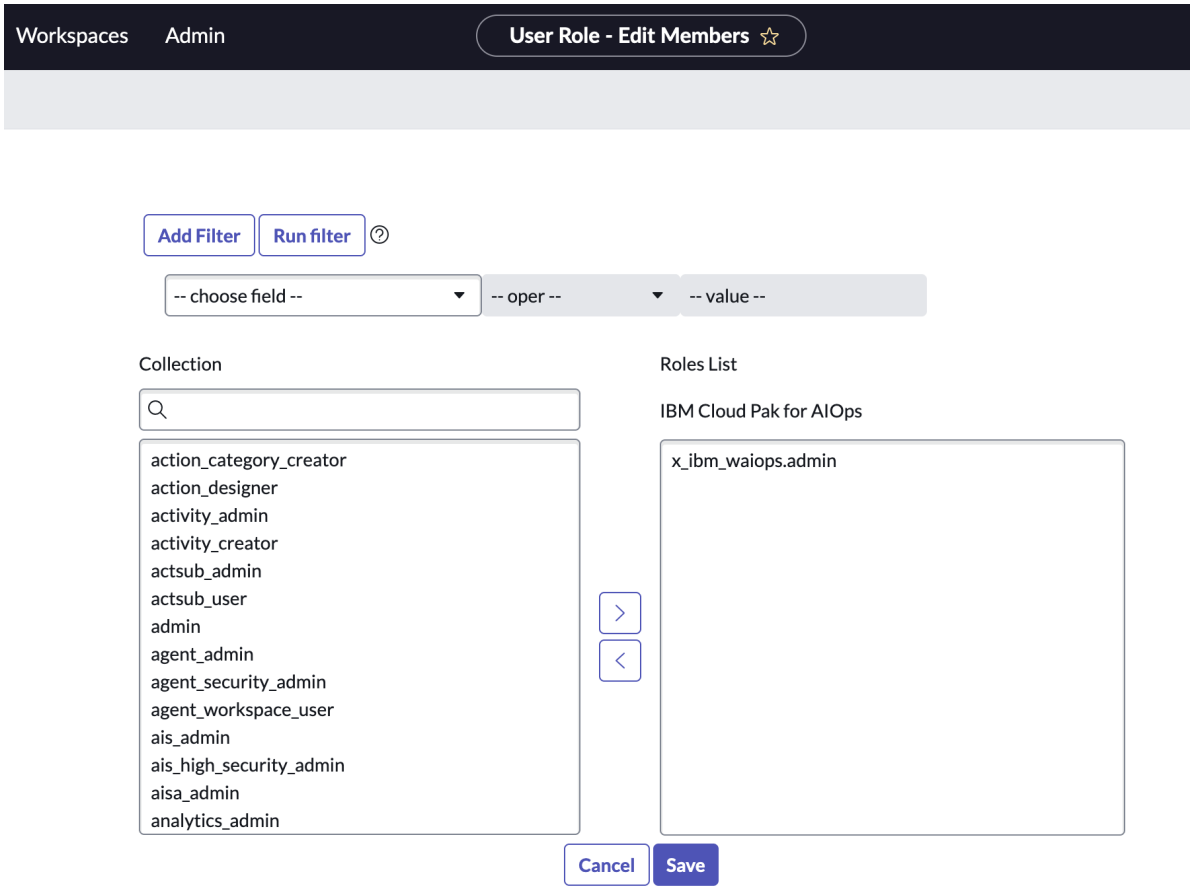

Figure. ServiceNow role assignment

This admin user will have their name, **`IBM Cloud Pak for AIOps`**, attached to the generated incidents and change ticket assessments that are created by IBM Cloud Pak for AIOps in ServiceNow.

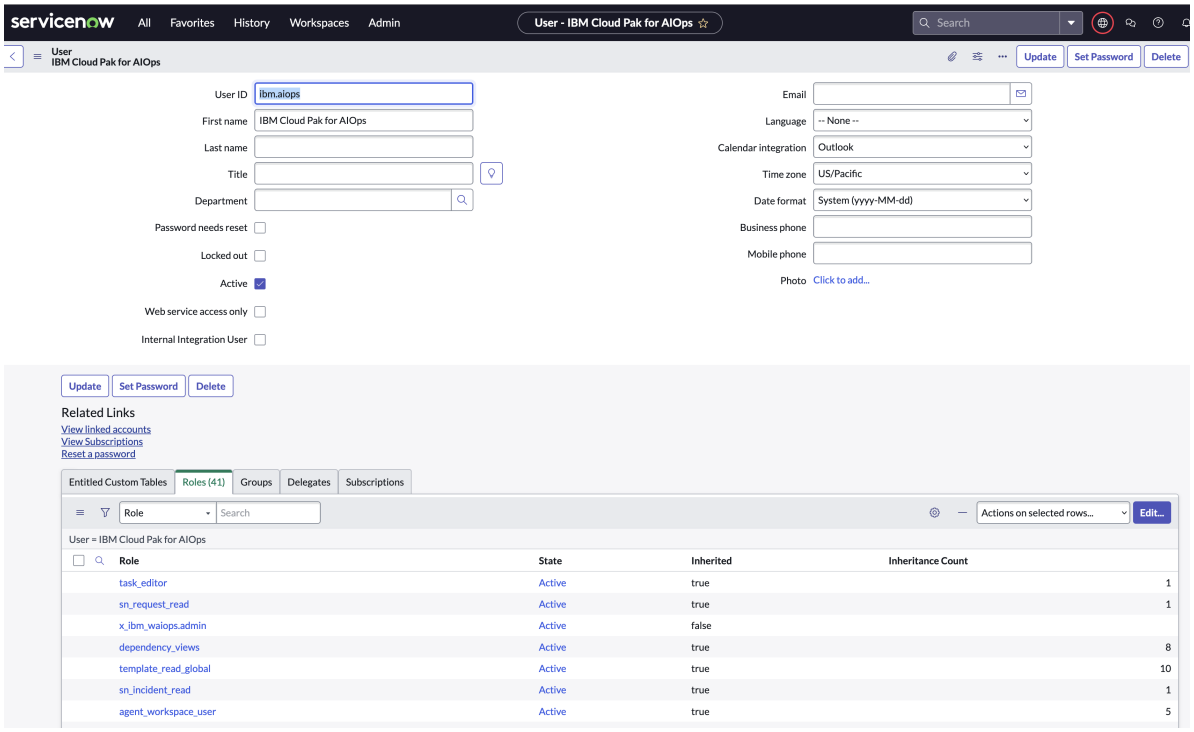

Figure. ServiceNow user roles

6. For the SRE user, assign the **`x_ibm_waiops.user`** role so that the user can view and assess ServiceNow incidents and change tickets.

Important:

- Make sure that the time zone of your *admin user* (the user value that is used to create your ServiceNow integration) matches your system time zone in ServiceNow. If the two values are not synchronized, the flow of your change request data from ServiceNow to IBM Cloud Pak for AIOps can be disrupted.

- To view the details provided by the ServiceNow integration, switch to the **IBM Cloud Pak for AIOps** view as shown in the following image:

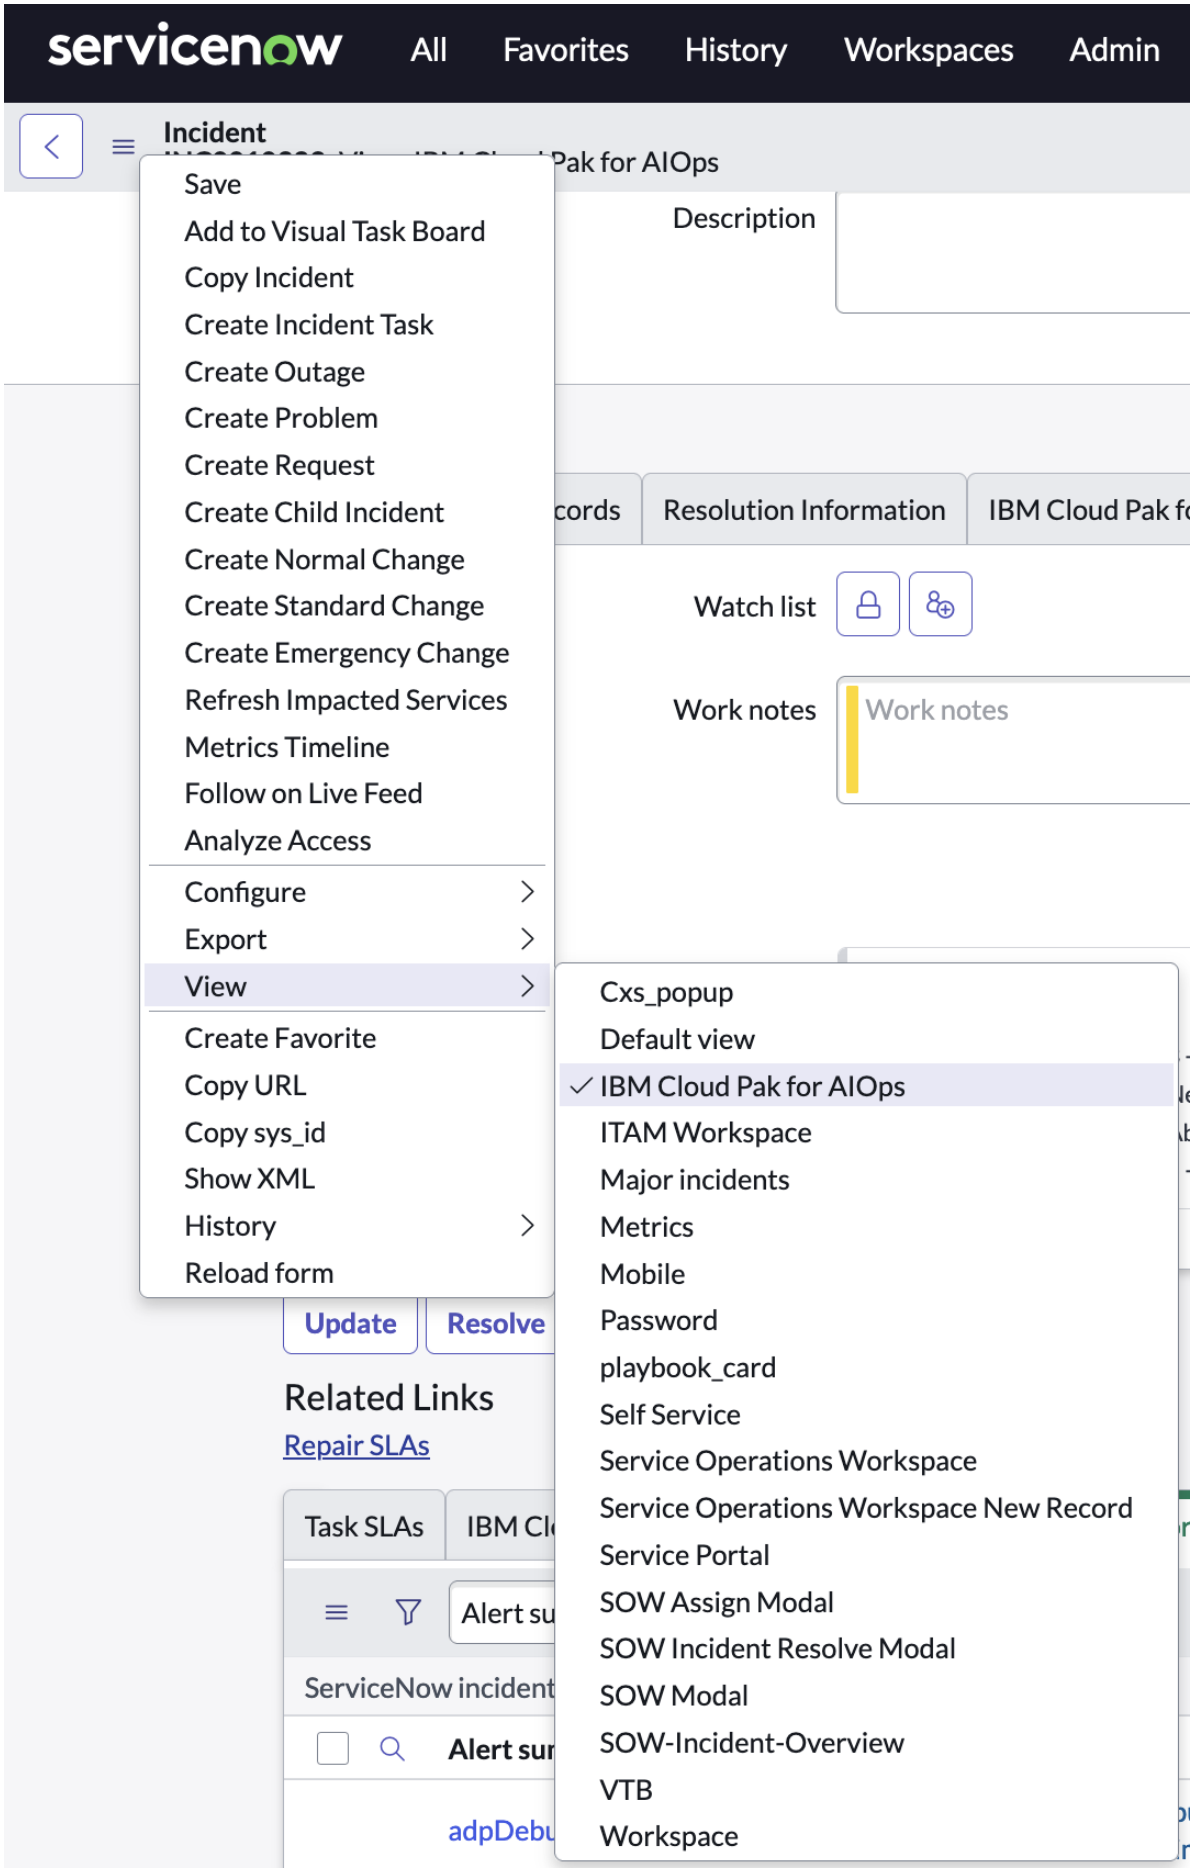

Figure. Cloud Pak View for ServiceNow integration

Create the ServiceNow integration

You also need the ServiceNow integration to be created with the IBM Cloud Pak for AIOps UI. For more information, see Creating a ServiceNow integration.

ServiceNow App configuration page

Although the **System properties for integration with IBM Cloud Pak for AIOps** page is still visible in the ServiceNow App, you do not need to configure it.

Creating a Change Risk Assessment

Complete the following steps to create and view a change request.

1. Within the IBM Cloud Pak® for AIOps WebUI, make sure ServiceNow Integration is set to the *Live data for continuous ticket data collection* mode. For more information, see step 11 of Creating a ServiceNow integration.
2. You also need a ServiceNow integration and a trained and deployed Change Risk model. For more information, see Training a Change Risk model.
3. Within your ServiceNow instance, go to **Change** > **All** to view all existing change requests.
4. Click **New** > **Create Normal Change**. Add a short description for your change. Then, click **Submit**. If ServiceNow sends you to another page, select **Change** > **All** and find the change ticket that you created.

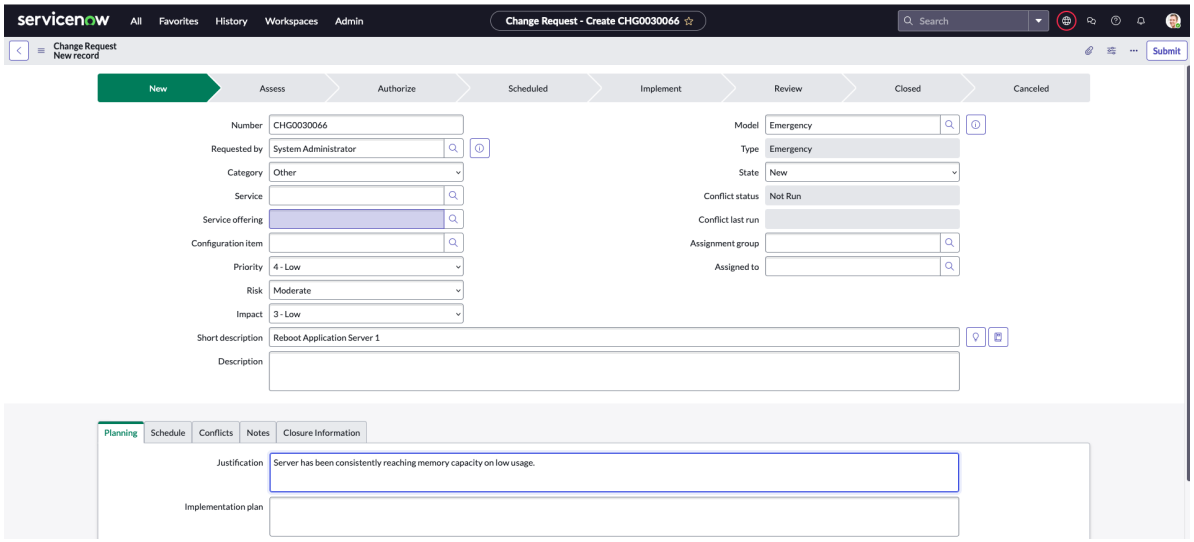

Figure. Change request short description

5. View the Change Request and the Change Risk Assessment tab.

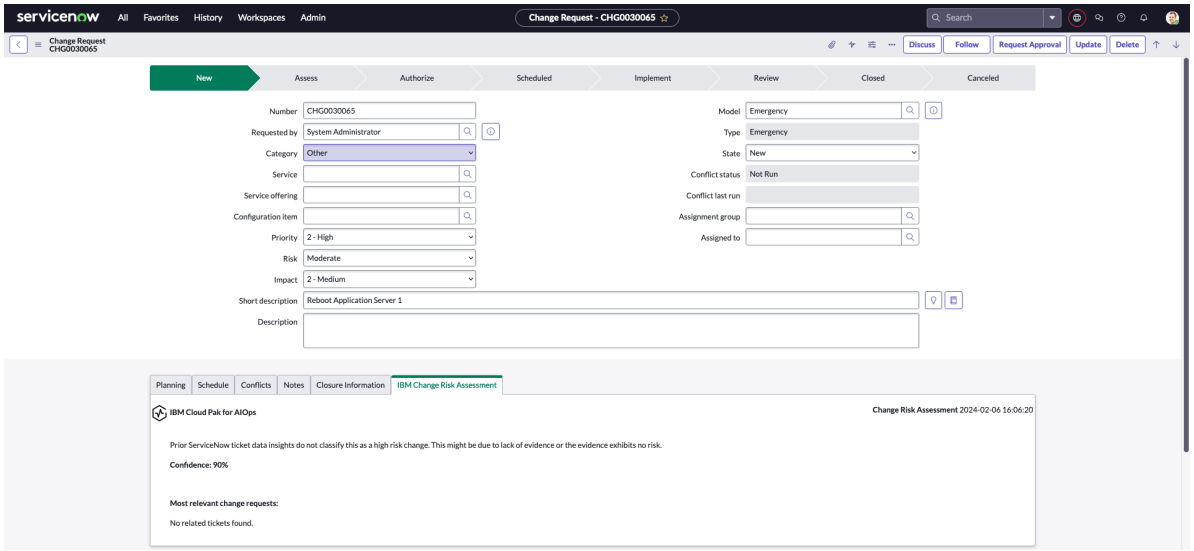

Figure. Change Request Assessment tab

ServiceNow App privacy policy

The IBM Cloud Pak for AIOps ServiceNow integration optionally collects and stores data only when the data collection is enabled. Otherwise, only the references to created records are stored in ServiceNow.

Data collection, historical data, and live data can all be enabled or disabled in the IBM Cloud Pak for AIOps ServiceNow integration UI.

Data collection and usage

Note: No data is shared with the third parties.

In ServiceNow integration the following data is collected upon enabling:

- If **historical data** is enabled, ServiceNow incident and change request records are collected and stored for AI model training with a one-time poll. Records can be excluded from the poll by specifying which ticket types need to be collected.
- If **live data** is enabled, data is collected and stored at a configurable polling interval:
- **Add risk assessments to new ServiceNow change tickets**: Change request records are collected and stored to be used for AI model training.
- **Update alerts in Cloud Pak for AIOps when corresponding incident-based alerts are updated in ServiceNow**: Alert records in ServiceNow are polled at the set interval for changes. If a relevant update exists, an alert record is sent back to IBM Cloud Pak for AIOps, and the record is not stored. For alerts, relevant updates include changes to summary, severity, state, event count, and last occurrence values.
- **Update incidents in Cloud Pak for AIOps when corresponding incident is updated in ServiceNow**: Incident records in ServiceNow are polled for changes at the set interval. If a relevant update exists, an incident record is sent back to IBM Cloud Pak for AIOps, and the record is not stored. For incidents, relevant updates include changes to title, description, state, and priority values.
- **Collect resolved ServiceNow incidents for similar tickets training**: Incident records are collected at the set interval, which is stored for AI model training, and for the similar incidents algorithm.

ServiceNow data security and management

ServiceNow data is transferred by using HTTPS protocol. The data is stored in enterprise databases, and secured within the OpenShift environment.

Note: You are responsible for the security of the IBM Cloud Pak for AIOps deployment, which includes the ServiceNow data.

Creating an SSH integration

An SSH integration provides an integration to the system where scripts and command can be run. The integration is agentless and connects directly to the target machine. It authenticates by using SSH public key authentication.

The SSH provider works for back-end systems (targets) running UNIX or Windows. For UNIX, the user running the automation must have sufficient rights to run these features.

- `bash` - A shell that is used to wrap and run the specified commands or script.
- `mktemp` - A utility that is used to create a temporary file, which is required for the script execution with this automation provider to work.
- `openssl` - A utility that is used on the target system to decrypt the transferred commands or script.

Note: You can only create one SSH integration. Also, you must have an account with administrator role to create, edit, view, or delete an SSH integration.

Before configuring you need to provide the following information:

- General integration information

If you are using a jump server (optional), you must configure it. Depending on your environment, you might require a jump server to access your target endpoints. A jump server is an SSH endpoint that is used to connect to the nested SSH endpoints. This is a common approach that is used to communicate between different network zones. To use a jump server with RBA, it must have an SSH server that is running and the `nc` command must be available. This is used to connect to nested SSH target endpoints.

Jump server configuration information:

- **Host name/IP Address:** The hostname or IP address of the jump server.
- **Port Number:** The SSH port of the jump server.
- **Username:** The username for authentication on the jump server.
- **Password:** The password for authentication on the jump server.

Figure. Create SSH integration

Any integrations to SSH target endpoints use the specified jump server.

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating an SSH integration

To create an SSH integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **SSH** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On your target machine, register the default public key to enable access to the target endpoints through SSH for all users.

   Configuring SSH public key authentication for the UNIX root user

   The displayed public key must be added to all target machines that you plan to run scripts on through the SSH Provider. This key enables any RBA user to run script automations on the given target endpoint. The key must be added to the authorized_keys file that is usually found in the /root/.ssh/authorized_keys folder.

   Configuring SSH public key authentication for a specific UNIX user

   If you want to enforce that only a specific UNIX user can run the script on this target endpoint you should copy the key to the authorized_keys file in the home directory of the specific user, for example /home/john/.ssh/authorized_keys.

   You can regenerate the public key by clicking the **refresh** button in the upper right corner of the public key.

   Note: Regenerating the public key deletes the old key pair. If you choose to regenerate the key pair, you must exchange the public key in each target machine that you plan to access through the SSH Provider.
7. On the *Manage SSH Keys* tab that opens, you will see the SSH field default public key for SSH. You need to click the **Copy SSH key** symbol to copy this key to each target system, and append it to the authorized_keys file, for example ~/.ssh/authorized_keys.

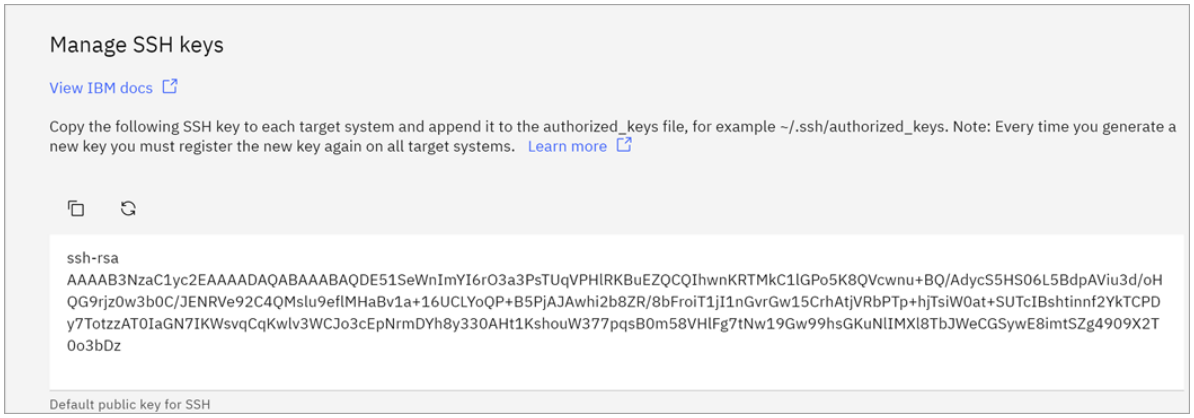

Figure. Manage SSH keys

An example of an SSH key is:

```
ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAABAQDuZkPxIyYH9NrfLEBkIGdwc6frF7WgR9vKZavE97GlTfAAZVhqoTsXO2jLo28sNC7+8wkOYnFEdfBff9tcQPx/
lc3d1df35/hJIT0a3jeHxw8YrU3/y6QIzynVvSgcQfKzB33wdN7n8xC5ZPWKXEWM7FbP58kOdzHw7f8fbBIKlPRc9SOUrC0JGvndVvpHOU7x8S3q9EJ1
D2nKaozA6yu2mcH38CLTNCBRRwbPZ+rxBxWdvJ4mMWvWtJe4lt50W2zAGCIscLKLbyyMGp/DCcJFsMhkOetBDuxAfL1ZkO7rXPT5vK5Fp6549OPDXjqf
HKEJ+9WASZD2ui1qmCdeQpUN
```

Note: Every time that you generate a new key that you must register the new key again on all target systems.

8. Click **Next**.
9. The *Define a jumpserver (Optional)* tab opens. Set the *Enable jumpserver* toggle to 'On' if you want to provide this information. The following fields show:
   - **Host name or IP address:** The hostname or IP address of the jump server.
   - **Port Number:** The SSH port of the jump server.
   - **User ID:** The username for authentication on the jump server.
   - **Password:** The Password for authentication on the jump server.
10. Click **Done**.

Editing an SSH integration

After you create your integration, your can edit the integration. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **SSH** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the SSH integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration. Click **Next** to go through the integration configurationn pages. Click **Save** when you are done editing.

Deleting an SSH integration

If you no longer need your SSH integration and want to delete it entirely, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **SSH** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the SSH integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Installing new SSH key during migration

The SSH key that is associated with an SSH integration cannot be moved or copied to another deployment.

When you migrate from one deployment where you set up an SSH integration (for example, from an installation of IBM Netcool Operations Insight, or from a test installation of IBM Cloud Pak® for AIOps) to a new deployment (for example, to an installation of IBM Cloud Pak® for AIOps), then you must set up an SSH integration in the new deployment as well. This SSH integration creates its own SSH key.

Say you have installed the SSH key of the original deployment on some target systems. Now, you want to run the same SSH actions (that you migrated to the new deployment as part of the enclosing runbooks) against the same set of target systems again. You must first install the new SSH key to each of those target systems. One way of performing this administrative action is by using the sample runbooks as described in this topic.

The following procedure uses two fully automated runbooks that are delivered as sample runbooks:

- Example: Add new SSH key to target systems
- Example: Remove old SSH key from target systems

These sample runbooks have been added beginning with IBM Netcool Operations Insight 1.6.11 and IBM Cloud Pak® for AIOps 4.3.0. If the version of your original deployment does not yet contain these sample runbooks, you can import them to your original deployment. The original deployment must be at least at version IBM Netcool Operations Insight 1.6.6 or IBM Cloud Pak® for AIOps 3.5. For general instructions on exporting and importing runbooks, see Export and import runbooks.

1. Copy each of the two sample runbooks into your own new runbooks in the new deployment.
2. Export those copies of the sample runbooks from the new deployment.
3. Edit the exported JSON files and remove the `tags` property from within the `exportedAutomation` object.
4. Import the two runbooks into the original deployment.

Note:

- The scripts that are included in the actions within these runbooks require the `bash` shell to be installed on each of the target systems. If some of your target systems do not support `bash` then you need to create your own copy of the sample runbooks and their nested actions and adjust the scripts to run with `sh` only. To do this, you must modify or remove the conditional statement that uses a regular expression to do a smoke test on the SSH key.
- The scripts create a backup file of the authorized keys file that they are about to modify (for example, `authorized_keys.rbaBeforeAdd.bak` and `authorized_keys.rbaBeforeRemove.bak`).
- The two sample runbooks support Linux target systems only. You can use them as blueprints to create your own variants for target systems that use Windows Powershell.
- The two sample runbooks must be published to be executable by using the API.

Part 1: Add the new SSH key to all target systems

To get familiar with the sample runbook "Example: Add new SSH key to target systems" or if you have only a few target systems, then you can run the sample runbook from the UI of the original deployment. Each of the runbook parameters includes a description of what to specify and which format to use.

If you have many targets, then you can use the following description to define a batch of up to about 100 target hostnames and invoke the runbook by using the runbook API to add the new SSH key to each of those targets.

You must perform this part by using the original deployment ("`OLD_INSTALL`"), which has its SSH key that is already installed on all target systems. You can run the commands from any environment that has network access to your original deployment.

- **If the original deployment is IBM Cloud Pak® for AIOps**
  - Set the value of the `CURL_BASEURL_OLD_INSTALL` variable to the IBM Cloud Pak® for AIOps user interface URL and replace the path with "`/aiops/api/story-manager/rba/v1`". The following example assumes that the URL is "`https://cpd-cp4waiops.apps.mycluster.mycompany.com/zen/#/homepage`".
  - To set the value of the `CURL_AUTH_TOKEN_OLD_INSTALL` variable you must have an API key created first. If you need to generate an API key, follow the instructions in Generating API keys for authentication. The `<username>` in the command that follows is the user ID that you used to log in to the IBM Cloud Pak® for AIOps user interface when generating the API key.
  - Use `CURL_OPTIONS_OLD_INSTALL` to specify any options that you need to use for the curl command itself. For example, use "`-k`" to allow insecure SSL connections if you have not installed the deployment's certificate yet.

    ```
    export CURL_BASEURL_OLD_INSTALL="https://cpd-cp4waiops.apps.mycluster.mycompany.com/aiops/api/story-manager/rba/v1"
    export CURL_AUTH_TOKEN_OLD_INSTALL=`echo -n "<username>:<api_key_value>" | base64 -w 0`
    export CURL_AUTH_METHOD_OLD_INSTALL="ZenApiKey"
    export CURL_OPTIONS_OLD_INSTALL="-k"
    ```

- **If the original deployment is IBM Netcool Operations Insight**
  - Set the value of the `CURL_BASEURL_OLD_INSTALL` variable to the hostname where the IBM Netcool Operations Insight service is running, prefix it with "`https://`" and append "`/api/v1/rba`". For example, `https://netcool.apps.mycluster.mycompany.com/api/v1/rba`.
  - To set the value of the `CURL_AUTH_TOKEN_OLD_INSTALL` variable you must have an API key created first. If you need to generate an API key, follow the instructions in API Keys.
  - Use `CURL_OPTIONS_OLD_INSTALL` to specify any options that you need to use for the curl command itself. For example, use "`-k`" to allow insecure SSL connections if you have not installed the deployment's certificate yet.

    ```
    export CURL_BASEURL_OLD_INSTALL="https://netcool.apps.mycluster.mycompany.com/api/v1/rba"
    export CURL_AUTH_TOKEN_OLD_INSTALL=`echo -n "<api_key_name>:<api_key_password>" | base64 -w 0`
    export CURL_AUTH_METHOD_OLD_INSTALL="Basic"
    export CURL_OPTIONS_OLD_INSTALL="-k"
    ```

- **Common for all deployment types**

  Run the following command to verify the base URL and the authentication token:

  ```
  curl -X GET ${CURL_OPTIONS_OLD_INSTALL} -H "Authorization: ${CURL_AUTH_METHOD_OLD_INSTALL} ${CURL_AUTH_TOKEN_OLD_INSTALL}" "${CURL_BASEURL_OLD_INSTALL}/status"
  ```

The previous command is expected to produce some informational data about the speed of the transfer and some JSON result data similar to the following:

```
{"rbs":0,"as":0,"db":0,"connection":{"AWX":0,"IMPACT":2,"SCRIPT":0,"GITHUB":0},"errors":[],"warnings":[]}
```

Note: Some of the connection items might have a different value than "0", and the "errors" array within the JSON result data might be nonempty (if the connection is in a failed state) - this is not a problem in this context.

The values for the following set of variables must be defined as outlined here:

- `RUNBOOK_ID_ADD_SSH_KEY`: The runbook ID of the sample runbook **Example: Add new SSH key to target systems** in the original deployment.
- `PARAM_TARGET_HOSTNAMES`: A stringified array of hostnames, which defines the batch of target systems to be updated in this iteration.
- `PARAM_TARGET_USER`: The user id to be used on the target system. This user id is the same for all target systems in the batch. If different user ids need to be used, then the batches of target hostnames need to be split accordingly.
- `PARAM_AUTHORIZED_KEYS_FILE_PATH`: The relative path to the authorized keys file within the target user's home directory, or an absolute path. You can use an arbitrary file name to test the tooling (but the file needs to exist on the target). Defaults to ".ssh/authorized_keys".
- `PARAM_NEW_SSH_KEY`: The complete SSH key as copied from the SSH integration of the new deployment.
- `PARAM_OPTIONS`: Optional options for the SSH key. Must conform to the SSH specification (not validated by the tooling). Make sure to escape double quotes (see example below).
- `PARAM_COMMENT`: The comment to be saved along with `PARAM_NEW_SSH_KEY` in the `authorized_keys` file on the target systems. Must conform to the SSH specification (not validated by the tooling). Defaults to "RunbookAutomation".
- `PARAM_VERBOSE`: Set this to `true` to create verbose output for each of the editing actions on the target systems. Set this to `false` to just get a `successful` or `failed` result for the editing actions on the target systems.
- `PARAMETER_ADD_FILE_PATH`: Name of the temporary file that gets generated to contain the parameters in JSON format.

For example:

```
export RUNBOOK_ID_ADD_SSH_KEY="2f2ba8ee-4ee6-4a36-b213-2be5ec65249f"

export PARAM_RAW_TARGETS="doesnotexist1.myzone.mycompany.com"
export PARAM_RAW_TARGETS=${PARAM_RAW_TARGETS}`for i in {2..100}; do echo -n
",doesnotexist${i}.myzone.mycompany.com"; done`
export PARAM_TARGET_HOSTNAMES="[${PARAM_RAW_TARGETS}]"
export PARAM_TARGET_USER="root"
export PARAM_AUTHORIZED_KEYS_FILE_PATH=".ssh/authorized_keys_test"
export PARAM_NEW_SSH_KEY="ssh-rsa
testtesttesttestt
```

```
# Failed, reason: target system not found
doesnotexist1.myzone.mycompany.com error: Connection to target via TCP unsuccessful.
doesnotexist1.myzone.mycompany.com status: failed
```

If you have more than about 100 targets and you want to get all of your targets updated, then you must split your total list of targets into batches, and run the runbook for each batch. If you choose to write a script that loops over the set of batches, make sure to add some sleep time after you have started a batch, so the Runbook Automation service can finish the work in the background. Once you have run a few batches, you can review the actual execution time for each of them in the runbook activities view, so you can adjust the sleep time (for example, allow 30 seconds per batch).

Part 2: (Optional) Validate the new SSH key and remove the old SSH key from all target systems

You must perform this part by using the new deployment, which by now (as per part 1) has its SSH key installed on all target systems. The following steps can also be used to verify that the new key works.

Warning: Run the following steps only when the original deployment is no longer intended to run any actions on the target systems.

To get familiar with the sample runbook "Example: Remove old SSH key from target systems" or if you have only a few target systems, then you can run the sample runbook from the UI of the new deployment. Each of the runbook parameters includes a description of what to specify and which format to use.

If you want to use the runbook API to invoke the runbook, then you can run the following commands from any environment that has network access to your new deployment ("`NEW_INSTALL`").

The same comments on creating batches of target systems from part 1 apply to this part.

- The values for the following set of variables must be defined as outlined here:
  - `CURL_BASEURL_NEW_INSTALL`: Set analogously to `CURL_BASEURL_OLD_INSTALL` from part 1.
  - `CURL_AUTH_TOKEN_NEW_INSTALL`: Set analogously to `CURL_AUTH_TOKEN_OLD_INSTALL` from part 1.
  - `CURL_AUTH_METHOD_NEW_INSTALL`: Set analogously to `CURL_AUTH_METHOD_OLD_INSTALL` from part 1.
  - `CURL_OPTIONS_NEW_INSTALL`: Set analogously to `CURL_OPTIONS_OLD_INSTALL` from part 1.
  - `RUNBOOK_ID_REMOVE_SSH_KEY`: The runbook ID of the sample runbook **Example: Remove old SSH key from target systems** in the new deployment.
  - `PARAM_TARGET_HOSTNAMES`: See part 1.
  - `PARAM_TARGET_USER`: See part 1.
  - `PARAM_AUTHORIZED_KEYS_FILE_PATH`: See part 1.
  - `PARAM_OLD_SSH_KEY`: The complete SSH key as copied from the SSH integration of the old deployment.
  - `PARAM_VERBOSE`: See part 1.
  - `PARAMETER_REMOVE_FILE_PATH`: Name of the temporary file that gets generated to contain the parameters in JSON format.

  For example:

```
# If new deployment is an IBM Cloud Pak for AIOps installation
export CURL_BASEURL_NEW_INSTALL="https://cpd-cp4waiops.apps.mycluster.mycompany.com/aiops/api/story-manager/rba/v1"
export CURL_AUTH_TOKEN_NEW_INSTALL=`echo -n "<username>:<api_key_value>" | base64 -w 0`
export CURL_AUTH_METHOD_NEW_INSTALL="ZenApiKey"
export CURL_OPTIONS_NEW_INSTALL="-k"

# If new deployment is an IBM Netcool Operations Insight installation
export CURL_BASEURL_NEW_INSTALL="https://netcool.apps.mycluster.mycompany.com/api/v1/rba"
export CURL_AUTH_TOKEN_NEW_INSTALL=`echo -n "<username>:<api_key_value>" | base64 -w 0`
export CURL_AUTH_METHOD_NEW_INSTALL="Basic"
export CURL_OPTIONS_NEW_INSTALL="-k"

# Verify that the new installation can be reached
curl -X GET ${CURL_OPTIONS_NEW_INSTALL} -H "Authorization: ${CURL_AUTH_METHOD_NEW_INSTALL}
${CURL_AUTH_TOKEN_NEW_INSTALL}" "${CURL_BASEURL_NEW_INSTALL}/status"

# Set other environment variables
export RUNBOOK_ID_REMOVE_SSH_KEY="50fc56e5-55a9-429d-8c1e-7f0c59f0557f"

export PARAM_RAW_TARGETS="doesnotexist1.myzone.mycompany.com"
export PARAM_RAW_TARGETS=${PARAM_RAW_TARGETS}`for i in {2..100}; do echo -n
",doesnotexist${i}.myzone.mycompany.com"; done`
export PARAM_TARGET_HOSTNAMES="[${PARAM_RAW_TARGETS}]"
export PARAM_TARGET_USER="root"
export PARAM_AUTHORIZED_KEYS_FILE_PATH=".ssh/authorized_keys_test"
export PARAM_OLD_SSH_KEY="ssh-rsa
testtesttesttestt
```

```
curl -X POST ${CURL_OPTIONS_NEW_INSTALL} -s -H "Authorization: ${CURL_AUTH_METHOD_NEW_INSTALL}
${CURL_AUTH_TOKEN_NEW_INSTALL}" -H "Expect:" -H "Content-Type: application/json; charset=utf-8" -d
@${PARAMETER_REMOVE_FILE_PATH} "${CURL_BASEURL_NEW_INSTALL}/runbooks/${RUNBOOK_ID_REMOVE_SSH_KEY}/execute"
```

SSH algorithms

SSH actions can connect to SSH servers configured with the following algorithms.

Table. SSH algorithms

Ciphers	Compression algorithms	MAC algorithms	Key exchange algorithms	Server host key formats
`chacha20-poly1305@openssh.com` (not available when cluster is FIPS enabled)	`none`	`hmac-sha2-256-etm@openssh.com`	`curve25519-sha256` (not available when cluster is FIPS enabled)	`ssh-ed25519` (not available when cluster is FIPS enabled)
`aes128-gcm@openssh.com`	`zlib@openssh.com`	`hmac-sha2-512-etm@openssh.com`	`curve25519-sha256@libssh.org` (not available when cluster is FIPS enabled)	`ecdsa-sha2-nistp256`
`aes256-gcm@openssh.com`	`zlib`	`hmac-sha1-etm@openssh.com` (not available when cluster is FIPS enabled)	`ecdh-sha2-nistp256`	`ecdsa-sha2-nistp384`
`aes128-ctr` (not available when cluster is FIPS enabled)		`hmac-sha2-256`	`ecdh-sha2-nistp384`	`ecdsa-sha2-nistp521`
`aes192-ctr` (not available when cluster is FIPS enabled)		`hmac-sha2-512`	`ecdh-sha2-nistp521`	`rsa-sha2-512`
`aes256-ctr` (not available when cluster is FIPS enabled)		`hmac-sha1` (not available when cluster is FIPS enabled)	`diffie-hellman-group-exchange-sha256` (not available when cluster is FIPS enabled)	`rsa-sha2-256`
			diffie-hellman-group14-sha256	`ssh-rsa` (not available when cluster is FIPS enabled)
			diffie-hellman-group15-sha512	
			diffie-hellman-group16-sha512	
			diffie-hellman-group17-sha512	
			diffie-hellman-group18-sha512	

Creating email notification integrations

Use email notification integrations to send custom email messages when incidents are created and closed. Once an email notification integration is set up and running, you can select it from the Notifications area of your Promote alerts to an incident policies.

- About this task
- Prerequisites
- Fields available for inclusion in custom emails
- Creating an email integration
- Editing an email integration
- Deleting an email integration

About this task

Create one or more integrations by defining the integration details that are outlined here. You must provide a source email address (to send the incident notifications from) and the email addresses of recipients. Also, specify what incident details are sent in an email when incidents are created and closed. A default template is provided.

Prerequisites

You need the following information to create an email notification integration:

- Hostname or IP address of your SMTP server
- Port of your SMTP server
- Source (sender) email address
- SMTP username (optional)
- SMTP credentials for source email address (optional)
- Email addresses of the intended recipients
- Use of TLS to encrypt email

Note: Email notification integration supports the Simple Mail Transfer Protocol (SMTP) authentication with email addresses or with optional **SMTP username**. This approach ensures seamless integration with a wide range of email services.

Amazon Simple Email Service (SES) is supported with email notification integration. You need to use your AWS region SMTP server for example, **`email-smtp.us-east-1.amazonaws.com`**. You need to use a secure port, not 25, for example, 587. The **`Source email address`** needs to be a verified email address in your AWS SES account. The **`SMTP username`** and **`SMTP password`** fields are mandatory if they are required by Amazon SES SMTP server.

For more information about how to obtain SES SMTP credentials, see Obtaining Amazon SES SMTP credentials.

For more information about requirements to send email over SMTP by using SES, see Requirements to send email over SMTP.

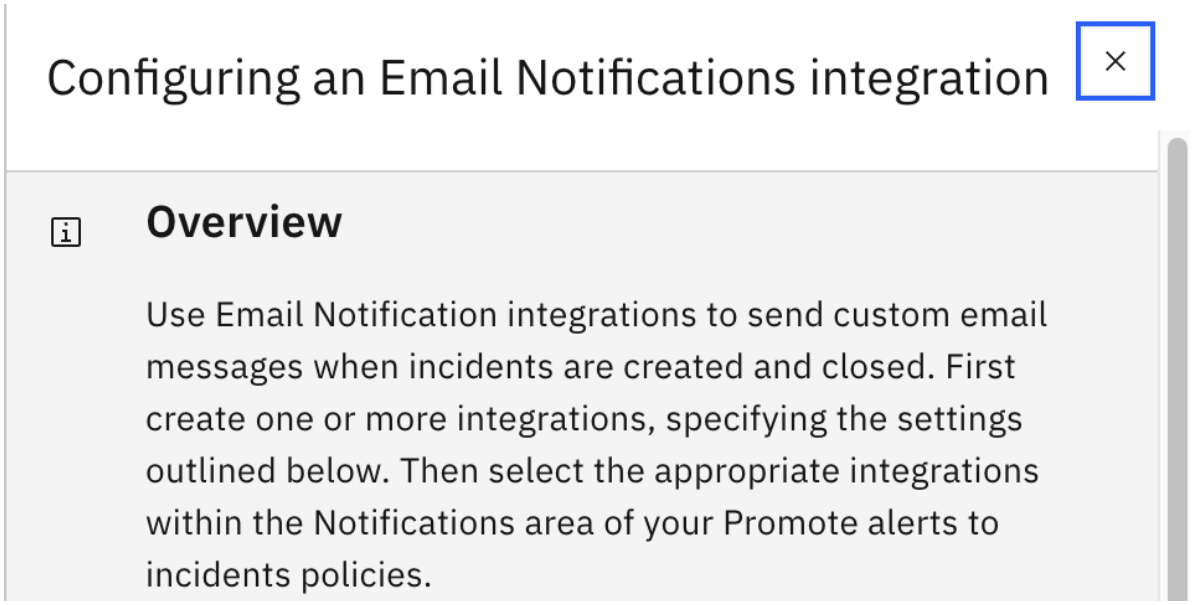
Fields available for inclusion in custom emails

The following dynamic fields are availble for you to include in custom emails:

Field	Type	Description
`id`	string	A unique identifier for the incident.
`createdTime`	string	Time at which the incident was created.
`createdBy`	string	Person who created the incident.
`title`	string	Short description of the incident.
`description`	string	Longer description of the incident.
`langId`	string	ISO 639-3 language ID.
`priority`	integer	Indication of the relative impact of the issue that caused this incident to be raised.
`state`	string	The current state of the incident.
`lastChangedTime`	string	The time at which the incident last changed.
`owner`	string	The owner assigned to the incident.
`team`	string	The team assigned to the incident.
`alertIds`	array	The set of related alert id's that have triggered the creation of the incident. These alerts affect and are affected by the lifecycle of the incident. The incident will only be automatically resolved if all of the alerts are cleared. When the incident is resolved all of these alerts will be cleared.
`contextualAlertIds`	array	The set of alert id's that provide additional context to the incident due to relationships with the triggering alerts or other contextual alerts. These alerts do not affect or are affected by the lifecycle of the incident.
`insights`	array	An array of insights associated with the incident with one or more other entities or groupings.

To include a dynamic field, use the following syntax:

```
$string(incident.<field_name>)
```



For example, if you want to include the time at which the incident was created, include the following code in the email template:

```
$string(incident.createdTime)
```

Creating an email integration

To create an email integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Email Notifications** tile.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.

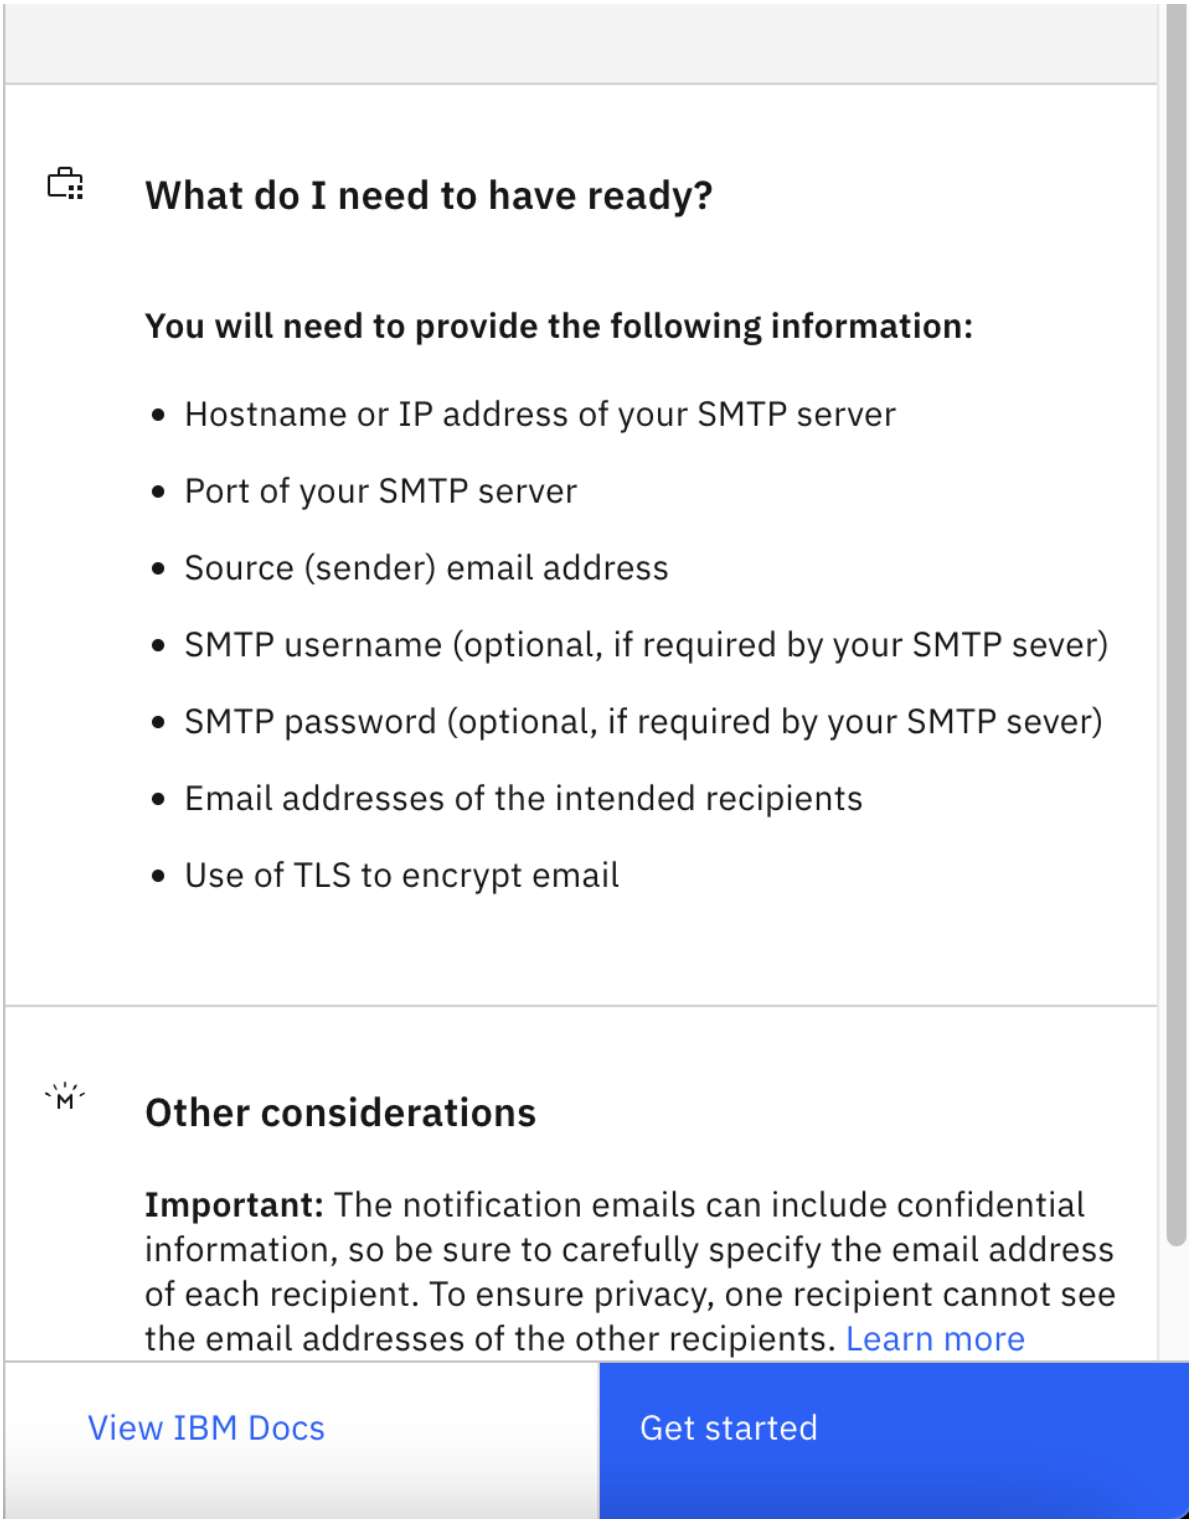


Figure. Configure Email Notifications integration

6. On the *Add integration* page, define the general integration details:

- **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
- **Description** (optional): Optionally, enter a description of the integration.
- **Hostname or IP address of SMTP server**: Enter the hostname or IP address of the SMTP server. **Note**: If running behind a proxy server, enter the proxy server hostname or IP address.
- **Port of SMTP server**: Enter the port of the SMTP server.

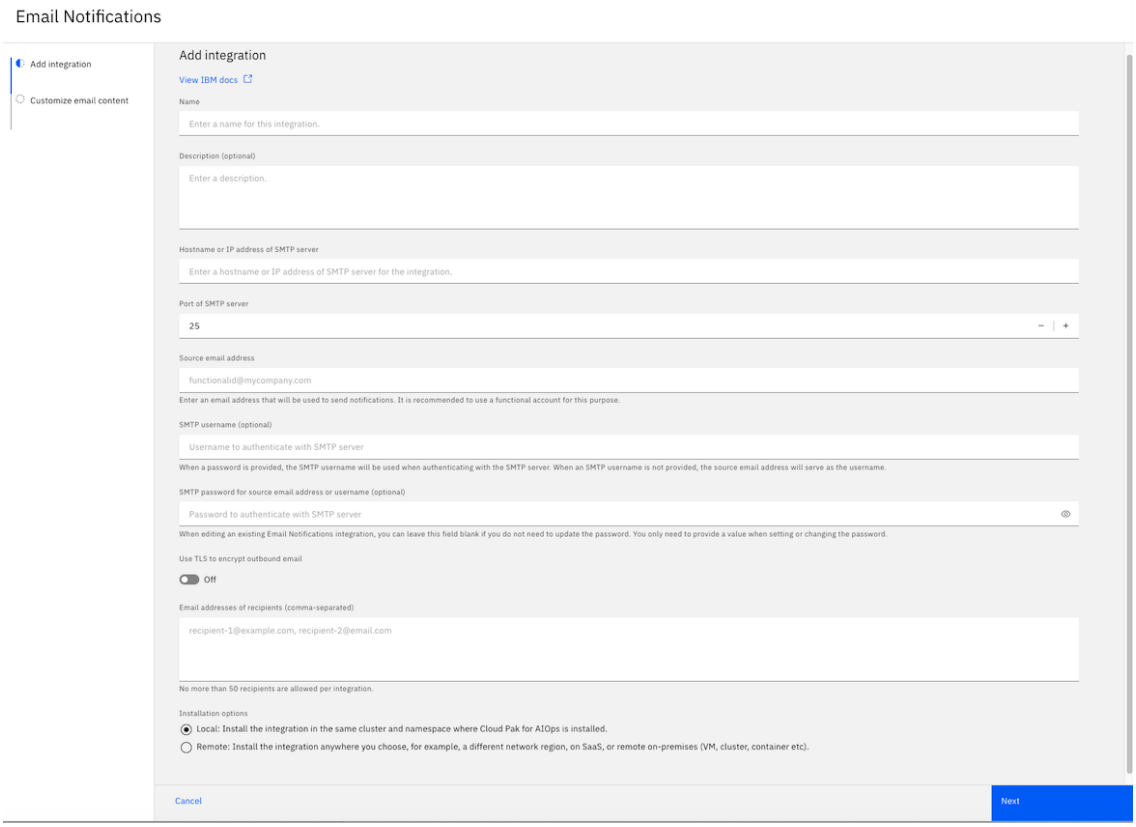

Figure. Add Email Notifications integration

- **Source email address**: The email address that the new incident notifications will be sent from. It is recommended to use a functional email account for this purpose.
- **SMTP username (optional)**: Enter the SMTP username. When a SMTP username is not provided, the source email address is used as the username.
- **SMTP password for source email address** (optional): Optionally, enter an SMTP password for the source email address.
- **Use TLS to encrypt outbound email** (optional): Select from **On** or **Off**.
- **Email addresses of recipients**: Enter the target email addresses (comma-separated). No more than 50 recipients are allowed per integration.

  Important: The notification emails can include confidential information, so be sure to carefully specify the email address of each recipient. To ensure privacy, one recipient cannot see the email addresses of the other recipients.
- **Deployment options**: Select one of the options, **Local** or **Remote**. **Local** deploys the integration in the same cluster and project (namespace) where IBM Cloud Pak for AIOps is installed. Alternatively, **Remote** deploys the integration in your chosen location, such as a different network region, on SaaS, or a remote on-premises VM, cluster, or container.

  Note: If you select **Remote** after adding the integration, you are provided with a bootstrap script to finish the deployment. Download and run the bootstrap script on the remote cluster to complete the deployment.

7. Click **Next**.
8. Customize the content for both the 'Incident created' and the 'Incident closed' emails. You can use the default email templates as-is, or customize them to include different content. A subject and a message must be included; otherwise, an email will not be sent.

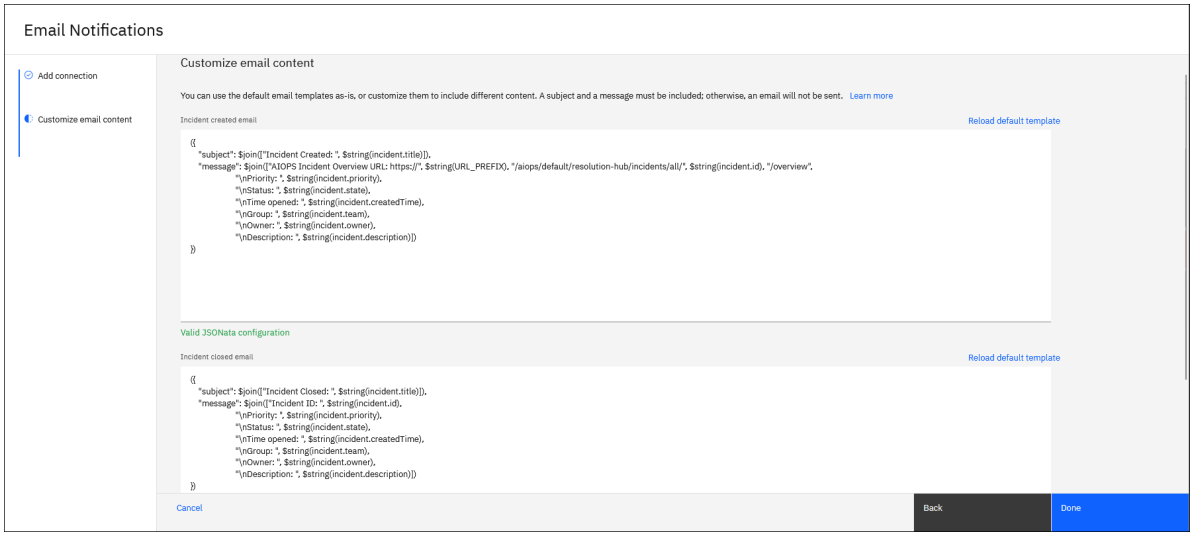

Figure. Customize Email Notifications content

9. Click **Done**. You are redirected to the *email notification* page for the integration.

Your new integration is listed in the table on the page. The integration has an initial status of *Initializing*. After a few minutes, the status changes to *Running* if your integration is successful.

Editing an email integration

After you create your integration, you can edit the integration. For example, if you want to add or change the listed recipient email addresses. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Email Notifications** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *Email Notifications* page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.

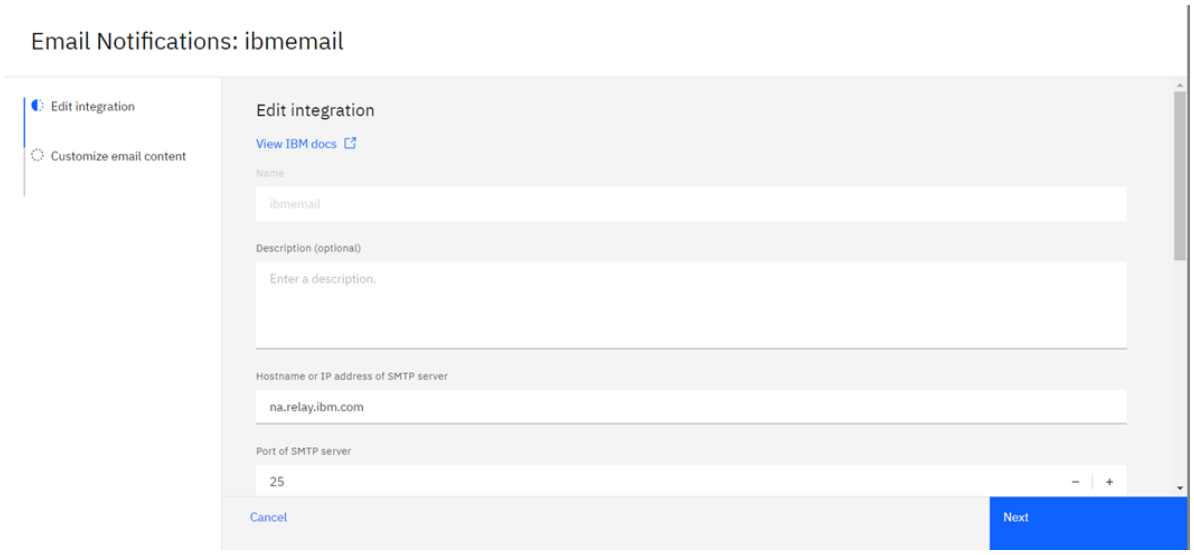

Figure. Edit Email Notifications integration

5. Edit your integration as required. Click **Save** when you are done editing.

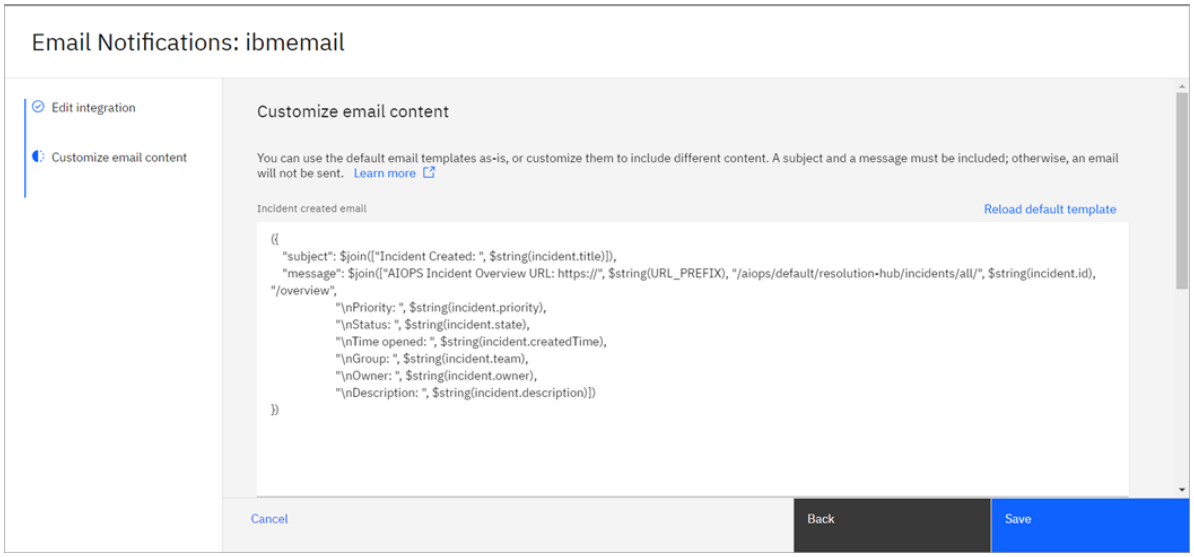

Figure. Edit Email Notifications integration - customize

Your integration is now edited.

Deleting an email integration

If you no longer need your integration and want to delete it entirely, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Email Notifications** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *Email Notifications* integrations page, click the *Delete* icon for the integration that you want to delete.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

   Your integration is deleted in IBM Cloud Pak for AIOps.

Creating GitHub integrations

Adding a GitHub integration enables your organization to create tickets when incidents are created in IBM Cloud Pak® for AIOps, discover details about similar tickets, and assess the risk of implementing proposed changes. Once a GitHub integration is set up and running, you can select it from the Notifications area of your Promote alerts to an incident policies.

- About this task
- Prerequisites
- Best practices
- Creating a GitHub integration
- Editing a GitHub integration
- Deleting a GitHub integration

About this task

Create one or more integrations by defining the integration details that are outlined here. Provide the URL and personal access token of your GitHub server, the GitHub repository, username, and the repository owner or organization. Optionally, specify field-mapping information for the incident details sent to GitHub when incidents are created. A default template is provided.

Prerequisites

You need the following information to create a GitHub integration:

- URL of your GitHub server
- Personal access token for your GitHub server
- GitHub username
- GitHub Owner or organization
- GitHub repository

Best practices

- When creating multiple GitHub connectors, use a different username and token to facilitate speedier data collection. There is a rate limit for GitHub API calls of about 5000/hr per individual and 15000/hr at enterprise level.
- Use a personal access token that does not expire.
- When Historical data collection is selected (see step 9), select a start date close to the date that will be used for AI training. Selecting a date further back might result in more API calls to GitHub, especially if there is a large volume of issues.

Creating a GitHub integration

To create a GitHub integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **GitHub** tile.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
    - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
    - **Description** (optional): Optionally, enter a description of the integration.
    - **URL of GitHub server**: Enter the URL of the GitHub server, for example `https://api.github.com/`. If you have any restrictive egress network policies in place, ensure that the policies are updated to allow for this outbound integration.
    - **Personal access token for GitHub server**: This token is used to authenticate your requests to access GitHub APIs. The owner of the token must have write access to the repository.

Figure. Add Github integration

Important: The selected scope of your GitHub repository must be "**repo**" with **Full control of private repositories**. To configure this in your GitHub repository, navigate to your profile > **Settings** > **Developer settings** > **Personal access tokens**.

- **Username**: Enter your GitHub username.
- **Owner or organization**: Enter the GitHub repository owner or organization.
- **Repository**: Enter the GitHub repository.

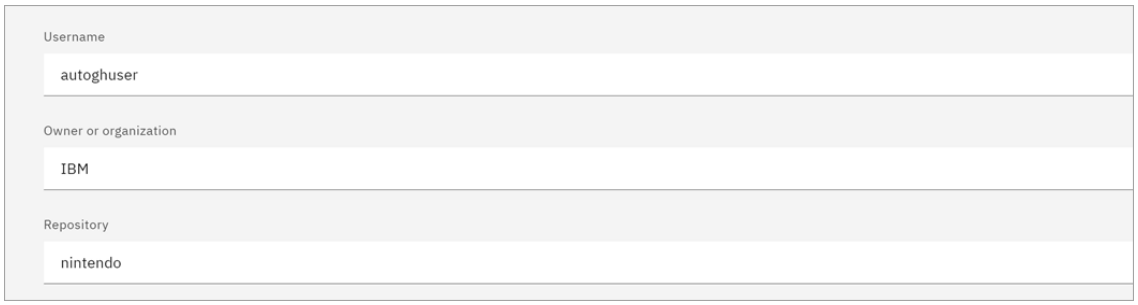

Figure. Add Github integration

7. Click **Next**.
8. You can use the default issue template as-is, or customize it to include different information. A title is required or the issue cannot be created. In addition to the fields included by default, you can also specify 'state' and 'assignees' for the incident. Incident 'priority' must be set in the label, otherwise the priority

will be appended and not replaced.

The owner of the token must have push access to the repository to set 'labels' and 'assignees' for new issues. Changes to 'labels' and 'assignees' are silently dropped if the user does not have push access to the repository.

Figure. Customize GitHub issue template

Note: **`$string(URL_PREFIX)`** reads from the **`URL_PREFIX`** environment variable to create the URL. The value for this variable is **`hostname`**.

9. Define how ticket data is collected:

   - **Data collection**: toggle to **Off** or **On**. The default is **On**. Note, if the rate limit for GitHub API calls is reached, an alert is sent to notify users that the connector is sleeping until the reset time from GitHub.
   - **Mode**: choose between **Live** or **Historical**. Live is the frequency at which data is sampled for GitHub issues in minutes (1-60 minutes). The default value is 1. For **Historical**, select a start date to retrieve closed GitHub issues since their last updated time.

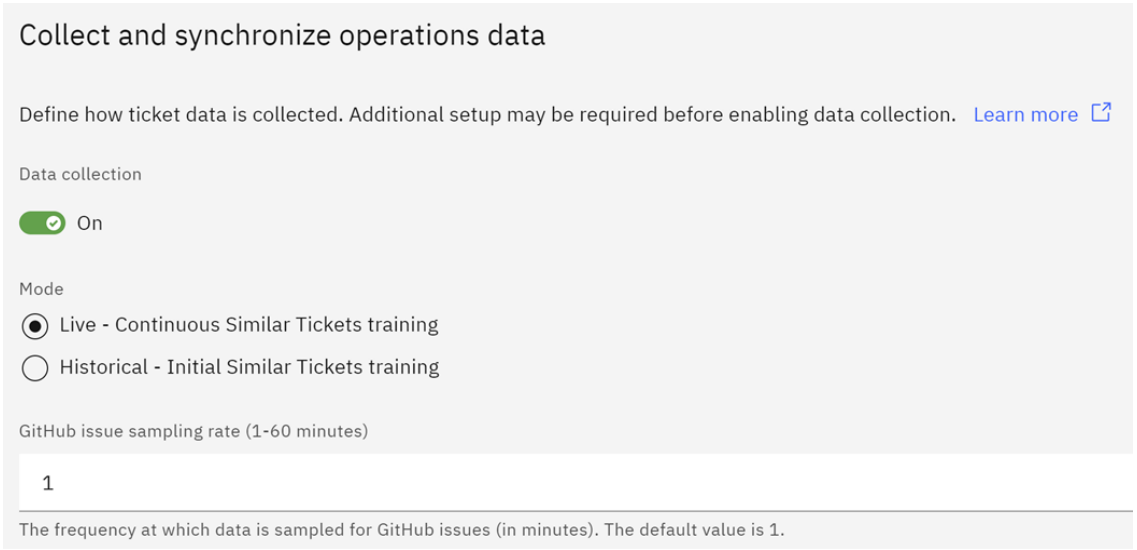

Figure. Collect and synchronize operations data

   Once the historical data is collected, you can train the data in **AI model management** using similar tickets training.

10. Click **Done**. You are redirected to the *GitHub integration* page.

Your new integration is listed in the table on the page. The integration has an initial status of *Initializing*. After a few minutes, the status changes to *Running* if your integration is successful. Once the integration is running, you can select GitHub as a ticketing option in your *Promote alerts to an incident* policies.

Editing a GitHub integration

After you create your integration, you can edit the integration. For example, if you want to customize the mappings in the issue template. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **GitHub** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *GitHub integration* page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited.

Deleting a GitHub integration

If you no longer need your integration and want to delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **GitHub** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *GitHub* integrations page, click the *Delete* icon for the integration that you want to delete.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

   Your integration is deleted in IBM Cloud Pak for AIOps.

Ansible Automation Platform integrations

You can create an integration to Ansbile Automation Platform. Red Hat Ansible Automation Platform provides tools for building and operating automation.

IBM supports Ansible as part of the Ansible Automation Platform. For more information about this platform, see Red Hat Ansible Automation Platform.

Note: You can create only one Ansible Automation Platform controller integration. Also, you must have an account with administrator role to create, edit, view, or delete an Ansible Automation Platform integration.

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating Ansible Automation Platform integrations

Complete the following steps to create an integration to an Ansible Automation Platform controller server.

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Ansible Automation Controller** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. Enter the base URL of your Ansible Automation Platform controller server. This URL must contain the protocol, for example: `https://ansible.mycompany.com:443`.
7. Choose an authentication type. You can select **User ID/Password** to connect with username and password, or **API Token** to use a bearer token, previously created with **Write Scope** in the Ansible.
8. Enter the chosen authentication information.
9. Optional: Enter the Ansible Automation Platform controller server root CA certificate, or the Ansible Automation Platform controller self-signed certificate.

   If the Ansible server certificate is based on a root CA certificate, then this root CA certificate must be entered (in PEM format). Some Ansible installations provide a self-generated root CA certificate (for example, at `<aap_install_dir>/tls/ca.cert`).

   If the Ansible server certificate is a self-signed certificate, then make sure the common name (CN) of the certificate matches the fully qualified domain name of the host system (a certificate with another CN like "localhost" will not be accepted). If needed, replace that certificate with a certificate that is issued for the actual domain name you are using.

   On Linux systems, enter the following command to receive the self-signed certificate:

   ```
   echo -n | openssl s_client -servername <ANSIBLE_TOWER_HOSTNAME> -connect <ANSIBLE_TOWER_HOSTNAME>:
   <ANSIBLE_TOWER_PORT> -showcerts | sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > file.cert
   ```

   If the command does not work in your environment, use the following variant of the command:

   ```
   ex +'g/BEGIN CERTIFICATE/,/END CERTIFICATE/p' <(echo | openssl s_client -showcerts -servername
   <ANSIBLE_TOWER_HOSTNAME> -connect <ANSIBLE_TOWER_HOSTNAME>:<ANSIBLE_TOWER_PORT>) -scq > file.cert
   ```

   If errors occur, make sure your exported certificate that is stored in `file.cert` contains a full and valid certificate. Errors like `verify error:num=20:unable to get local issuer certificate` occur due to a missing CA root certificate for the DigiCert CA.

   The resulting file.cert might contain one or more certificates and each certificate begins and ends as follows:

   ```
   -----BEGIN CERTIFICATE-----
   ...
   -----END CERTIFICATE-----
   ```

   On Windows systems, use your preferred browser to export the certificate or certificate chain.

10. Click **Done** to complete the Ansible Automation Platform integration.

Note: See Ansible actions for additional information on the supported Ansible versions and some other restrictions.

Creating an IBM Db2 integration

BETA The IBM Db2 integration is available only for technology preview, and is not for production usage.

Adding an IBM® Db2® integration enables your organization to store incident data in a Db2 database. The incident data can then be included in custom dashboards and reports that are created in IBM Cognos® Analytics.

- Prerequisites
- Creating an IBM Db2 integration
- Editing an IBM Db2 integration
- Deleting an IBM Db2 integration

Prerequisites

You need the following information to create an IBM Db2 integration:

- Data source type
- Name of the IBM Db2 database
- Hostname or IP address at the database
- Port number for incoming client connections
- Username and password to access the database

Note: The IBM Db2 integration is only supported on Red Hat® OpenShift® Container Platform clusters. IBM Db2 integration is not supported on IBM Cloud Pak for AIOps on Linux.

Creating an IBM Db2 integration

To create an IBM Db2 integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **IBM Db2** tile.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
    - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
    - **Description** (optional): Optionally, enter a description of the integration.
    - **Data source type**: From the drop-down menu, select the type of IBM Db2 database.
    - **Database hostname or IP address**: Enter the fully qualified hostname or IP address of the IBM Db2 database, for example, `myserver.abc.com` or `192.0.2.24`.
    - **Database port (1024 - 65535)**: Enter the database port number.
    - **Database name**: Enter the name of the IBM Db2 database.

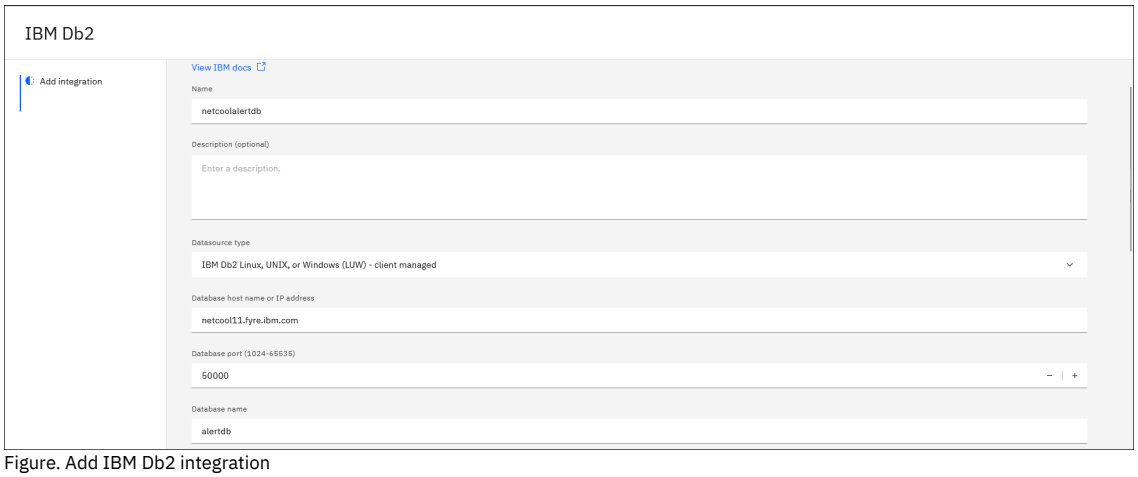

Figure. Add IBM Db2 integration

- **Username**: Enter the username to access the IBM Db2 database.
- **Password**: Enter the password for the IBM Db2 database username.
- **Schema qualifier (optional)**: Enter the schema qualifier for the database objects to be accessed. If blank, the username is used.
- **Maximum pool size (0 - 100000)**: Enter the maximum number of connections allowed within a single connection pool. The default value is 0, which indicates that connection pooling is switched off for the integration server.
- **Additional database parameters (optional)**: Enter additional database parameters in the format `name1=value1;name2=value2`.

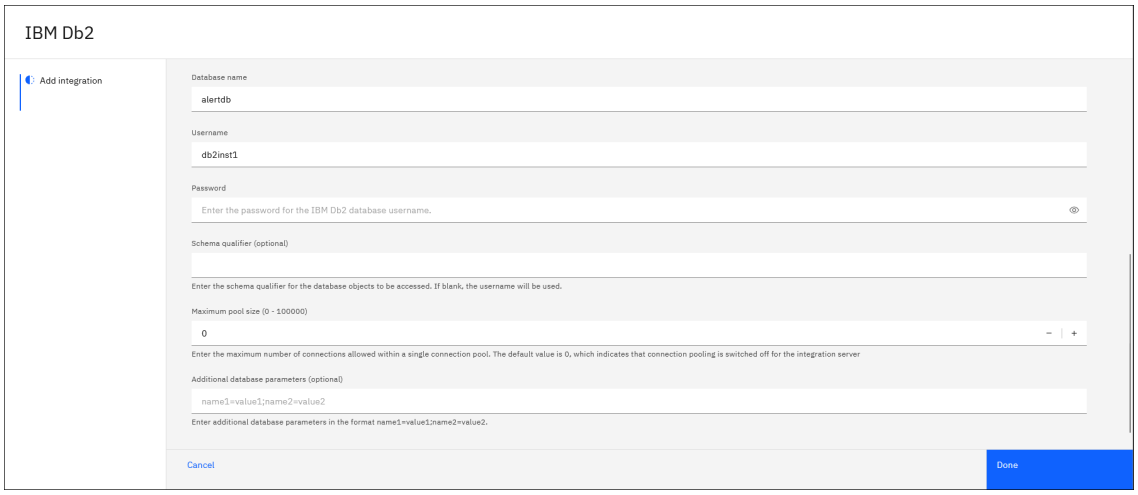

Figure. Add IBM Db2 integration

7. Click **Done**. You are redirected to the *IBM Db2 integration* page.

   Your new integration is listed in the table on the page. The integration has an initial status of *Initializing*. After a few minutes, the status changes to *Running* if your integration is successful.

Create a policy to populate a dashboard or report

Once an IBM Db2 integration is set up and running, you can create a policy to send alerts or incidents from Cloud Pak for AIOps to populate a dashboard or report in IBM Cognos® Analytics. For more information, see Populate a dashboard or report.

Editing an IBM Db2 integration

After you create your integration, you can edit the integration. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Db2** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *IBM Db2 integration* page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited.

Deleting an IBM Db2 integration

If you no longer need your integration and want to delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Db2** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *IBM Db2* integrations page, click the *Delete* icon for the integration that you want to delete.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

   Your integration is deleted in IBM Cloud Pak for AIOps.

Incoming integrations

Incoming integrations enable IBM Cloud Pak for AIOps to collect log, metric, and event data from various sources.

IBM Cloud Pak for AIOps uses this collected data to establish baseline models during AI model training. These models are then used to compare against live incoming data from these integrations to report anomalous activity to you in near real time by way of your outgoing integrations. In live data mode, the integration might need a delay to offset the query time windows to provide time buffer to prevent retrieving partial real-time data. For more information, see Delay configuration in data integrations.

The recommended value for source parallelism should be equal to the number of days. For example, if you are pulling historical data for training for 7 days, the source parallelism should be around 7 or higher, so that you can pull data for multiple days simultaneously.

Unlike outgoing integrations, you can set up multiple sources of incoming integrations. For example, if you have a single source of Falcon LogScale data for logs, and PagerDuty configured for events, you can create integrations for both of those. You can also use the custom and Kafka integrator for greater flexibility. The custom integration type collects data from a single specific data source (like any other integration type). If you want to collect log data from different systems, and then route that information through a forwarding agent, such as an Apache Kafka topic (like Sysdig or FluentBit), you can use the Kafka integration type.

Note: The ServiceNow integration type has optional incoming and outgoing facets.

For more information about incoming integrations, see the following topics:

- Administrator process integrations
- Appdynamics integrations
- AWS CloudWatch integrations
- Custom integrations
- Dynatrace integrations
- ELK integrations
- Falcon LogScale integrations
- Generic webhook integrations
- IBM Netcool Operations Insight ObjectServer integrations
- IBM Tivoli Netcool/Impact integrations
- Instana integrations
- Kafka integrations
- Mezmo integrations
- New Relic integrations
- Observer integrations
- PagerDuty integrations
- Splunk integrations
- Zabbix integrations

Creating AppDynamics integrations

An AppDynamics integration can provide Cloud Pak for AIOps metric and topology data for the applications or infrastructure that you monitor.

You need to have both an endpoint and basic authentication ready. The AI Algorithm that analyzes AppDynamics data is Metric anomaly detection. AppDynamics SaaS controller 22.5 is the version that is supported for the AppDynamics integration.

For more information about working with AppDynamics integrations, see the following sections:

- Creating AppDynamics integrations
- Enabling AppDynamics integrations
- Editing AppDynamics integrations
- Deleting AppDynamics integrations
- Adding an AppDynamics data retention period

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating AppDynamics integrations

To create an AppDynamics integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **AppDynamics** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and select from the following options:

   - **Select the data types that you need to collect**: Select the relevant checkbox for *Metrics* or *Topology*.
   - **Specify whether you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visability to AppDynamics* radio buttons.

- **Select Cloud Pak for AIOps integration**: You can leave this at the default *Use the integration that is recommended by Cloud Pak for AIOps*, which will be whichever you selected out of *Metrics* or *Topology* in the *Select the data types that you need to collect* field, or you can deselect this and then select between just *Metrics* or *Topology*.

  The below steps are for selecting *Metrics* but if you do select *Topology* then you will be brought to a *New observer job* page. An AppDynamics integration provides topology data through an observer that supports the discovery of business applications, nodes and tiers. When an AppDynamics observer job is run, it will gather and read data from the AppDynamics Controller via REST API. For more information, see Configuring an AppDynamics observer job.

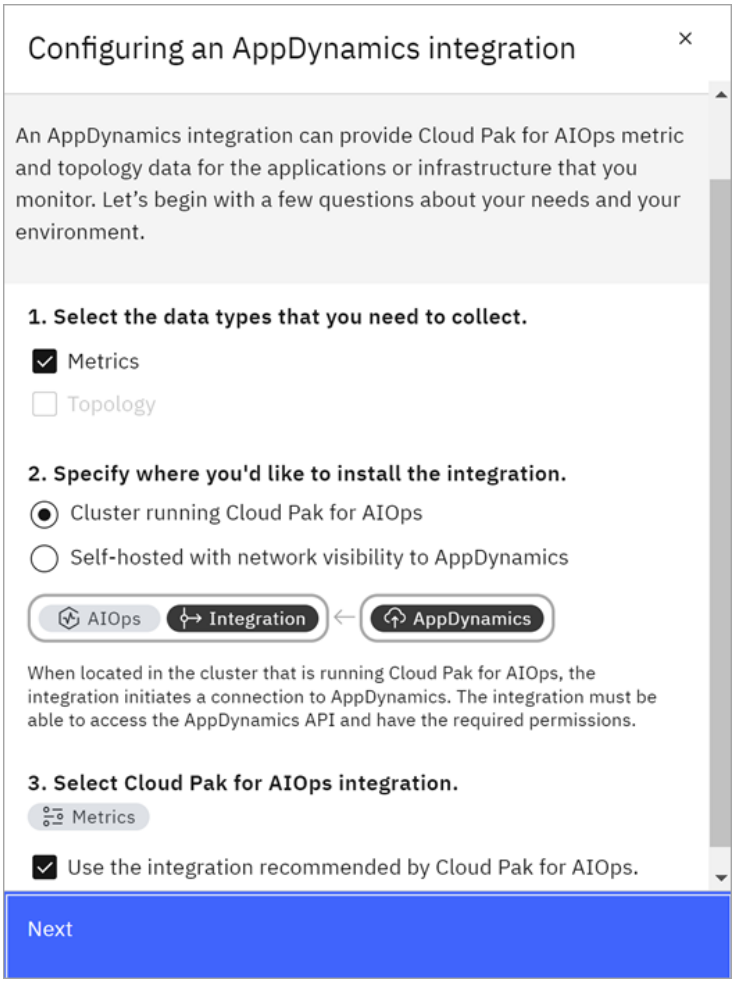

Figure. Configuring an AppDynamics integration

6. Then click **Next**.

   You see an overview, further direction such as *what you need to have ready* and also *what algorithms analyze AppDynamics data*.

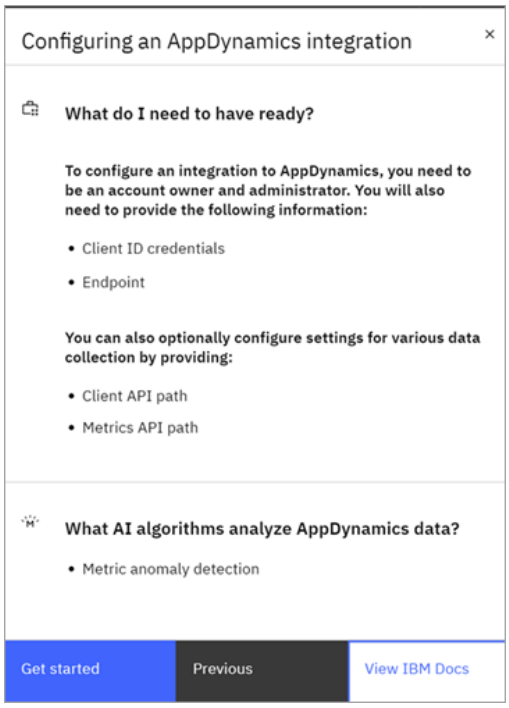

Figure. Get started

7. Click **Get Started**.
8. On the *Add integration* page, define the general integration details:
    - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
    - **Description**: An optional description for the integration.
    - **Endpoint**: Enter an endpoint for the integration, which in this case is the AppDynamics data source base URL of your account. For example `https://myinstance.saas.appdynamics.com`.
    - **Client ID**: Client ID is generated from the AppDynamics controller, in the format 'ApiClientName@AccountName', for example 'aiops@ibm', where 'aiops' is the API Client name, and 'ibm' is the AppDynamics account name.

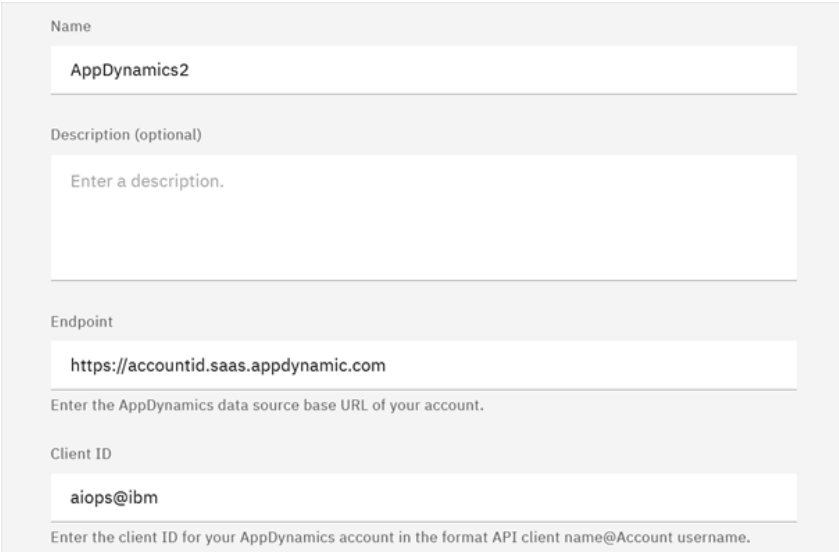

Figure. Add AppDynamics integration

- **Client Secret**: Generated from **AppDynamics UI -> Settings -> Administration -> API Clients**. Enter the Client secret for the application. Also, ensure that the Client Secret created has the following roles: Account Owner, Administrator, or Applications and Dashboards Viewer, which is the minimum role. If not, the API calls might not return valid application IDs.
- **Deployment options**: Select between 'Local' and 'Remote' radio buttons. If you pick 'Remote', then after you add the integration, you are provided with a bootstrap command to finish the orchestration. Run the bootstrap script on the remote server where you want to deploy the integration remotely.

  Important: Podman must be installed to execute the remote deployment script with a recommended minimum version of 4.4.1. Read and write access are required for the folder where the remote deployment script will be executed and the script also must have execution permissions in order to be run. No more than one remote deployment script should be executed per host.

9. To verify the SSL/TLS configuration:
    1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
    2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.
10. Click **Test Connection**. If successful, a Test succeeded message is displayed.

Figure. Test connection

11. Click **Next**.
12. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to AppDynamics via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server. **Note:** The URL for the metrics-only integration should have the protocol in the URL.
    - **Port number of proxy server**: Enter a port. The default is 8080.

    Note: Only unauthenticated HTTP proxy is supported.
13. Click **Next**.
14. Enter the following *Collect metric data**: Define how you want to collect metric data.

- **Enable data collection**: Set the toggle button to on.
- **Fill out Code field**: Enter Application name and corresponding Metric paths as JSON, using the following format:

```
{"Application Name":"[metric path1, metric path2, metric path3]"
}
```

Example

```
{
"helloworld":"[Overall Application Performance|Calls per Minute,Overall Application Performance|Average Response Time (ms),Overall Application Performance|mytier|Average Response Time (ms)]",
"products-ecommerce":"[Overall Application Performance|*,Business Transaction Performance|Business Transactions|DwightVM|*|*]",
"Database Monitoring":"[Databases|admin2|KPI|*,Databases|mysql-admin| Server Statistic|*]"
}
```

To get the metric path, go to the AppDynamics Console, select the application > Metrics Browsers > choose the metrics that you want to monitor > right-click and select 'Copy Full Path'.

15. You can chose between collecting historical or live data. If you want to collect live data you need to click the **Only click Live data once the integration is established** checkbox. If you do not you need to fill out the following fields for historical data collection:
    - **Enter Start date**: Enter the start date *mm:dd:yyyy*.
    - **Enter Start time**: Enter the start date and time in the format *hh:mm* (hours and minutes).
    - **Set LocalTime**: Pick the time zone required from the dropdown list.

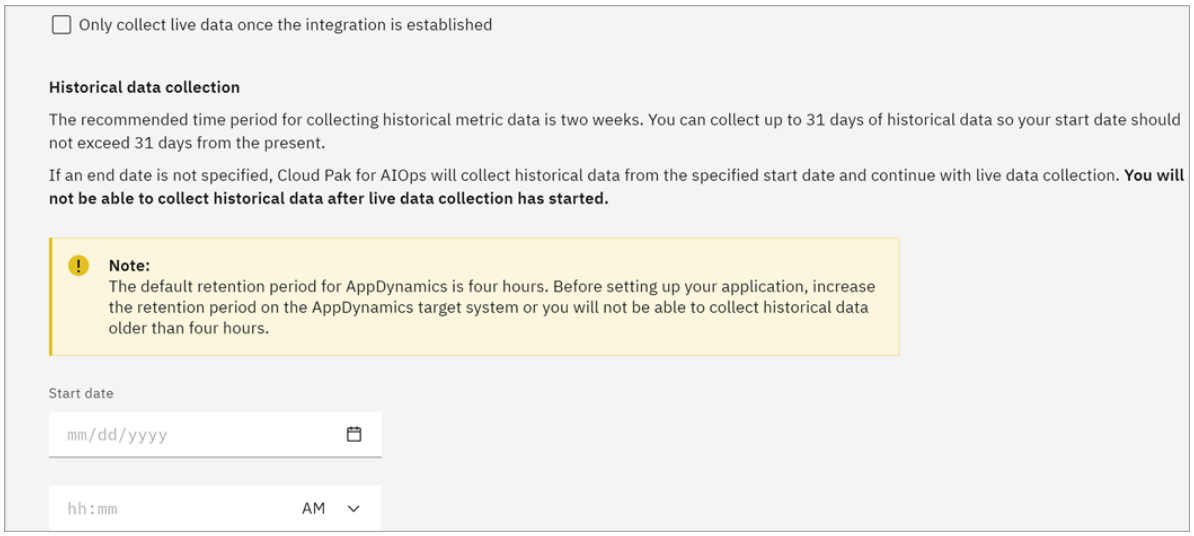

Figure. Collect metric data

Click the **Add end date** button if you want to add an end date. There is also a *Remove End date* button.The following fields appear:

- **End date**: Enter the end date *mm:dd:yyyy*.
- **End time**: Enter the end date and time in the format *hh:mm* (hours and minutes).
- **Scheduler run time (minutes)**: The frequency at which the live scheduler should run. The default is 5 mins.

Note: For historical metric data collection, the recommended time period is two weeks. You can collect up to 31 days of historical data so your start date should not exceed 31 days from the present. If an end date is not specified, Cloud Pak for AIOps will collect historical data from the specified start date and continue with live data collection. You will not be able to collect historical data after live data collection has started. The default retention period for AppDynamics is four hours. Before setting up your application, increase the retention period on the AppDynamics target system or you will not be able to collect historical data older than four hours.

If you click the *Live* data radio button the field to complete is:

- **Scheduler run time (minutes)**: The frequency at which the live scheduler should run. The default is 5 mins.

16. Click **Done**.

For more information about adding an AppDynamics data retention period, see Adding an AppDynamics data retention period.

For more information about performance considerations for metric data collection, see Performance considerations for metric data collection.

You created an AppDynamics integration in your instance. After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling AppDynamics integrations.

Note: An error that might show if no data is set for particular metrics or applications can resemble the following message.

```
2022-06-22 04:59:07,578 INFO [Default Executor-thread-3]
com.ibm.watson.aiops.connectors.service.AppdynamicsWebClientService : Bad Request
[err] javax.ws.rs.BadRequestException: BadRequest
[err] java.lang.NullPointerException
```

In order to avoid this error, ensure the application name and metrics path configured are valid. Also, ensure that the Client Secret created previously has the following roles: Account Owner and Administrator. If not, the API calls might not return valid application IDs.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Enabling and disabling AppDynamics integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **AppDynamics** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect metric data* section. Set **Enable data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting an integration, see Deleting AppDynamics integrations.

Editing AppDynamics integrations

After you create your integration, your can edit the integration. For example, if you specified *Historical mode* but now want your integration to pull in live data for continuous monitoring, you can edit it. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **AppDynamics** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the AppDynamics integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

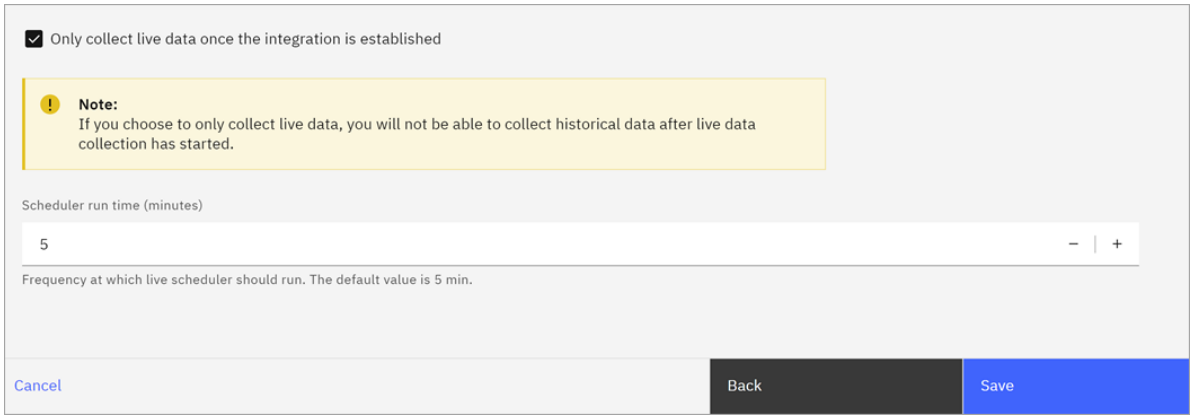

Figure. Edit AppDynamics integration

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling AppDynamics integrations. For more information about deleting an integration, see Deleting AppDynamics integrations.

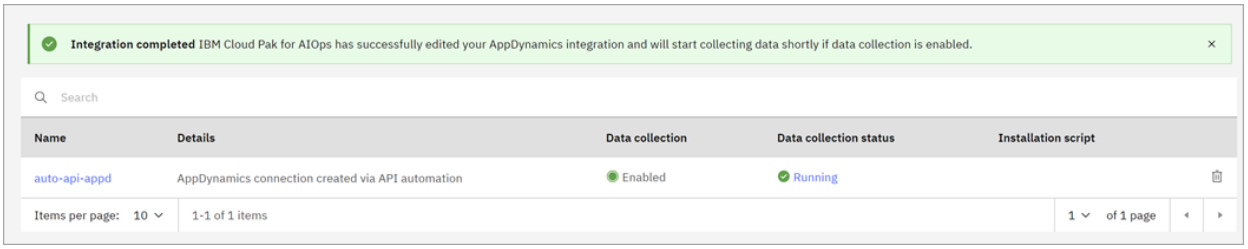

Figure. AppDynamics integration created

Deleting AppDynamics integrations

If you no longer need your AppDynamics integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **AppDynamics** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the AppDynamics integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Adding an AppDynamics data retention period

The default data retention period for AppDynamics is 4 hours. Metric anomaly detection uses up to two weeks of data to build models and without historical data to collect, it is several days to a week before anomalies start to be detected and raised without having historical data to quickly train up the algorithms.

Consider whether it is possible to increase the AppDynamics data retention period in advance so that the analytics can train up more quickly. To increase the data retention period in AppDynamics, consult the relevant AppDynamics retention documentation.

Creating AWS CloudWatch integrations

An AWS integration can provide CloudPak for AIOps metric, event, and topology data for the applications or infrastructure that you monitor.

To activate the integration, you must have an endpoint, an access key, and a secret key ready. You can select the metrics that you want to monitor by choosing the associated namespaces in the IBM Cloud Pak for AIOps console. The Metric anomaly detection AI algorithm analyzes the AWS CloudWatch data.

For more information about working with AWS CloudWatch integrations, see the following sections:

- Creating AWS CloudWatch integrations
- Enabling and disabling AWS CloudWatch integrations
- Editing AWS CloudWatch integrations
- Deleting AWS CloudWatch integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating AWS CloudWatch integrations

To create an AWS CloudWatch integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **AWS CloudWatch** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and select your required options from the following sections:
   - **Select the data types that you need**: Select the relevant checkbox for *Metrics*, *Events*, or *Topology*.
   - **Specify whether you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visability to Dynatrace* radio buttons.
   - **Select Cloud Pak for AIOps integration**: You can leave this at the default *Use the integration recommended by Cloud Pak for AIOps*, or deselect it, and change to just *Metrics*, *Events*, or *Topology*.

     The below steps presuppose you select *Metrics* but if you do select *Events* then there will be a *Collect event data* page to complete, and if you select *Topology* then you will be brought to a *New observer job* page. The AWS observer reads services data from AWS through the AWS SDK and generates a topology. The AWS Observer supports multiple Amazon Web Services (AWS) services such as EC2 for its compute services. For more information, see Configuring an AWS observer job.
6. Then click **Next**.

   You see an overview, further direction such as *what you need to have ready* and also *what algorithms analyze Dynatrace data*.

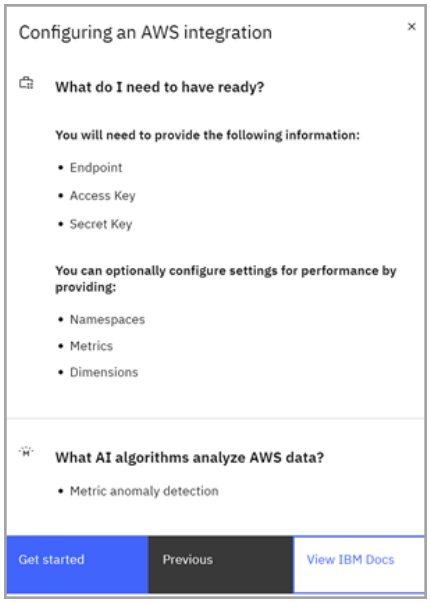

Figure. Configure AWS integration - get started

7. Click **Get Started**.
8. On the *Add integration* page, define the general integration details:
   - **Name**: Type in the display name of your integration.
   - **Description**: Provide an optional description for the integration.
   - **Endpoint**: Enter an endpoint for the integration. For example `https://monitoring.us-east-1.amazonaws.com`.

Figure. Add AWS integration

- **Access Key**: Enter an Access Key for the integration.
- **Secret Key**: Enter a Secret Key for the integration. For getting access and secret keys, contact admin.
- **AWS CloudWatch region**: Select a region from the available regions in AWS, for example, us-east-1.
- **Deployment options**: Select one of the following options: **Local** or **Remote**.

  The **Local** option deploys the integration in the same cluster where IBM Cloud Pak for AIOps is installed. Alternatively, the **Remote** option deploys it in your chosen location. If you select the **remote** option, you are provided with a bootstrap command after adding the integration to finish the deployment.

9. To verify the SSL/TLS configuration:
   1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
   2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.
10. Click **Test connection**. A message stating whether the test succeeded or failed is displayed.

Figure. Test connection

11. Click **Next**.
12. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to AWS CloudWatch via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server.
    - **Port number of proxy server**: Enter a port. The default is 8080.

    Note: Only unauthenticated HTTP proxy is supported.

13. Click **Next**.
14. Enter the following *Collect metric data* information. It defines how you want to collect metric data.
    - **Enable data collection**: Set the toggle button to on.

Note: If you disable data flow, a new integration is created, but metrics are not collected.

- **Namespace**: Select one or more namespaces from the list to see its associated metrics in the filter table. By default, all metrics are selected in the table. You can search and select or remove metrics from it.
- **Aggregation interval (minutes)**: Enter a value in minutes. This value is the frequency at which data is collected. The default value is 5 minutes.
- Select live or historical data collection

  Note: If you choose to collect only live data, you cannot collect historical data after the live data collection starts. However, if you collect historical data, you can continue live data collection afterwards.

  - Live data collection: To collect live data, complete the following steps:
    - **Only collect live data once the integration is established**: Select the checkbox.
    - **Scheduler run time (minutes)**: Enter a value in minutes. The value represents the frequency at which live scheduler runs. For example, if you set the value to 10 minutes, the live scheduler runs every 10 minutes. The default value is 5 minutes.
  - Historical data collection: To collect historical data, complete the following steps:
    - **Start date and time**: Select the start date from the calendar and enter the time in the 'hh:mm' format (hours and minutes).

      Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.
    - **Time zone**: Select your time zone from the dropdown list.
    - **End date and time**: Select a date from the calendar. Also, enter the time in the hh:mm format (hours and minutes). If you want to the end date, click **Remove end date**.

      Note: If you do not set an end date, IBM Cloud Pak for AIOps collects historical data from the specified start date and continues with live data collection. You cannot collect historical data after the live data collection starts.
    - **Scheduler run time (minutes)**: Enter a value in minutes. The value represents the frequency at which live scheduler runs. The default value is 5 minutes.

      Note: Scheduler run time is only applicable to live mode. You must configure the scheduler run time only if you do not add an end date as the integration will continue to run in live mode after historical mode.

15. Click **Done**.

For more information about performance considerations for metric data collection, see Performance considerations for metric data collection.

Enabling and disabling AWS CloudWatch integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **AWS CloudWatch** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect metric data* section. Set **Enable data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting AWS CloudWatch integrations.

Editing AWS CloudWatch integrations

After you create your integration, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **AWS CloudWatch** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the AWS CloudWatch integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Deleting AWS CloudWatch integrations

If you no longer need your AWS CloudWatch integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.

2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **AWS CloudWatch** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the AWS CloudWatch integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating custom integrations

IBM Cloud Pak for AIOps provides many connectors, probes, and observers by default for setting up integrations with common IBM and third-party systems and services. If a default integration is not available for connecting to a system or service that you want to use with IBM Cloud Pak for AIOps, you can set up a custom integration to connect to that system or service.

You can use a custom integration to ingest user-defined log data, which is used to establish a baseline of normal behavior and then identify anomalies. These anomalies can be correlated with other alerts and events and published to your ChatOps interface, which help you determine the cause and resolution of a problem.

Due to each user-defined data source having different formats and sizes, not all log sources can be ingested directly with this custom integration. For more information, see Data source requirements.

Important: Custom integrations cannot use historical data for initial AI training.

Note: As an alternative to using the **Custom** integration that is provided by default, you can create your own integration connector to interact with IBM Cloud Pak for AIOps. For instance you can create a custom connector for sending events, metrics, and topology data to IBM Cloud Pak for AIOps from an external source when a default integration is not available. For more information see Creating custom integrations using the integration SDK

For more information about working with custom integrations, see the following sections:

- Data source requirements
- Creating custom integrations
  - Customizing `GET` and `POST` integrations
  - Custom mappings
- Enabling custom integrations
- Editing custom integrations
- Deleting custom integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Data source requirements

Before creating the integration, you should be aware of the following information.

- **Format of source data**: The data that is ingested with the log integration must be in newline-delimited JSON format. Each individual log entry must be on a separate line and each log entry must be less than 1 MB, otherwise the custom integration is not able to ingest the data. The following code snippet shows an example of the newline-delimited JSON format:

  ```
  {"message": "exampleMessage", "time": 500}

  {"message": "exampleMessage", "time": 500}
  ```

  Custom integrations support the ingestion of flat JSON source data but do not support nested key-value pairs. The following examples illustrate what is supported and what is not.

  Supported JSON source data: the following code snippet shows an example of flat JSON source data.

  ```
  {
     "message": "exampleMessage",
     "time": "..."
  }
  ```

  Unsupported JSON source data: the following code snippet shows an example of nested key-value pairs.

  ```
  {
     "log":["message": "exampleMessage","timezone": "exampleTimezone"],
     "time": "..."
  }
  ```

  Important: If your data does not conform with the preceding format, the custom integration is not be able to ingest the data. Review the requirements before creating your custom integration.

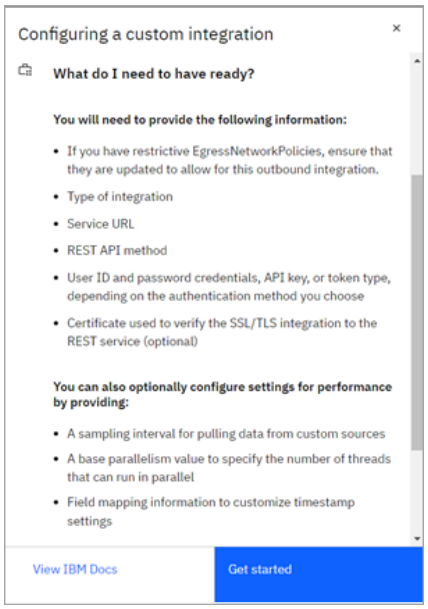
- **Load**: To prevent this integration placing an inordinate load on your data source and potentially impacting your logging operations, this integration only connects to one API with a default data frequency of 60 seconds. This is controlled by using the **Sampling rate** setting in the Procedure section.
- **Access**: Custom data sources are cloud-based REST APIs. Access is configured by using the authentication methods that are specified in the **Authentication type** setting in the Procedure section.
- **Data volume**: Data volume depends on the application, and is not a set value. Therefore, it does not appear in the settings.

Note: If you want to collect log data from multiple systems and then route that information through a forwarding agent, such as an Apache Kafka topic (for example, Sysdig or FluentBit), you must use the Kafka integration type. For more information about Kafka integrations, see Creating Kafka integrations.

Creating custom integrations

The custom integration type collects newline-delimited JSON from a single specific data source.

Procedure



To create a custom integration from a specific source, step through the following sections:

- Adding a Custom integration
- Specifying integration parameters
- Specifying field mapping
- Specifying how log data is collected for AI training

Adding a Custom integration

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Custom** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.

Specifying integration parameters

1. On the *Add integration* page enter the following integration information:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **Extract data from an array of log lines embedded in JSON**: When enabled, logs are extracted from an array that is embedded within a JSON object that is returned by the REST service. This option works only for an array of flat JSON objects that is embedded within a JSON object.

     
     Custom integration
   - **Embedded array path**: Type the path to the array from which you want to extract log data. The following examples, show how to configure the array path:

     ```
     {"results": [{"message": "myMessage"}]} would be results[*]
     {"results": {"events": [{"message": "myMessage"}]}} would be results.events[*]
     {"results": [{"events": [{"message": "myMessage"}]}]} would be results[0].events[*]
     ```
   - **REST method**: The method by which your data gets transferred, either `GET` or `POST`. If you select *POST* a *POST JSON (Optional)* field appears also.

- **Authentication type**: Select one of the following values:
  - **User ID/password**: The user ID and password that is required for accessing the REST service. You must enter both in the integration configuration. The HTTPS authentication header is sent to the Service URL in the format 'Authorization: Basic MyCredential'. 'MyCredential' is base64 encoded and in the format 'username:password'.
  - **API key**: The REST service is authenticated with an API key. The HTTPS authentication header is sent to the Service URL in the format 'Authorization: MyAPIKey'.
  - **Token**: The REST service is authenticated with a temporary token. The HTTPS authentication header is sent to the Service URL in the format 'Authorization: Bearer MyToken'.
  - **Query Key**: The REST service is authenticated with a query key. The HTTPS authentication header is sent to the Service URL in the format **`x-Query-Key: MyQueryKey`**.
  - **Custom**: Your custom REST service has specific authentication requirements that are not covered by the other authentication methods. You must enter both a Header and Value to configure your authentication. Note, both the Header and Value are plain text properties that are case-sensitive and does not remove spaces. The HTTPS authentication header is sent to the Service URL in the format 'Authorization: MyHeader MyValue'.
  - **None**: Your custom REST service requires no authentication. No Authorization header is sent to the target system.
- **Certificate (optional)**: Certificate used to verify the SSL/TLS connection to the REST service.
- **UI URL**: The hostname or IP address of the UI of your custom source.
- **Service URL**: The URL for the service that you want to integrate. For more information about customizing your *Service URL*, see Customizing GET and POST integrations

  Custom integration
- **Base parallelism**:It is recommended to use a higher value than 1 so that you can process data in parallel. In a small environment the available flinks slots is 16 and for a large environment, the maximum available slots is 32.
- **Sampling rate**: The rate at which data is pulled from live source (in seconds). The default value is **`60`**.
- **JSON processing option**: Select a JSON processing option.
  - **None**: The default option. The JSON is not processed or modified.
  - **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
  - **Filter**: This option extracts the JSON object and replaces it with an empty string.

- For more information about the options, see Managing embedded JSON.

Note: To improve data throughput, you can increase the base parallelism value incrementally. For more information about maximum base parallelism for starter and production deployments, see Improving data streaming performance for log anomaly detection.

2. Click **Test connection**.
3. Click **Next** to move to the next page.

Specifying field mapping

1. On the *Field mapping* page you can improve search performance by mapping the fields from your implementation fields to standard fields within IBM Cloud Pak for AIOps.

   - For more information about how field mappings are defined, see Mapping data from incoming sources.
   - For more information about using mappings to clean your data for use in IBM Cloud Pak for AIOps, see Cleaning mapped data using regular expressions.

   The following code snippet displays an example of field mapping that uses the supported format. When you are coding your mapping, use this example to help you.

```
{
  "codec": "custom",
  "message_field": "message",
  "log_entity_types": "kubernetes.container_name",
  "instance_id_field": "_app",
  "timestamp_settings":{
     "timestamp_field":"_ts", <MANDATORY>
     "multiplier": 1000, <OPTIONAL>
     "pattern": "yyyy-MM-dd hh:mm:ss z" <OPTIONAL, SPECIFIC TO RAW DATA OUTPUT>
  }
}
```

   If you are configuring an integration to WebSphere, then you must use the following mapping. In this mapping, all fields must be specified exactly as shown, except for the **log_entity_types** parameter. This can be empty, as shown in the following example.

```
{
"codec": "custom",
"rolling_time": 10,
"instance_id_field": "ibm_serverName",
"log_entity_types": "",
"message_field": "message",
"timestamp_settings": {
   "timestamp_field": "ibm_datetime",
   "pattern": "yyyy-MM-dd'T'HH:mm:ss.SSSZZZZZ"
                      }
}
```

   For more information about specific custom mappings, see Custom mappings.

   Alternatively, if you want to include specific fields from your WebSphere record within the log alert **resource** field to be generated by the log anomaly detection algorithms, then specify those WebSphere fields in the **log_entity_types** parameter, as shown in the example below.

```
{
"codec": "custom",
"rolling_time": 10,
"instance_id_field": "ibm_serverName",
"log_entity_types": "host,ibm_userDir,ibm_serverName,module",
"message_field": "message",
"timestamp_settings": {
   "timestamp_field": "ibm_datetime",
   "pattern": "yyyy-MM-dd'T'HH:mm:ss.SSSZZZZZ"
                      }
}
```

   For more information about the log alerts generated by the log anomaly detection algorithms, see the following topics:

   - Natural language examples
   - Statistical baseline examples

2. Click **Next** to move to the next page.

Specifying how log data is collected for AI training

1. On the *AI training and log data* page, select how you want to manage collecting data for use in AI training and anomaly detection. Click the *Data collection* toggle to turn on data collection then select how you want to collect data:

   - **Live data for continuous AI training and anomaly detection**: A continuous collection of data from your integration is used to both train AI models and analyze your data for anomalous behavior.

     Note: After an initial installation, there is no data at all in the system. If you select this option, then the two different log anomaly detection algorithms behave in the following ways:

     - Natural language log anomaly detection does not initially detect anomalies as no model has been trained. If **Live data for continuous AI training and anomaly detection** is set to on, the system gathers training data live and after a few days there is enough data to train a model. When this model is deployed, then it detects anomalies as normal.

- Statistical baseline log anomaly detection does not detect anomalies for the first 30 minutes of data collection. This is because it does not have a baseline yet. After 30 minutes of live data collection the baseline is automatically created. After that it detects anomalies on an ongoing basis, while continuing to gather data and improve its model every 30 minutes.

- **Live data for initial AI training**: A single set of training data used to define your AI model. Data collection takes place over a specified time period that starts when you create your integration.

  Note: Selecting this option causes the system to continue to collect data while the option is enabled; however, the data is collected for training only, and not for log anomaly detection. For more information about AI model training, including minimum and ideal data quantities, see Configuring AI training.

2. **Important**: Keep in mind the following considerations when you select your data collection type:

   - Anomaly detection for your integration occurs if you select *Live data for continuous AI training and anomaly detection*.
   - Custom integrations cannot use historical data for AI training.
   - Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.
3. Click **Next**.
4. On the *Resource requirements* page, you can review the slot usage for your log integrations to see if there are enough slots to fully support the integration for multizone high availability.

   If you set the **Data collection** toggle to **On**, you will see the resource management overview.

   - If your current usage and other usage are less than the provisioned slots, but the HA slots exceed the provisioned slots, you will be able to create the integration, but will see a warning that you do not have enough slots. The integration will not have multizone high availability.
   - If your projected usage exceeds the provisioned slots, you will not be able to create the integration because you do not have enough slots on your system for log data integrations.
   - If your total slots, including HA slots, are within the provisioned slots, the integration will have multizone high availability.

     Note: HA operation assumes high availability for three zones.

   If you set the **Data collection** toggle to **Off**, you will see a message stating that you need to enable logs data collection to see the resource management overview. When data collection is off, no slots are used by that integration.
5. Click **Done**.

You have created a custom integration in your instance. After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling custom integrations.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Customizing `GET` and `POST` integrations

`GET` integrations

If you customize the *Service URL* of your integration, you must include the start and end time in the URL with properly formatted timestamps (`SimpleDateFormat`). For epoch timestamps, milliseconds and seconds are supported. The following timestamp identifiers are supported in the **Service URL** field:

- <start-epoch-ms>, <end-epoch-ms>. For example, `http://exampleurl.com/v1/export?to=<end-epoch-ms>&from=<start-epoch-ms>`.
- <start-epoch-s>, <end-epoch-s>. For example, `http://exampleurl.com/v1/export?to=<end-epoch-s>&from=<start-epoch-s>`.
- <start-`SimpleDateFormat`>, <end-`SimpleDateFormat`>. For example, `http://exampleurl.com/v1/export?to=<end-yyyy-MM-dd'T'HH:mm:ss.SSSXXX>&from=<start-yyyy-MM-dd'T'HH:mm:ss.SSSXXX>`.

`POST` integrations

For `POST` integrations, you do not need to customize the *Service URL* value. For these integrations, the payload is in the body of the JSON and you can customize the format, but must include the start and end times with properly formatted timestamps (`SimpleDateFormat`). For epoch timestamps, milliseconds and seconds are supported. The following timestamp identifiers are supported in the **Service URL** field:

- <start-epoch-ms>, <end-epoch-ms>. For example, `{"queryString":"exampleQuery","start":"<start-epoch-ms>", "end":"<end-epoch-ms>","isLive":false}`
- <start-epoch-s>, <end-epoch-s>. For example, `{"queryString":"exampleQuery","start":"<start-epoch-s>", "end":"<end-epoch-s>","isLive":false}`
- <start-`SimpleDateFormat`>, <end-`SimpleDateFormat`>. For example, `{"query": {"range": {"@timestamp": {"gte": "<start-yyyy-MM-dd'T'HH:mm:ss.SSSXXX>","lt": "<end-yyyy-MM-dd'T'HH:mm:ss.SSSXXX>"}}},"size": 10000}`

Custom mappings

Custom mappings allow more flexibility regarding timestamp settings. You must provide the mapping information about the timestamp field and how to parse the timestamp. Custom mappings support unnested JSON inputs.

The basic building blocks are similar to other integrations. The `rolling_time`, `instance_id_field`, `log_entity_types`, and `message_field` mappings are defined in the same way. For custom integrations, an extra `timestamp_settings` mapping needs to be specified. It contains the required `timestamp_field` to tell what field contains the timestamp, and two optional fields `pattern` and `multiplier`. The `pattern` field must be used when the timestamps must be parsed for a `String` representation, and the m`ultiplier` field must be used when the timestamp is represented as the `Double`type.

When timestamps are formatted correctly, as 13-digit UNIX® timestamps, you do not need to specify the `pattern` or `multiplier` fields. You need to define the `timestamp_field` field as in the following example:

```
{
    "rolling_time": 10
    "instance_id_field": "_app",
    "log_entity_types": "kubernetes.container_name",
    "message_field": "message",
    "timestamp_settings":{
      "timestamp_field":"_ts"
    }
{
```

Custom mapping with String type timestamps

When timestamps are represented as Strings, they must be parsed and converted to 13-digit UNIX timestamps. In this case, the `pattern` field must contain the parsing pattern. For example, if the timestamp is `2020-12-31 23:59:59 PST`, the integration mapping can be defined as follows:

```
{
    "rolling_time": 10,
    "instance_id_field": "_account",
    "log_entity_types": "kubernetes.container_name",
    "message_field": "_line",
    "timestamp_settings":{
      "timestamp_field":"_ts",
      "pattern": "yyyy-MM-dd hh:mm:ss z"
    }
}
```

Custom mapping with Double type timestamps

It might occur that timestamps are not represented in milliseconds. In this case, you must multiply or divide the input timestamps to obtain the milliseconds. The following example illustrates how you can use the `multiplier` field to obtain milliseconds.

Consider the following source timestamp without milliseconds:

```
{
   "_ts": 1569873609.539,
   "_account": "...",
   "_cluster": "...",
   "_host": "...",
   "_logtype": "...",
   "_line": "...",
   "_id": "...",
   "__key": "...",
}
```

You can set the `multiplier` field in the mapping to show the timestamps in milliseconds:

```
{
    "rolling_time": 10,
    "instance_id_field": "_account",
    "log_entity_types": "kubernetes.container_name",
    "message_field": "_line",
    "timestamp_settings":{
      "timestamp_field":"_ts",
      "multiplier": 1000
    }
}
```

Custom mapping with static instance ID support

You can input a static value for the `instance_id_field` in the IBM Cloud Pak for AIOps pipeline. See the following example:

```
{
   "rolling_time":10,
   "instance_id_field":"%aStaticInstanceId%",
   "log_entity_types":"kubernetes.container_name",
   "message_field":"_line",
   "timestamp_settings":{
```

```
      "timestamp_field":"_ts",
      "pattern":"yyyy-MM-dd hh:mm:ss z"
   }
}
```

The custom mapping places the value that is contained between `%...%` in the **`instance_id_field`** field throughout the IBM Cloud Pak for AIOps data collection. The following example illustrates the resulting data from the preceding custom mapping:

```
{
   "message":"exampleLogMessage",
   "instance_id":"aStaticInstanceId",
   "entities":{
      "pod":"examplePod",
      "_cluster":"exampleCluster",
      "container":"exampleContainer"
   },
   ...,
   "timestamp":1605195377154
}
```

Supported custom-mapping fields

Custom mapping fields

Field Name	Description	Default Value
rolling_time	The recurring time interval to capture data from in seconds.	10
instance_id_field	The field name in the incoming data that contains the application name.	kubernetes.namespace_name, kubernetes.host, kubernetes.container_name
log_entity_types	The field name in the incoming data that contains the entity to extract and analyze.	kubernetes.container_name
message_field	The field name in the incoming data that contains the log message.	`@rawstring`
standard_entity_types	Standardized fields. If declared, the performance for event grouping can be improved.	`None`
standard_entity_types .pod_name	Standardized field. If declared, the performance for event grouping can be improved.	`pod`
standard_entity_types .node_name	Standardized field. If declared, the performance for event grouping can be improved.	`node`
timestamp_settings	Customizable settings on timestamps from source's raw log output.	`None`
timestamp_settings.timestamp_field	The field name in the incoming data that contains the data's timestamp.	`_ts`
timestamp_settings.pattern (Optional)	Must be used when the timestamps must be parsed for a string representation. Custom integrations support `SimpleDateFormat` for timestamps in incoming data.	`yyyy-MM-dd hh:mm:ss z`
timestamp_settings.multiplier (Optional)	Used when epoch timestamps are represented as a double.	`None`

Enabling and disabling custom integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Custom** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section. Set **Data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

Your integration is now enabled or disabled. For more information about deleting a integration, see Deleting custom integrations.

Editing custom integrations

After you create your integration, you can edit the integration. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Custom** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Custom integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If you have not enabled or disabled your application, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling custom integrations. For more information about deleting a integration, see

Deleting custom integrations.

Deleting custom integrations

If you no longer need your custom integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before deleting your integration. For more information about disabling data collection, see Enabling and disabling custom integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Custom** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Custom integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating custom integrations using the integration SDK

You can create your own integration connectors to interact with IBM Cloud Pak for AIOps, such as for sending events, metrics, and topology data to IBM Cloud Pak for AIOps from an external source when a default integration is not available.

The framework for creating integration connectors is documented in the following repository, which also hosts the Java template for new custom integration connectors for IBM Cloud Pak for AIOps: IBM/cp4waiops-connectors-java-template. This template provides you with a working example for extending IBM Cloud Pak for AIOps. You can use this example as a starting base for developing your own custom integration. Details are included in the repository documentation to help you understand the framework architecture and to help you proceed from development to deployment.

The Java template uses the integration SDK, which can be obtained from Maven central. This SDK abstracts away the gRPC logic, provides security, and provides common methods to help you accelerate your custom integration development. Check Maven central for the latest version of the SDK before you create or update your custom integrations.

With the SDK and template, you can create your own integration connector for sending the following types of data to IBM Cloud Pak for AIOps:

- Events
- Metrics
- Topology

Creating dashboards using the dashboard extension toolkit

You can create your own dashboards to integrate with IBM Cloud Pak for AIOps, such as for summarizing alerts and incidents data with the IBM Cloud Pak for AIOps console.

A guide for creating dashboards is documented in the following repository, which also hosts dashboard examples for IBM Cloud Pak for AIOps: IBM/aiops-ui-extension-template. You can use these examples as a starting base for developing your own custom dashboards. Details are included in the repository documentation to help you understand the dashboard extension framework and to help you proceed from development to deployment.

Within dashboards created using the toolkit, you can leverage a vast variety of data from IBM Cloud Pak® for AIOps directly from the APIs. For more information, see APIs.

Creating Dynatrace integrations

A Dynatrace integration can provide metric, event, and topology data for the applications, services, process groups, and infrastructure that you monitor with Dynatrace. Multiple Dynatrace integration technologies are available. You need to have both an endpoint and an API Key ready. The AI Algorithms that analyze Dynatrace data are probable cause, and temporal correlation. Dynatrace SaaS 1.247 with v2 Metrics API is the version that is supported for the Dynatrace integration.

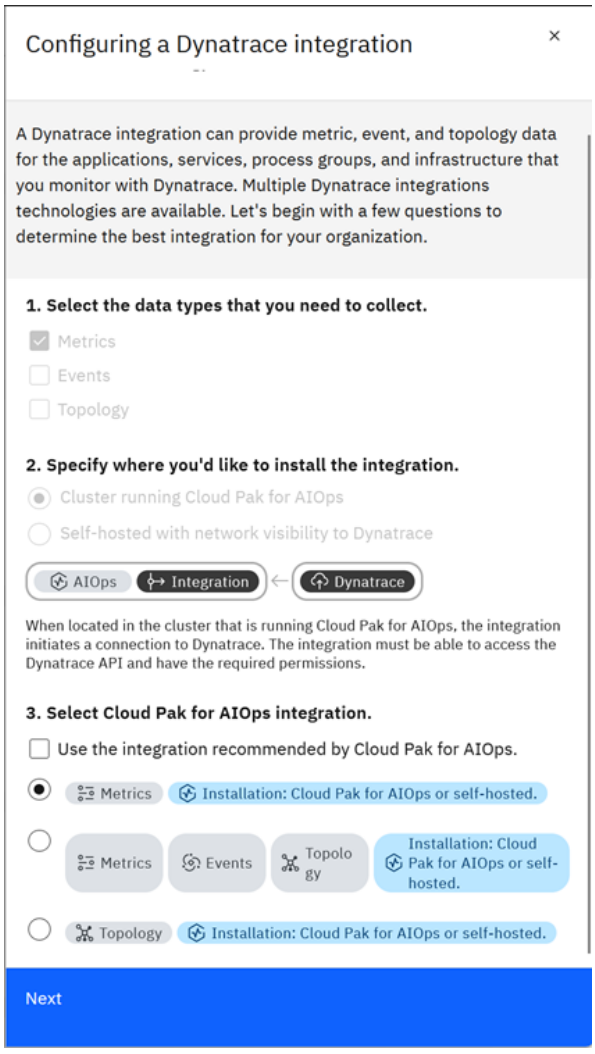
For more information about working with Dynatrace integrations, see the following sections:

- Creating Dynatrace integrations
- Enabling Dynatrace integrations
- Editing Dynatrace integrations
- Deleting Dynatrace integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating Dynatrace integrations

There are three data collection methods that can be used when creating Dynatrace integrations. The first method outlined here shows how to gather metric data only, while the second shows a new method of gathering both metric and event data together. Note that metric and event data collection is available only for technology preview, and is not for production usage. The third method is for collecting topology data.



- Method 1: Metric-only data collection
- Method 2: Metric, event, and topology data collection
- Method 3: Topology-only data collection

Method 1: Metric-only data collection

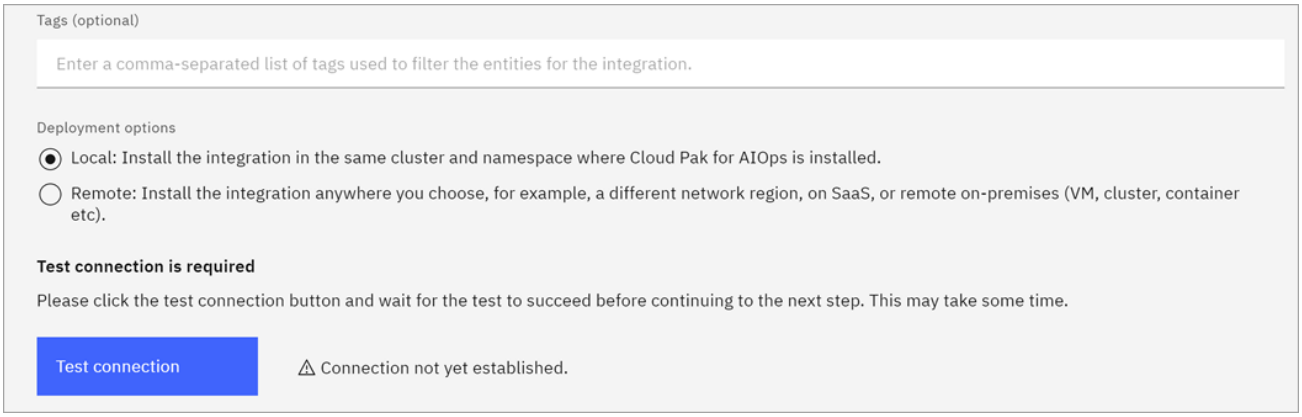
To create a Dynatrace integration, collecting metric data only, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of all integrations, find and click the **Dynatrace** tile.

   Note: If you do not immediately see Dynatrace, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section, or alternatively start typing *Dynatrace* in the search bar and the Dynatrace tile appears.
5. On the side-panel, review the instructions and select your required options from the following sections:
   - **Select the data types that you need to collect**: In this case select the *Metrics* checkbox, and not *Events* or *Topology*.
   - **Specify whether you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visability to Dynatrace* radio buttons.
   - **Select Cloud Pak for AIOps integration**: Deselect the **Use the integration recommended by Cloud Pak for AIOPs** checkbox.
   - Select the **Metrics** option at the top.

6. Then, click **Next**.

You see an *Overview*, further direction such as *what you need to have ready* and also *what AI algorithms analyze Dynatrace data* information.

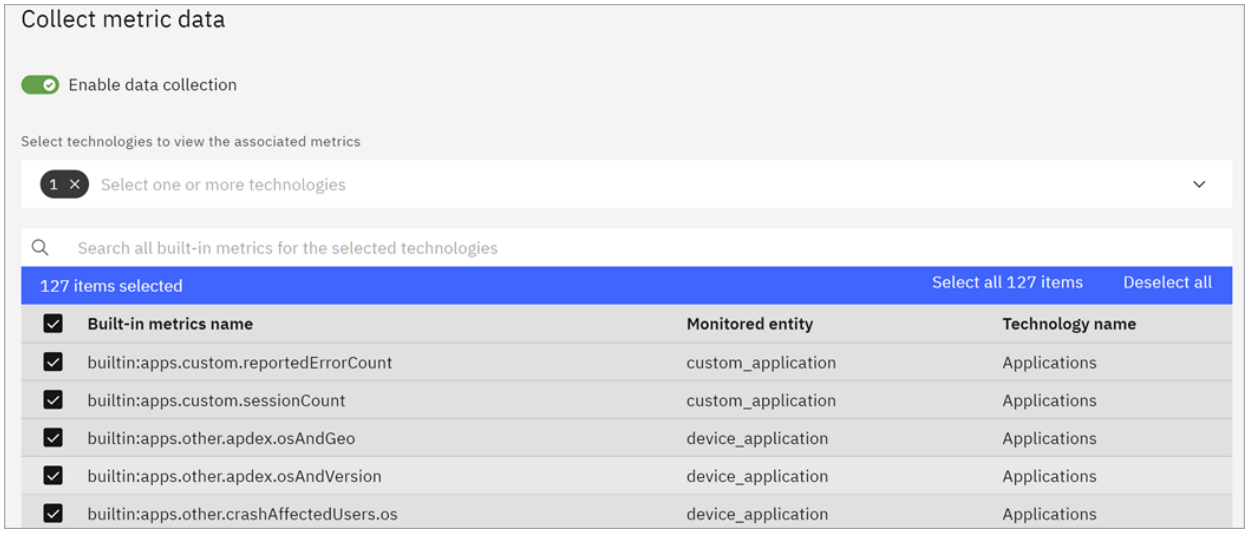


7. Click **Get Started**.
8. On the *Add integration* page, define the following general integration details:
   - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
   - **Description**: An optional description for the integration.
   - **Endpoint**: Dynatrace data source base url, for example `https://<your-environment-id>.live.dynatrace.com`.
   - **Access Token (API key)**: Enter an API key for the integration.

   - **Tags** (optional): Enter a comma-separated list of tags used to filter the entities for the integration.

     Note: It is recommended to configure *Tags* in order to collect data only for tags you are interested in.
   - **Deployment options**: Select between *Local* and *Remote* radio buttons.
     - Local: Install the integration in the same cluster and namespace where Cloud Pak for AIOps is installed.
     - Remote: Install the integration anywhere you choose, for example in a different network region, on SaaS, or remote on-premises (VM, cluster, container, and so on).

       Note: If you select *Remote*, you are be provided with a remote deployment script to establish your integration after adding it.
9. To verify the SSL/TLS configuration:
   1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
   2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.
10. Click **Test connection**. It is best to wait for the test to succeed before continuing to the next step. This can take some time.



11. Click **Next**.
12. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to Dynatrace via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server. **Note:** The URL for the metrics-only integration should have the protocol in the URL.
    - **Port number of proxy server**: Enter a port. The default is 8080.

Note: Only unauthenticated HTTP proxy is supported.

13. Click **Next**.
14. Enter the following *Collect metric data* to define how you want to collect metric data:
    - **Enable data collection**: Set the *Enable data collection* toggle button to *on*.
    - **Select technologies to view the associated metrics**: From this dropdown menu you can click the *Select all technologies* checkbox, or pick and choose technologies from the list as you need. You then see a list of all built-in metrics names for the options you selected. You can leave all checked or pick and choose from the list by clicking in the respective checkbox to deselect particular metrics for a technology. It is recommended to only select the metrics that are needed.

    - **Aggregation intervals (minutes)**: The frequency at which data is collected. The default is 5.
    - **Only collect live data once the integration is established**: Click this checkbox if you want to only collect live data, as you are not be able to collect historical data after live data collection has started. If unchecked you are able to collect historical data.

      Note: The recommended time period for collecting historical metric data is two weeks. You can collect up to 31 days of historical data so your start date should not exceed 31 days from the present. If the end date is not specified, Cloud Pak for AIOps collects historical data from the specified start date and continue with live data collection. You are not be able to collect historical data after live data collection has started.
    - **Start date**: Enter in the format *mm/dd/yyyy*.
    - **Start time**: Enter in the format *hh:mm*.
    - **Timezone**: Set to local time.
    - **Add End Date**: click the *Add End Date* button if you want to set an end date.
15. Click **Done**.

Note: The API limit can cause a delay in receiving metrics from Dynatrace. Each Dynatrace token is limited to 50 API requests per minute. Multiple API requests might be needed for each metric data collection interval based on the amount of data that Dynatrace returns. If the required requests to the API exceed the limit, the metrics-only integration throttles the requests until more requests are available in the next minute. Review the performance considerations for metric integrations and the filtering options available to optimize this behavior. For more information, see Performance considerations for metric data collection.

A message appears to indicate that the integration is complete, and that IBM Cloud Pak for AIOps has successfully created your Dynatrace integration and will start collecting data shortly.

Method 2: Metric, event, and topology data collection

To create a Dynatrace integration collecting metric and event data together, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.

2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of all integrations, find and click the **Dynatrace** tile.

   Note: If you do not immediately see Dynatrace, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section, or alternatively start typing *Dynatrace* in the search bar and the Dynatrace tile appears.

5. On the side-panel, review the instructions and select your required options from the following sections:

   - **Select the data types that you need to collect**: Select the relevant checkbox from *Metrics*, *Events*, or *Topology*, which in this case is *Metrics*, *Events* or *Topology*.
   - **Specify whether you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visability to Dynatrace* radio buttons.
   - **Select Cloud Pak for AIOps integration**: You can leave this at the recommended default *Use the integration recommended by Cloud Pak for AIOps*, which collects both metric and event data.

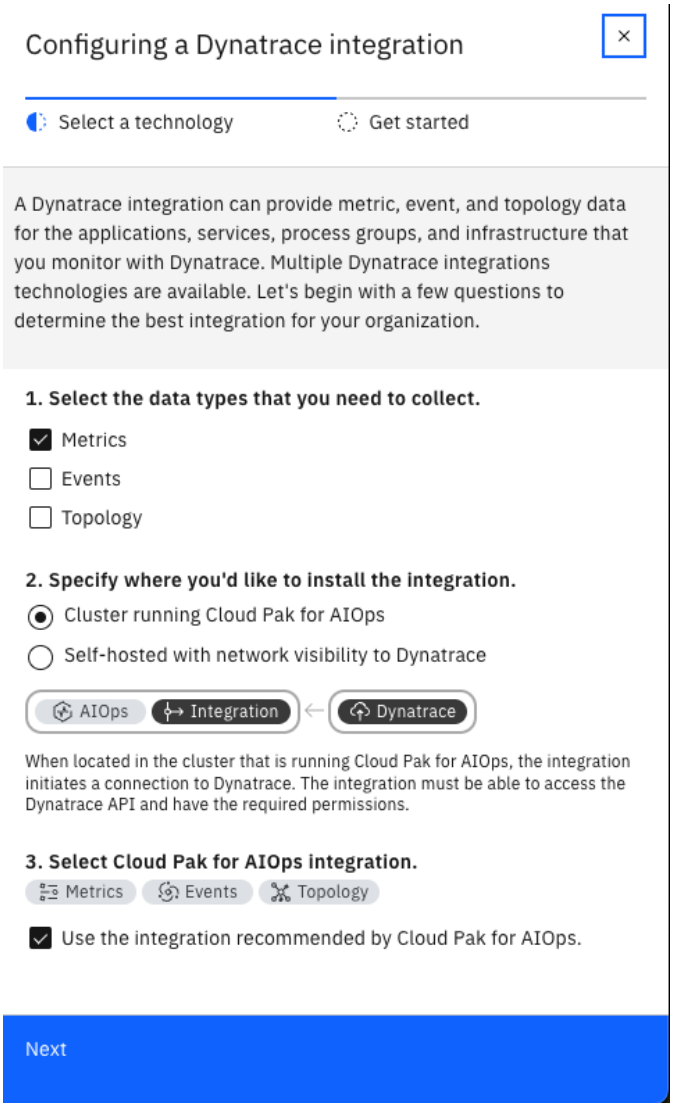


Figure. Metric selected

   Important: Depending on which of the data types that you choose to collect the following sections vary. This integration does not support historical data collection. However it is worth noting that if did select *Topology* you would be brought to a *New observer job* page. Using the Dynatrace observer, you can query a specified Dynatrace environment for information about its applications, services, process groups, and infrastructure entities. For more information, see Configuring a Dynatrace Observer job.

6. Then, click **Next**.

   You see an *overview*, further direction such as *what you need to have ready* and also *what algorithms analyze Dynatrace data* information.

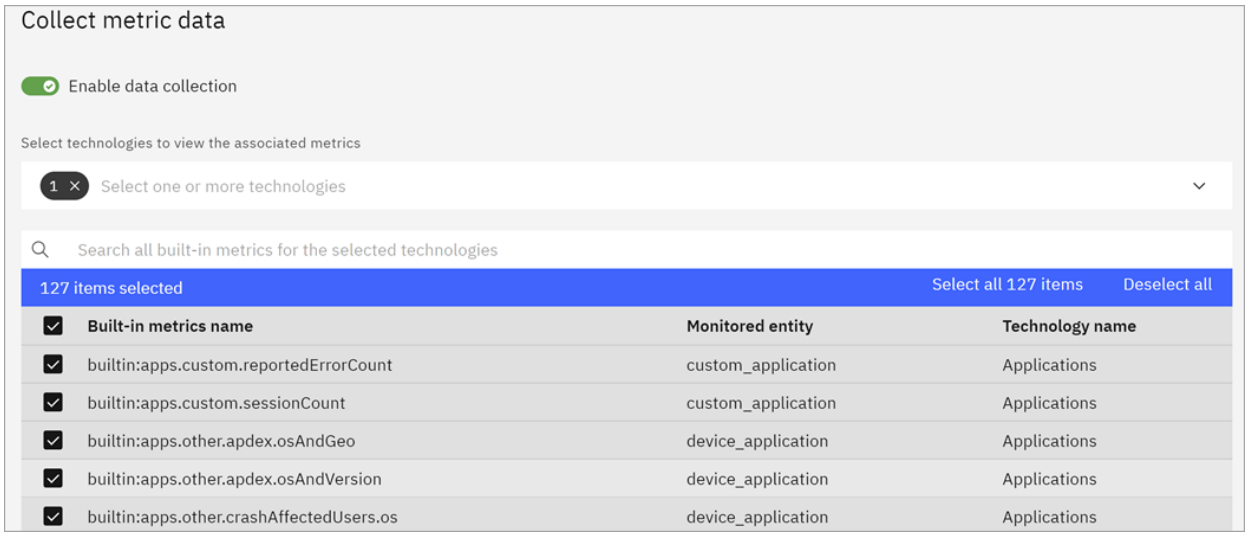
7. Click **Get Started**.
8. On the *Add integration* page, define the following general integration details:

   - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.

- **Description**: An optional description for the integration.
- **Endpoint**: Dynatrace data source base url, for example **`https://<your-environment-id>.live.dynatrace.com`**.
- **Dynatrace zone** (optional): Enter a single Dynatrace zone to monitor for the integration.
- **Tags** (optional): Enter a comma-separated list of tags used to filter the entities for the integration.

  Note: It is recommended to configure one of either *Dynatrace zone* or *Tags* in order to collect data only for tags or management zones you are interested in.
- **Deployment options**: Select between *Local* and *Remote* radio buttons.
  - Local: Installs the integration in the same cluster and namespace where Cloud Pak for AIOps is installed.
  - Remote: Installs the integration anywhere you choose, for example, a different network region, on SaaS, or remote on-premises (VM, cluster, container, and so on) and enter a name in the **Installation name** field.

    Important: Podman must be installed to execute the remote deployment script with a recommended minimum version of 4.4.1. Read and write access is required for the folder where the remote deployment script is executed and the script also must have execution permissions in order to be run. No more than one remote deployment script should be executed per host.



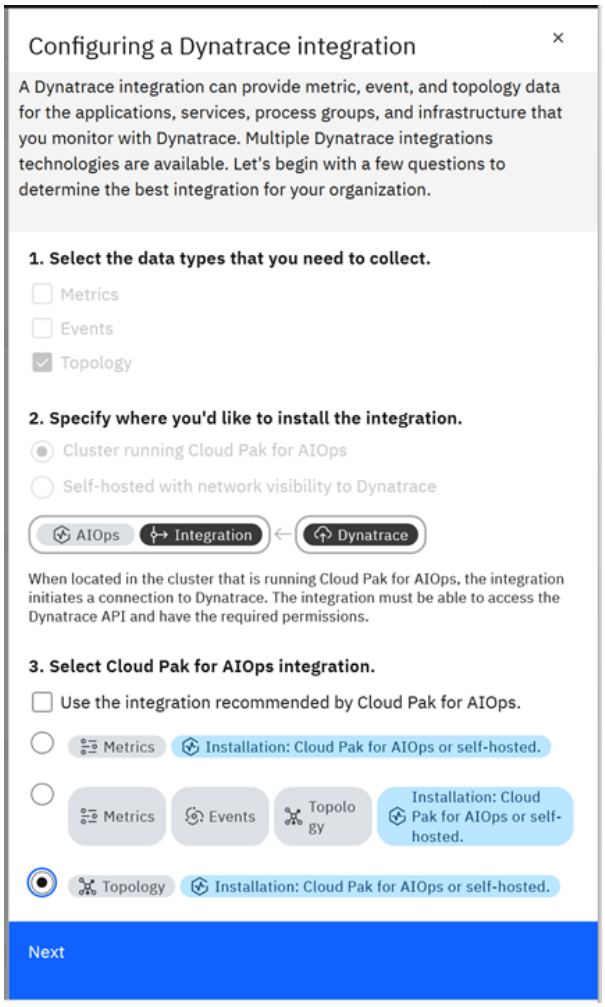
9. Click **Next**.
10. On the *Authentication* page, define the following general integration details:
    - **Authentication**: Select between the *Hashicorp Vault* and *Access token (API key)* radio buttons.

    If you select *Access token (API key)* you need to enter an API key for the integration, and if you select *Hashicorp Vault* you need to complete the following fields:

    - **Endpoint (URL)**: Endpoint URL of the Hashicorp Vault server instance.
    - **HashiCorp Vault access token**: Enter a Hashicorp Vault access token for this integration.
    - **HashiCorp Vault secret path**: Enter a Hashicorp Vault secret path for this integration.
    - **CA HTTPS Certificate**: Enter a CA certificate used for HTTPS with Hashicorp Vault.
    - **HashiCorp Vault secret refresh rate**: The HashiCorp Vault secret is refreshed automatically at a fixed hourly interval. The default refresh rate is every 24 hours.

      Note: Only HTTPS for Vault is supported, and not HTTP.
11. Click **Next**.
12. Enter the following *Collect metric data* (optional) to define how you want to collect metric data:
    - **Enable data collection**: Set the *Enable data collection* toggle button to *on*.
    - **Select technologies to view the associated metrics**: From this dropdown menu you can click the *Select all technologies* checkbox, or pick and choose technologies from the list as you need. You then see a list of all built-in metric names for the options you selected. You can leave all checked or pick and choose from the list by clicking in the respective checkbox to deselect particular metrics for a technology. It is recommended to only select the metrics that are needed.
    - **Polling interval (seconds)**: The frequency at which data is collected (in seconds). The default value is 300.

13. Click **Next**.
14. Enter the following *Collect event data* (optional) to define how you want to collect event data:
    - **Enable data collection**: Set the *Enable data collection* toggle button to *on*.
    - **Select technologies to view the associated events**: From this dropdown menu you can click the *Select all technologies* checkbox, or deselect this, and pick and choose from the list as you need. You then see a list of *Event names* for the technologies you selected. You can leave all checked or pick and choose from the list by clicking in the respective checkbox. It is recommended to only select the events that are needed.
    - **Polling interval (seconds)**: The frequency at which data is collected (in seconds). The default value is 60.
15. Click **Done**.



A message appears to indicate that the integration is complete, and that IBM Cloud Pak for AIOps has successfully created your Dynatrace integration and will start collecting data shortly.

Method 3: Topology-only data collection

To create a Dynatrace integration, collecting topology data, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of all integrations, find and click the **Dynatrace** tile.

   Note: If you do not immediately see Dynatrace, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section, or alternatively start typing *Dynatrace* in the search bar and the Dynatrace tile appears.
5. On the side-panel, review the instructions and select your required options from the following sections:
    - **Select the data types that you need to collect**: In this case select the *Topology* checkbox.
    - **Specify whether you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visability to Dynatrace* radio buttons.
    - **Select Cloud Pak for AIOps integration**: Deselect the **Use the integration recommended by Cloud Pak for AIOPs** checkbox.
    - Select the **Topology** option at the bottom.

6. Then, click **Next**.

   You see an *Overview*, further direction such as *what you need to have ready* and also *what AI algorithms analyze Dynatrace data* information.

7. Click **Get Started**.

8. On the *Add integration* page, define the following general integration details:

   - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
   - **Description**: An optional description for the integration.
   - **Endpoint**: Dynatrace data source base url, for example `https://<your-environment-id>.live.dynatrace.com`.
   - **Dynatrace zone** (optional): Enter a single Dynatrace zone to monitor for the integration.
   - **Tags** (optional): Enter a comma-separated list of tags used to filter the entities for the integration.

     Note: It is recommended to configure one of either *Dynatrace zone* or *Tags* in order to collect data only for tags or management zones you are interested in.

   - **Deployment options**: Select between *Local* and *Remote* radio buttons.
     - Local: Installs the integration in the same cluster and namespace where Cloud Pak for AIOps is installed.
     - Remote: Installs the integration anywhere you choose, for example, a different network region, on SaaS, or remote on-premises (VM, cluster, container, and so on) and enter a name in the **Installation name** field.

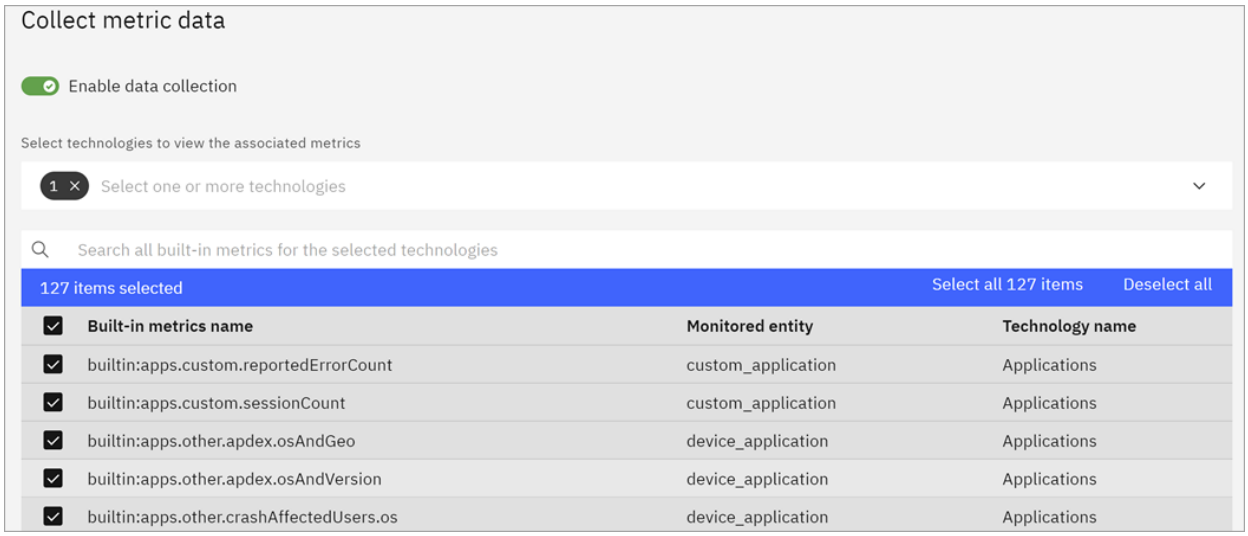
       Important: Podman must be installed to execute the remote deployment script with a recommended minimum version of 4.4.1. Read and write access is required for the folder where the remote deployment script is executed and the script also must have execution permissions in order to be run. No more than one remote deployment script should be executed per host.

9. Click **Next**.

10. On the *Authentication* page, define the following general integration details:

    - **Authentication**: Select between the *Hashicorp Vault* and *Access token (API key)* radio buttons.

If you select *Access token (API key)* you need to enter an API key for the integration, and if you select *Hashicorp Vault* you need to complete the following fields:



- **Endpoint (URL)**: Endpoint URL of the Hashicorp Vault server instance.
- **HashiCorp Vault access token**: Enter a Hashicorp Vault access token for this integration.
- **HashiCorp Vault secret path**: Enter a Hashicorp Vault secret path for this integration.
- **CA HTTPS Certificate**: Enter a CA certificate used for HTTPS with Hashicorp Vault.
- **HashiCorp Vault secret refresh rate**: The HashiCorp Vault secret is refreshed automatically at a fixed hourly interval. The default refresh rate is every 24 hours.

  Note: Only HTTPS for Vault is supported, and not HTTP.

11. Click **Next**.
12. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to Dynatrace via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server. **Note:** The URL for the metrics-only integration should have the protocol in the URL.
    - **Port number of proxy server**: Enter a port. The default is 8080.

13. Click **Next**.
14. Enter the following *Collect metric data* (optional) to define how you want to collect metric data:
    - **Enable data collection**: Set the *Enable data collection* toggle button to *on*.
    - **Select technologies to view the associated metrics**: From this dropdown menu you can click the *Select all technologies* checkbox, or pick and choose technologies from the list as you need. You then see a list of all built-in metric names for the options you selected. You can leave all checked or pick and choose from the list by clicking in the respective checkbox to deselect particular metrics for a technology. It is recommended to only select the metrics that are needed.
    - **Polling interval (seconds)**: The frequency at which data is collected (in seconds). The default value is 300.

15. Click **Next**.
16. Enter the following *Collect event data* (optional) to define how you want to collect event data:
    - **Enable data collection**: Set the *Enable data collection* toggle button to *on*.
    - **Select technologies to view the associated events**: From this dropdown menu you can click the *Select all technologies* checkbox, or deselect this, and pick and choose from the list as you need. You then see a list of *Event names* for the technologies you selected. You can leave all checked or pick and choose from the list by clicking in the respective checkbox. It is recommended to only select the events that are needed.
    - **Polling interval (seconds)**: The frequency at which data is collected (in seconds). The default value is 60.
17. Click **Next**.
18. Enter the following *Collect topology data* (optional) to define how you want to collect topology data:
    - **Enable data collection**: Set the *Enable data collection* toggle button to *on*.
    - **Cloud Pak for AIOps topology entity selector**: This mapping configures the entities and filters used to ingest topology data from Dynatrace to Cloud Pak for AIOps. The entity selector from the Observer Jobs UI can be used in this field.
    - **Data collection mode**: Select between the **Collect topology data continuously at a specified time interval** and **Collect topology data once** radio buttons.
    - **Schedule topology data collection**: Select between the **Start data collection after creating the integration** and **Start data collection at a scheduled date and time** radio buttons.
    - **Time interval of data collection**: Specify how frequently to run the topology data collection.
    - **Unit of time**: Specify the unit of time for topology data collection.
    - **Number of records to be fetched per page**: Specify a value between 100 and 4000. The default value is 4000.
    - **Cloud Pak for AIOps topology edge mapping** (optional): This mapping defines the relationship between the Cloud Pak for AIOps topology edges and Dynatrace. Cloud Pak for AIOps will use a default mapping for edges by default, but edge mapping values can be overrided in this field.
    - **Cloud Pak for AIOps entity mapping** (optional): This mapping defines the relationship between the Cloud Pak for AIOps topolopy entities and Dynatrace entity types. Cloud Pak for AIOps will use a default mapping for the entity relationship by default, but the entity types can be overrided in this field.
    - **Grouping vertex preference** (optional): Cloud Pak for AIOps will create a defined topology for the discovered vertices. By default, there is no grouping vertex preference.
    - **Connection timeout** (optional): The connection timeout for the topology collection in milliseconds. The default is 5000 milliseconds.
    - **Access scope** (optional): The access scope provides the scope for the topology resources. The access scope can be used to aid the mapping of alerts to resources when resources in different scopes share the same matchTokens. Examples of scope would be locations, project names, or namespaces.
19. Click **Done**.

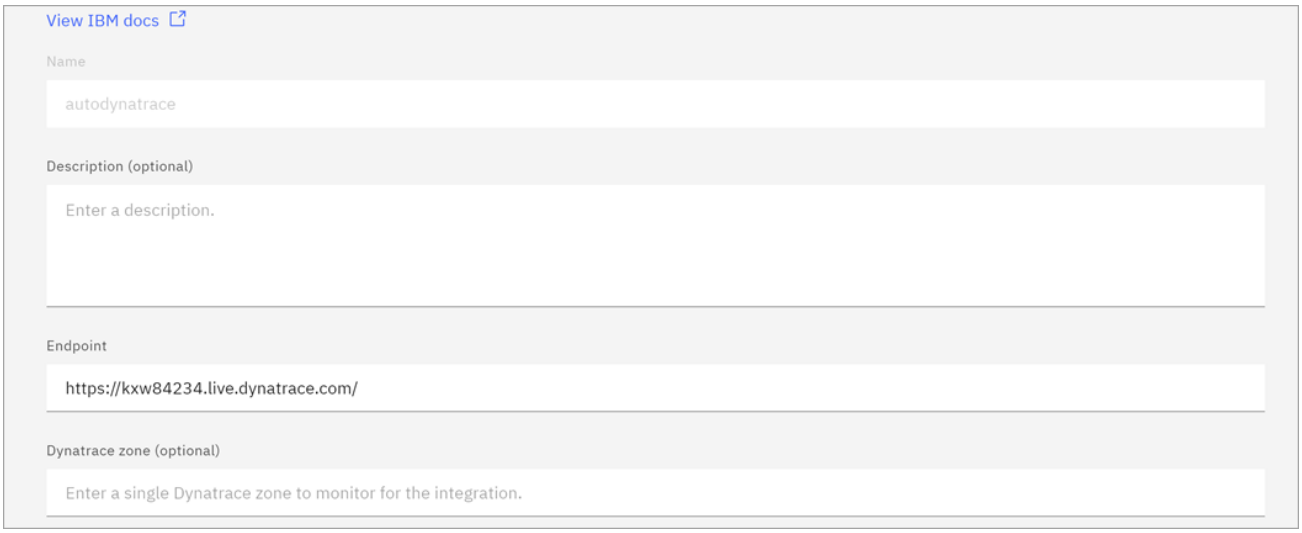
A message appears to indicate that the integration is complete, and that IBM Cloud Pak for AIOps has successfully created your Dynatrace integration and will start collecting data shortly.

Known issue

There is currently a known issue with the Dynatrace metrics, events, and topology integration whereby the events will show up outside of the management zone if a management zone filter is applied. As a workaround, you should use a *tags* filter. The management zone filtering for metrics is not affected.

Enabling and disabling Dynatrace integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:



1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Dynatrace** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect metric data* section for the metrics-only Dynatrace integration, or indeed for the combined events and metrics integration go to both the *Collect metric data* and *Collect event data* sections. Set **Enable data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting an integration, see Deleting Dynatrace integrations.

Editing Dynatrace integrations

After you create your integration, your can edit the integration by completing the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Dynatrace** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Dynatrace integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Dynatrace integrations. For more information about deleting an integration, see Deleting Dynatrace integrations.

Known issue with the Dynatrace integration

When event data collection is disabled and metrics data collection is enabled you may see errors in the logs, but it will not affect data collection.

Deleting Dynatrace integrations

If you no longer need your Dynatrace integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Dynatrace** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Dynatrace integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**, or alternatively click the dustbin icon.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating ELK integrations

Elasticsearch, Logstash, and Kibana (ELK) integrations provide log data for anomaly detection in IBM Cloud Pak® for AIOps. An ELK integration provides log data, which is used to establish a baseline of normal behavior and then identify anomalies. These anomalies can be correlated with other alerts and events, and published to your ChatOps interface to help you determine the cause and resolution of a problem.

For more information about working with ELK integrations, see the following sections:

- Creating ELK integrations
- Enabling ELK integrations
- Editing ELK integrations
- Deleting ELK integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

About this task

Before creating the integration, you should be aware of the following information.

- **Load**: To prevent this integration placing an inordinate load on your data source and potentially impacting your logging operations, this integration only connects to one API with a default data frequency of 60 seconds. This is controlled by using the **Sampling rate** setting in the Procedure section.
- **Access**: Custom data sources are cloud-based REST APIs. Access is configured by using the authentication methods that are specified in the **Authentication type** setting in the Procedure section.
- **Data volume**: Data volume depends on the application, and is not a set value. Therefore, it does not appear in the settings.

Known issue with later versions of ELK

IBM Cloud Pak for AIOps only supports ELK up to version 7.12.0. For later versions of ELK, the **`event_link`** provided by AIOps does not open the correct logs in Kibana.

The reason for this incorrect link is that later versions of ELK use the **`uuid`** as the default ID for the index pattern. As a workaround, you must set the Custom index pattern ID to same value as the index pattern name.

To do so, use the following steps:

1. Log in to the ELK instance.
2. From the hamburger menu, navigate to **Stack Management**.
3. Click on **Create index pattern**.
4. Complete the required details.
5. Click on the **Show advanced settings button**.
6. Set the **Custom index pattern ID** to the same value that you specified for the **Index pattern name**. This will override the default value.

Procedure

To create an ELK integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **ELK** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.

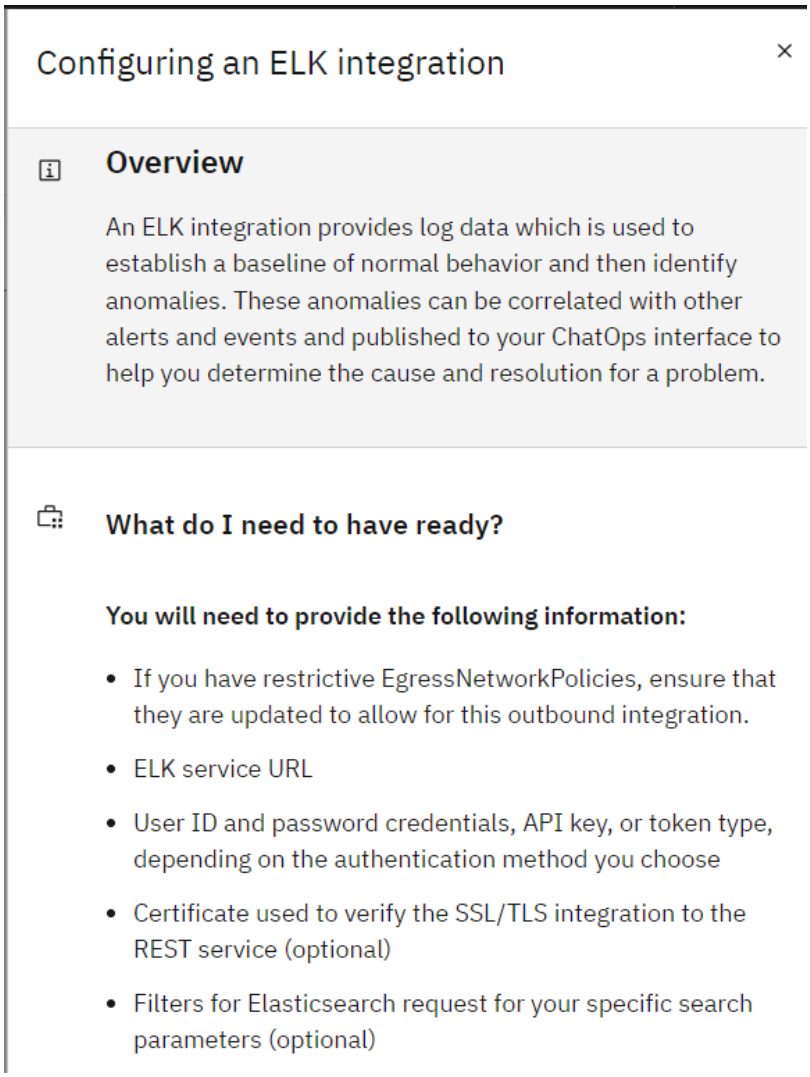


Figure. Configure ELK integration

5. On the side-panel, review the instructions and when ready to continue, click **Get started**.

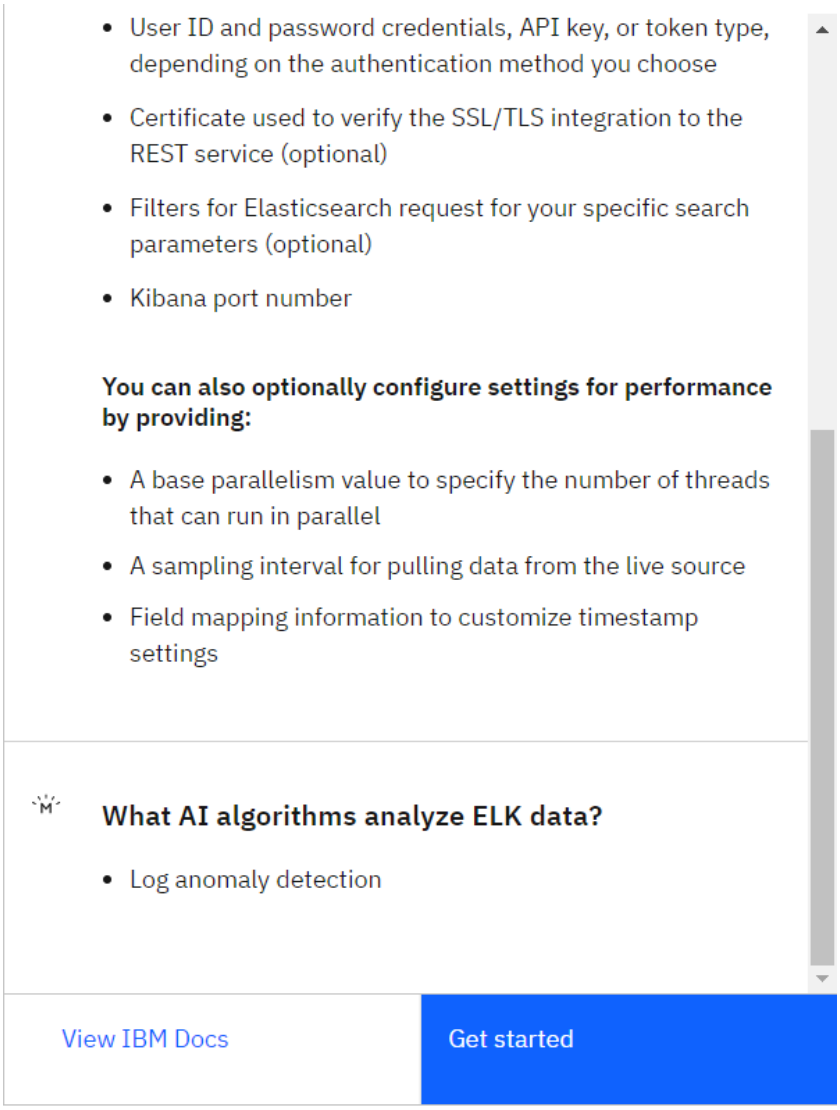

Figure. Configure ELK integration - get started

6. On the *Add integration* page, define the general integration details:

   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **ELK service URL**: ELK service URL: The Elasticsearch host and public API port. The URL must have the target index that IBM Cloud Pak for AIOps uses to search for the data from your applications. If you want to use all data, specify `*` as your index. For example, your ELK service URL can be `https://myURL.com:8080/*`.
   - **Kibana URL**: Enter a URL for the service instance.

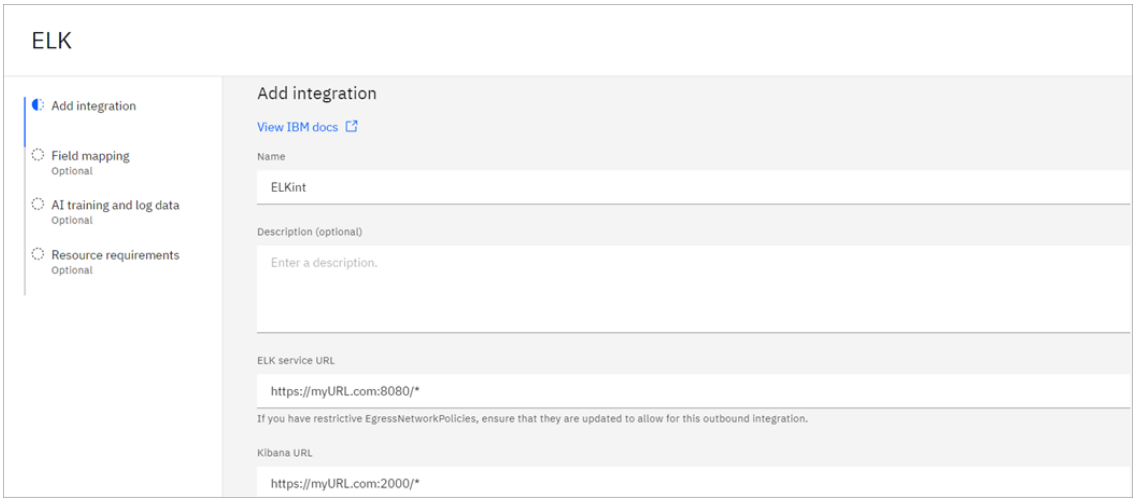

Figure. Create ELK integration

- **Authentication type**: Select one of the following values:
  - **User ID/password**: The Elasticsearch instance has a user ID and password as authentication. You must enter both in the integration configuration.
  - **API key**: The Elasticsearch instance is authenticated with an API key.
  - **Token**: The Elasticsearch instance is authenticated with a temporary token.
  - **Custom**: The Elasticsearch instance is authenticated with a header and value.
  - **None**: The Elasticsearch instance has no authentication.

    Note: If you selected API key as Authentication type value, then you need to follow the steps on ELK integration steps to use ApiKey authentication method.
- **User ID**: Enter a user ID for the integration.
- **Password**: Enter a password for the integration.
- **Certificate (optional)**: Certificate used to verify the SSL/TLS connection to the REST service.
- **Filters (optional)**: A custom Boolean Query to filter the Elasticsearch request for your specific application, terms, keywords, or other filters.
- **Time zone (optional)**: The time zone in which your data is situated. The default time is converted from the system time relative to UTC time. The default value is UTC.
- **Kibana port**: The port of the Kibana instance that is on the same host as the Elasticsearch instance. If the Kibana instance is not exposed on the default `5601` port, change this value to the port where the Kibana instance is shown.
- **Base parallelism**: Select a value to specify the number of Flink jobs that can run in parallel. These jobs run to process and normalize the collected data. The default value is 1. However, it is recommended to use a higher value than 1 so that you can process data in parallel. This value cannot exceed the total available free Flink slots. In a small environment, the available flinks slots are 16, while in a large environment, the maximum available slots are 32. If you are collecting historical data with this integration, you can set this value to be equal to the **source** parallelism.
- **Sampling rate**: The rate at which data is pulled from live source (in seconds). The default value is `60`.
- **JSON processing option**: Select a JSON processing option.
  - **None**: The default option. The JSON is not processed or modified.
  - **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
  - **Filter**: This option extracts the JSON object and replaces it with an empty string.
  - For more information about the options, see Managing embedded JSON.

Note: To improve data throughput, you can increase the base parallelism value incrementally. For more information about maximum base parallelism for starter and production deployments, see Improving data streaming performance for log anomaly detection.

Note: If using the Filter option, you should not use a timestamp in the filter query. It gives a parsing error in the backend.

```
    "range": {
      "@timestamp": {
        "gte": "now-2m",
        "lt" : "now"
      }
```

Other than that, ELK filter can use any clauses so long as the fields and the values that are specified in the filter are relevant to the target endpoint data set.

Filter debugging tip: You can first test the filter by using the curl command to ELK endpoint. When using the curl command, the timestamp range is optional in the elk filter, and depends on whether you want to narrow down the search over a particular period of time. If the query gets zero records with 200 HTTP responses (for example no filter error), it is an indication that the query was not able to hit the particular set of data scoped by the filter. Users can tune filter to get the needed results.

7. You test your integration by clicking **Test connection**.
8. Click **Next**.
9. Enter *Field Mapping* information (Optional):

   You can improve search performance by mapping the fields from your implementation fields to IBM Cloud Pak for AIOps's standard fields. For more information about how field mappings are defined, see Mapping data from incoming sources. For more information about using mappings to clean your data for use in IBM Cloud Pak for AIOps, see Cleaning mapped data that use regular expressions. Consider the supported data schema when you create your field mapping:

```
{
  "codec": "elk",
  "rolling_time": 10,
  "instance_id_field": "application_name",
  "log_entity_types": "kubernetes.pod_name",
  "message_field": "message",
  "timestamp_field": "@timestamp",
  "resource_id": "kubernetes.pod_name"
}
```

10. Click **Next**.

11. Enter AI training and log data (Optional):

    Select how you want to manage collecting data for use in AI training and anomaly detection. Click the **Data collection** toggle to turn on data collection, then select how you want to collect data:

    - **Live data for continuous AI training and anomaly detection**: A continuous collection of data from your integration is used to both train AI models and analyze your data for anomalous behavior.

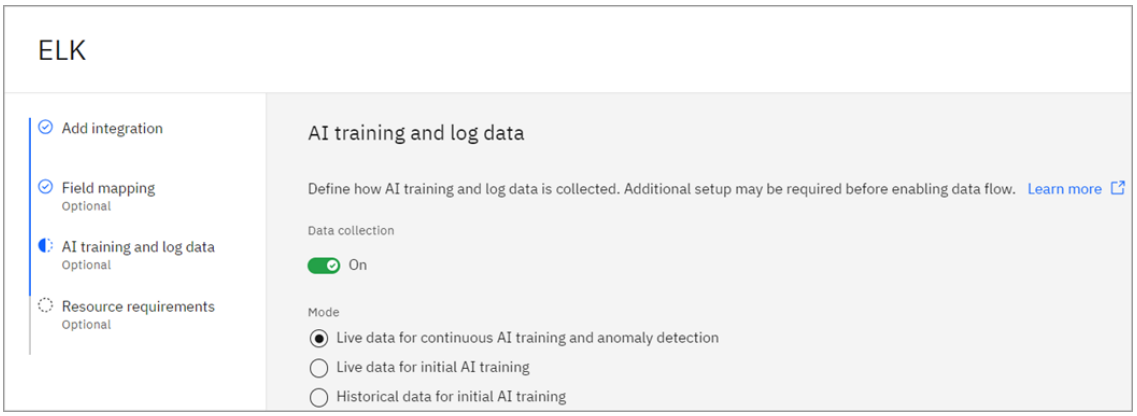

Figure. AI training

    Note: After an initial installation, there is no data at all in the system. If you select this option, then the two different log anomaly detection algorithms behave in the following ways:

    - Natural language log anomaly detection does not initially detect anomalies as no model has been trained. You can retrieve historical data (select **Historical data for initial AI training**) to speed up the retrieval of data to train on, or you can leave the **Live data for continuous AI training and anomaly detection** setting on. In the latter case, the system gathers training data live and after a few days there is enough data to train a model. When this model is deployed, then it detects anomalies as normal.

    - Statistical baseline log anomaly detection does not detect anomalies for the first 30 minutes of data collection. This is because it does not have a baseline yet. After 30 minutes of live data collection the baseline is automatically created. After that it detects anomalies on an ongoing basis, while continuing to gather data and improve its model every 30 minutes.

    - **Live data for initial AI training**: A single set of training data used to define your AI model. Data collection takes place over a specified time period that starts when you create your integration.

      Note: Selecting this option causes the system to continue to collect data while the option is enabled; however, the data is collected for training only, and not for log anomaly detection. For more information about AI model training, including minimum and ideal data quantities, see Configuring AI training.

    - **Historical data for initial AI training**: A single set of training data used to define your AI model. You need to give Start and End dates, and specify the parallelism of your source data. Historical data is harvested from existing logs in your integration over a specified time period in the past.

      - **Start date**: Select a start date from the calendar and enter the time in hh:mm (hours and minutes) format.

        Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.

      - **Time zone**: Select your time zone from the dropdown list.

      - **End date and time**: Click **Add end date** and select an end date from the calendar and enter the time in hh:mm format.

        Note: If you do not specify the end date, then live data collection follows the historical data collection. If you do not want to set an end date, click **Remove end date**.

      - **Source parallelism (1-50)**: Select a value to specify the number of requests that can run in parallel to collect data from the source. Generally, you can set the value to equal the number of days of datat that you want to collect. When you are setting this value, consider the number of requests that are allowed by the source in a minute. For example, if only 1-2 requests are allowed, set the value to be low.

    Important: Keep in mind the following considerations when you select your data collection type:

    - Anomaly detection for your integration occurs if you select *Live data for continuous AI training and anomaly detection*.

    - Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.

12. Click **Next**.

13. On the *Resource requirements* page, you can review the slot usage for your log integrations to see if there are enough slots to fully support the integration for multizone high availability.

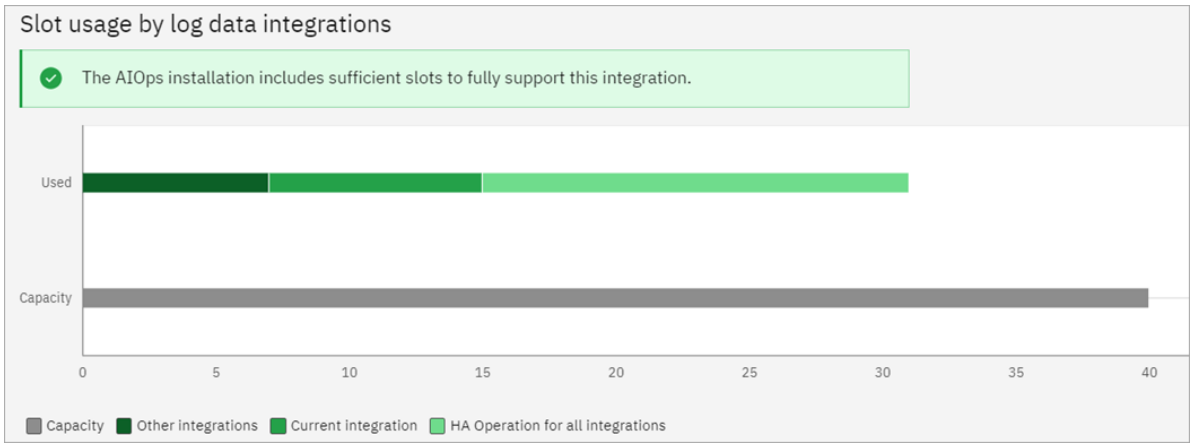

Figure. Resource requirements

If you set the **Data collection** toggle to **On**, you will see the resource management overview.

- If your current usage and other usage are less than the provisioned slots, but the HA slots exceed the provisioned slots, you will be able to create the integration, but will see a warning that you do not have enough slots. The integration will not have multizone high availability.
- If your projected usage exceeds the provisioned slots, you will not be able to create the integration because you do not have enough slots on your system for log data integrations.
- If your total slots, including HA slots, are within the provisioned slots, the integration will have multizone high availability.

  Note: HA operation assumes high availability for three zones.

If you set the **Data collection** toggle to **Off**, you will see a message stating that you need to enable logs data collection to see the resource management overview. When data collection is off, no slots are used by that integration.

14. Click **Done**.

You created an ELK integration in your instance. After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling ELK integrations.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Enabling and disabling ELK integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **ELK** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section. Set **Data integration** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting ELK integrations.

Editing ELK integrations

After you create your integration, your can edit the integration. For example, if you specified *Historical data for initial AI training* but now want your integration to pull in live data for continuous monitoring, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **ELK** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the ELK integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling ELK integrations. For more information about deleting a integration, see

Deleting ELK integrations.

Deleting ELK integrations

If you no longer need your ELK integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before deleting your integration. For more information about disabling data collection, see Enabling and disabling ELK integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **ELK** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the ELK integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Generating an API Key for an ELK integration

When you are creating an ELK integration, you might need to generate an API key. Use the following procedure to generate the API Key.

Procedure

When you are completing these steps, replace the cluster and API key details with the details for your environment.

1. To check, or list, your existing **api_key**, run the following command:

   ```
   curl -k -X GET 'https://was911.myibm.com:9200/_security/api_key' -H 'Authorization: Basic ZWxhc3RpYzpwYXNzdzByZA==' | jq '.'
   ```

2. If you need to create an **api_key**, run the following command:

   ```
   curl -k -X POST 'https://was911.myibm.com:9200/_security/api_key' -H 'Content-Type: application/json' -H 'Authorization: Basic ZWxhc3RpYzpwYXNzdzByZA==' -d '{ "name": "my-api-key-sheikh-2", "role_descriptors": {} }' | jq '.'
   ```

3. Create the **encoded-base64-api-key** with the following command. Keep **"id": "LoRMmn4BCbCvoljFvMzq"** and **"api_key": "ZZEnRG93Q1i6wOCVW2XWug"**. These settings are needed to create the **encoded-base64-api-key**.

   ```
   echo -n "{id}:{api_key}" | base64
   ```

   For example, see the following example:

   ```
   echo -n "LoRMmn4BCbCvoljFvMzq:ZZEnRG93Q1i6wOCVW2XWug" | base64
   TG9STW1uNEJDYkN2b2xqRnZNenE6WlpFblJHOTNRMWk2d09DVlcyWFd1Zw==
   ```

4. Test the ELK query by using the **encoded-base64-api-key**:

   ```
   curl -k -X 'GET' 'https://was911.myibm.com:9200/my-index' -H 'accept: /' -H 'Authorization: ApiKey {encoded-base64-api-key}}'
   ```

5. Test the key with the IBM Cloud Pak for AIOps console:

   1. Create an ELK integration with **api_key** as **encoded-base64-api-key**.
   2. Test the integration.
   3. Turn on data collection and save.
   4. Finally, ensure that your integration is saved.

Creating Elasticsearch, Fluentd, and Kibana (EFK) integrations

You can connect to, and use, an Elasticsearch, Fluentd, and Kibana (EFK) stack as a log aggregator tool for IBM Cloud Pak for AIOps.

EFK is a suite of tools that functions as a log aggregation tool. Similar to an Elasticsearch, Logstash, and Kibana (ELK) integration with this type of integration, you can collect log data to establish a baseline of normal behavior and then identify anomalies. These anomalies can be correlated with other alerts to help you determine the cause and resolution of a problem.

You can connect to an Elasticsearch, Fluentd, and Kibana (EFK) stack as a variant option to connecting to an Elasticsearch, Logstash, and Kibana (ELK) stack.

There are multiple ways of hosting an Elasticsearch, Fluentd, and Kibana (EFK) cluster, one of which is the Red Hat OpenShift Logging library. The following instructions reference this library, however, the same configuration also works with other hosted EFK stacks.

For more information about working with EFK integrations, see the following sections:

- About this task
- Prerequisites
- Creating EFK integrations
- Enabling EFK integrations
- Editing EFK integrations
- Deleting EFK integrations
- Troubleshooting

About this task

Before creating the integration, you should be aware of the following information.

- **Load**: To prevent this integration placing an inordinate load on your data source and potentially impacting your logging operations, this integration only connects to one API with a default data frequency of 60 seconds. This is controlled by using the **Sampling rate** setting.
- **Access**: Custom data sources are cloud-based REST APIs. Access is configured by using the authentication methods that are specified in the **Authentication type** setting.
- **Data volume**: Data volume depends on the application, and is not a set value. Therefore, it does not appear in the settings.

Prerequisites

As a prerequisite, you need to make sure that you have an Elasticsearch, Fluentd, and Kibana (EFK) set up on a cluster. There are many ways to set up the EFK stack. One option is to use the Red Hat OpenShift Logging library.

Note: The Red Hat OpenShift Logging library is being deprecated in OpenShift Container Platform 4.14.

Configure EFK with Red Hat OpenShift Logging library:

1. Install the Red Hat OpenShift Logging library. For more information, see the Red Hat OpenShift documentation Installing the logging subsystem for Red Hat OpenShift.

   When you are deploying the Red Hat OpenShift Logging (ClusterLogging) instance, use the following YAML definition as the base for your own definition.

   Change the values for the **`storageClassName`**, **`maxAge`**, and **`size`** depending on your own system. For example, if you are installing on Red Hat OpenShift on IBM Cloud (ROKS), use **`ibmc-file-gold-gid`** for the **`storageClassName`**. If you want to keep application logs for more than 15 days, update the **`maxAge`** value.

```
apiVersion: "logging.openshift.io/v1"
kind: "ClusterLogging"
metadata:
  name: "instance"
  namespace: "openshift-logging"
spec:
  managementState: "Managed"
  logStore:
    type: "elasticsearch"
    retentionPolicy:
      application:
        maxAge: 15d
    elasticsearch:
      nodeCount: 3
      storage:
        storageClassName: "rook-cephfs"
        size: 80G
      resources:
        limits:
            memory: "16Gi"
        requests:
            memory: "16Gi"
      proxy:
        resources:
          limits:
            memory: 256Mi
          requests:
            memory: 256Mi
      redundancyPolicy: "SingleRedundancy"
  visualization:
    type: "kibana"
    kibana:
      replicas: 1
  collection:
    logs:
      type: "fluentd"
      fluentd: {}
```

2. Verify that all pods under the **`openshift-logging`** namespace are running by running the following command.

```
oc get pods -n openshift-logging
```

   If your pods are not running, it can take several minutes for all pods to be in the **`Running`** state. For instance, the **`collector`** pods can go through several restarts before they are all running. You can have several pods for ClusterLogging, Elasticsearch, fluentd (**`collector`**), and Kibana similar to the example output:

```
NAME                                            READY   STATUS      RESTARTS   AGE
cluster-logging-operator-84854b544c-tc758       1/1     Running     0          26m
collector-5hndx                                 2/2     Running     0          10m
collector-6sfk9                                 2/2     Running     0          10m
collector-f5w84                                 2/2     Running     0          10m
collector-fgzsr                                 2/2     Running     0          10m
collector-fhsbk                                 2/2     Running     0          10m
collector-fwdhk                                 2/2     Running     0          10m
collector-hj2q9                                 2/2     Running     0          10m
collector-l4v5q                                 2/2     Running     0          10m
elasticsearch-cdm-medm3kgq-1-74fb867496-swgwx   2/2     Running     0          22m
elasticsearch-cdm-medm3kgq-2-6cb7495ff5-h5bgd   2/2     Running     0          22m
elasticsearch-cdm-medm3kgq-3-5fb8f9f4-bgqgp     2/2     Running     0          22m
elasticsearch-im-app-27288900-b8j28             0/1     Completed   0          2m3s
elasticsearch-im-audit-27288900-btw2x           0/1     Completed   0          2m3s
elasticsearch-im-infra-27288900-ndjcb           0/1     Completed   0          2m3s
kibana-5586499d9b-45x7c                         2/2     Running     0          22m
```

3. **Optional:** If you intend to limit the scope to a particular namespace in your cluster, you can complete the following steps:

    1. Update the ClusterLogging instance `managementState` field from `Managed` to `Unmanaged`. This change can give you more control of the components that are managed by the Red Hat OpenShift Logging Operator. To change the setting, run the following command to edit the instance:

        ```
        oc edit clusterlogging instance -n openshift-logging
        ```

    2. Update the `path` variable in the `collector` configmap under the container logs section.

        You can use the following command to update the configmap.

        ```
        oc edit configmap collector -n openshift-logging
        ```

        As an alternative, you can also use the Red Hat OpenShift Console. To use the console, go to **Workloads** > **ConfigMaps**. Then, from the **Projects** drop-down, select *openshift-logging*. Select the `collector` configmap and edit the YAML. By default, this variable has the following value in the `collector` configmap:

        ```
        path "/var/log/pods/*/*/*.log"
        ```

        Change the value to reference your preferred namespace, for example:

        ```
        path "/var/log/pods/qotd_qotd-*/*/*.log"
        ```

    3. If you updated the collector `ConfigMapRestart` then restart all collector pods (daemonset):

        ```
        oc get pods -n openshift-logging --no-headers=true | awk '/collector/{print $1}' | xargs  oc delete -n
        openshift-logging pod
        ```

4. Expose the log store service as a route. For more information, see the Red Hat OpenShift documentation Exposing the log store service as a route.

    When you are completing this procedure, obtain the token for the `cluster-logging-operator` service account instead of your own Red Hat OpenShift Container Platform token. You must be logged in to the cluster where you installed the `ClusterLogging` instance.

    ```
    token=$(oc sa get-token cluster-logging-operator -n openshift-logging)
    echo $token
    ```

5. When the token variable is set, run the following commands on your workstation to validate that you can connect to Elasticsearch:

    ```
    routeES=`oc get route elasticsearch -o jsonpath={.spec.host} -n openshift-logging`
    curl -tlsv1.2 --insecure -H "Authorization: Bearer ${token}" "https://${routeES}"
    curl -tlsv1.2 --insecure -H "Authorization: Bearer ${token}" "https://${routeES}/_search?scroll=1m"
    ```

    If needed, you can run the following command to get the Elasticsearch version:

    ```
    curl --insecure -H "Authorization: Bearer ${token}" https://${routeES}/
    ```

6. Index the Elasticsearch documents. This indexing is done automatically, but the process can take a few minutes in a new or updated cluster. Wait a few minutes for the changes to display in the Kibana UI.

    When all configuration steps take effect, you can see entries in the Kibana UI for only the application that you intend to collect logs from.

Creating EFK integrations

With EFK set up, you can now create the integration in IBM Cloud Pak for AIOps.

For this integration you need to select the tile for creating an Elasticsearch, Logstash, and Kibana (ELK) integration, but change some settings to connect to EFK instead of ELK.

To create the integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **ELK** tile.

    Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.

5. On the side-panel, review the instructions and when ready to continue, click **Connect**.
6. On the *Add integration* page, define the general integration details:
    - **Name**: The display name of your integration.
    - **Description**: An optional description for the integration.
    - **ELK service URL**: ELK service URL: The Elasticsearch host and public API port. The URL must have the target index that IBM Cloud Pak for AIOps uses to search for the data from your applications. If you want to use all data, specify ***** as your index. For example, your ELK service URL can be **`https://myURL.com:8080/*`**.

      If you are using the Red Hat OpenShift Logging library, then run the following command to find the hostname for the URL:

      ```
      oc get routes -n openshift-logging | grep elastic
      ```

      Example output:

      ```
      elasticsearch    elasticsearch-openshift-logging.apps.demo-apps.cp.mysite.com    elasticsearch    <all>
      reencrypt    None
      ```

      When you have your Elastic hostname, you can build your URL. For example, **`https://elasticsearch-openshift-logging.apps.demo-apps.cp.mysite.com/app*`**. Ensure that you also replace **`/app*`** in the URL with the value for your EFK pattern.
    - **Kibana URL**: Enter a URL for the service instance.

      If you are using the Red Hat OpenShift Logging library, then run the following command to find the hostname for the URL:

      ```
      oc get routes -n openshift-logging | grep kibana
      ```
    - **Authentication type**: Set this value to *Token* to indicate that the Elasticsearch instance is authenticated with a temporary token.

      If you are using the Red Hat OpenShift Logging library, then run the following command to obtain the token for the **`cluster-logging-operator`** service account:

      ```
      token=$(oc sa get-token elasticsearch -n openshift-logging)
      echo $token
      ```
    - **Certificate (optional)**: Certificate used to verify the SSL/TLS connection to the REST service.
    - **Filters (optional)**: A custom Boolean Query to filter the Elasticsearch request for your specific application, terms, keywords, or other filters.
    - **Time zone (optional)**: The time zone in which your data is situated. The default time is converted from the system time relative to UTC time. The default value is UTC.
    - **Kibana port:* The port of the Kibana instance that is on the same host as the Elasticsearch instance. Use **`443`** for this field.
    - **Base parallelism**: Select a value to specify the number of Flink jobs that can run in parallel. These jobs run to process and normalize the collected data. The default value is 1. However, it is recommended to use a higher value than 1 so that you can process data in parallel. This value cannot exceed the total available free Flink slots. In a small environment, the available flinks slots are 16, while in a large environment, the maximum available slots are 32. If you are collecting historical data with this integration, you can set this value to be equal to the **source** parallelism.
    - **Sampling rate**: The rate at which data is pulled from live source (in seconds). The default value is **`60`**.
    - **JSON processing option**: Select a JSON processing option.
        - **None**: The default option. The JSON is not processed or modified.
        - **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
        - **Filter**: This option extracts the JSON object and replaces it with an empty string.
        - For more information about the options, see Managing embedded JSON.

    Note: To improve data throughput, you can increase the base parallelism value incrementally. For more information about maximum base parallelism for starter and production deployments, see Improving data streaming performance for log anomaly detection.

    Note: If you use the Filter option, do not use a timestamp in the filter query. This setting can cause a parsing error in the backend.

    ```
        "range": {
          "@timestamp": {
            "gte": "now-2m",
            "lt" : "now"
          }
    ```

    Other than that limitation, filter can use any clauses so long as the fields and the values specified in the filter are relevant to the target endpoint data set.
7. You can test your integration by clicking **Test connection**.
8. Click **Next**.
9. Enter *Field Mapping* information (Optional):

    You can improve search performance by mapping the fields from your implementation fields to IBM Cloud Pak for AIOps's standard fields.

    Use the following mapping instead of the default mapping that is provided for an ELK integration:

    ```
    {
      "codec": "elk",
      "message_field": "message",
      "log_entity_types": "kubernetes.container_image_id, kubernetes.host, kubernetes.pod_name,
    ```

```
kubernetes.namespace_name",
  "instance_id_field": "kubernetes.container_name",
  "rolling_time": 10,
  "timestamp_field": "@timestamp"
}
```

10. Click **Next**.
11. Enter AI training and log data (Optional):

    Select how you want to manage collecting data for use in AI training and anomaly detection. Click the **Data collection** toggle to turn on data collection, then select how you want to collect data:

    - **Live data for continuous AI training and anomaly detection**: A continuous collection of data from your integration is used to both train AI models and analyze your data for anomalous behavior.

      Note: After an initial installation, there is no data at all in the system. If you select this option, then the three different log anomaly detection algorithms behave in the following ways:

      - Natural language log anomaly detection does not initially detect anomalies as no model has been trained. You can retrieve historical data (select **Historical data for initial AI training**) to speed up the retrieval of data to train on, or you can leave the **Live data for continuous AI training and anomaly detection** setting on. In the latter case, the system gathers training data live and after a few days there is enough data to train a model. When this model is deployed, then it detects anomalies as normal.
      - Statistical baseline log anomaly detection does not detect anomalies for the first 30 minutes of data collection. This is because it does not have a baseline yet. After 30 minutes of live data collection the baseline is automatically created. After that it detects anomalies on an ongoing basis, while continuing to gather data and improve its model every 30 minutes.
      - Log Anomaly Golden Signals does not initially detect anomalies as no model has been trained. The system gathers training data live, and after a few days, there is enough data to train a model. When this model is deployed, it can detect anomalies that deviate from the normal.

    - **Live data for initial AI training**: A single set of training data used to define your AI model. Data collection takes place over a specified time period that starts when you create your integration.

      Note: Selecting this option causes the system to continue to collect data while the option is enabled; however, the data is collected for training only, and not for log anomaly detection. For more information about AI model training, including minimum and ideal data quantities, see Configuring AI training.

    - **Historical data for initial AI training**: A single set of training data used to define your AI model. You need to give Start and End dates, and specify the parallelism of your source data. Historical data is harvested from existing logs in your integration over a specified time period in the past.

      - **Start date**: Select a start date from the calendar and enter the time in hh:mm (hours and minutes) format.

        Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.

      - **Time zone**: Select your time zone from the dropdown list.
      - **End date and time**: Click **Add end date** and select an end date from the calendar and enter the time in hh:mm format.

        Note: If you do not specify the end date, then live data collection follows the historical data collection. If you do not want to set an end date, click **Remove end date**.

      - **Source parallelism (1-50)**: Select a value to specify the number of requests that can run in parallel to collect data from the source. Generally, you can set the value to equal the number of days of datat that you want to collect. When you are setting this value, consider the number of requests that are allowed by the source in a minute. For example, if only 1-2 requests are allowed, set the value to be low.

    Important: Keep in mind the following considerations when you select your data collection type:

    - Anomaly detection for your integration occurs if you select *Live data for continuous AI training and anomaly detection*.
    - Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.

12. Click **Done**.

You created the integration in your instance. After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps.

Enabling and disabling EFK integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **ELK** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section. Set **Data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting an integration, see Deleting EFK integrations.

Editing EFK integrations

After you create your integration, your can edit the integration. For example, if you specified *Historical data for initial AI training* but now want your integration to pull in live data for continuous monitoring, you can edit it. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **ELK** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the ELK integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling EFK integrations. For more information about deleting an integration, see Deleting EfK integrations.

Deleting EFK integrations

If you no longer need your EFK integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before you delete your integration. For more information about disabling data collection, see Enabling and disabling EFK integrations.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **ELK** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the ELK integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating and managing Falcon LogScale integrations

A Falcon LogScale (previously named Humio) integration provides log data, which is used to establish a baseline of normal behavior and then identify anomalies. These anomalies can be correlated with other alerts and events, and published to your ChatOps interface, to help you determine the cause and resolution of a problem.

For more information about working with Falcon LogScale integrations, see the following sections:

- Creating Falcon LogScale integrations
- Enabling Falcon LogScale integrations
- Editing Falcon LogScale integrations
- Deleting Falcon LogScale integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating Falcon LogScale integrations

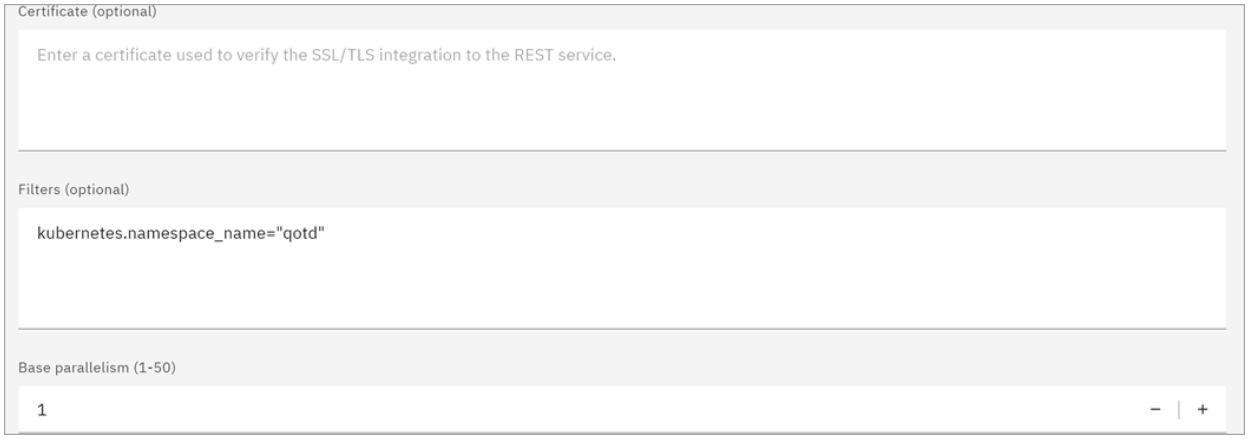
About this task

Before creating the integration, you should be aware of the following information.

- **Load**: To prevent this integration placing an inordinate load on your data source and potentially impacting your logging operations, this integration only connects to one API with a default data frequency of 60 seconds. This is controlled by using the **Sampling rate** setting in the Procedure section.
- **Access**: Custom data sources are cloud-based REST APIs. Access is configured by using the authentication methods that are specified in the **Authentication type** setting in the Procedure section.
- **Data volume**: Data volume depends on the application, and is not a set value. Therefore, it does not appear in the settings.

Procedure

To create a Falcon Logscale integration from a specific source, step through the following sections:



- Adding a Falcon Logscale integration
- Specifying integration parameters

- Specifying field mapping
- Specifying how log data is collected for AI training

Adding a Falcon Logscale integration

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Falcon LogScale** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **Falcon LogScale service URL**: The fully qualified Falcon LogScale query API URL for your Falcon LogScale instance, for example: **`http://<Falcon LogScale_HOSTNAME>/api/v1/repositories/<REPO_NAME>/query`**
   - **API Token**: The integration token for your Falcon LogScale instance, which is available from the account settings page in Falcon LogScale.
   - **Certificate**: An optional certificate used to verify the SSL/TLS connection to the REST service.
   - **Filters**: Optional filters that define subsets of data that is pulled from Falcon LogScale.
   - **Base parallelism**: Select a value to specify the number of Flink jobs that can run in parallel. These jobs run to process and normalize the collected data. The default value is 1. However, it is recommended to use a higher value than 1 so that you can process data in parallel. This value cannot exceed the total available free Flink slots. In a small environment, the available flinks slots are 16, while in a large environment, the maximum available slots are 32. If you are collecting historical data with this integration, you can set this value to be equal to the **source** parallelism.

     caption=
   - **Sampling rate**: The rate at which data is pulled from live source (in seconds). The default value is **`60`**.
   - **JSON processing option**: Select a JSON processing option.
     - **None**: The default option. The JSON is not processed or modified.
     - **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
     - **Filter**: This option extracts the JSON object and replaces it with an empty string.
     - For more information about the options, see Managing embedded JSON.

   Note: To improve data throughput, you can increase the base parallelism value incrementally. For more information about maximum base parallelism for starter and production deployment sizes, see Improving data streaming performance for log anomaly detection.
7. Test your integration by clicking **Test connection**.

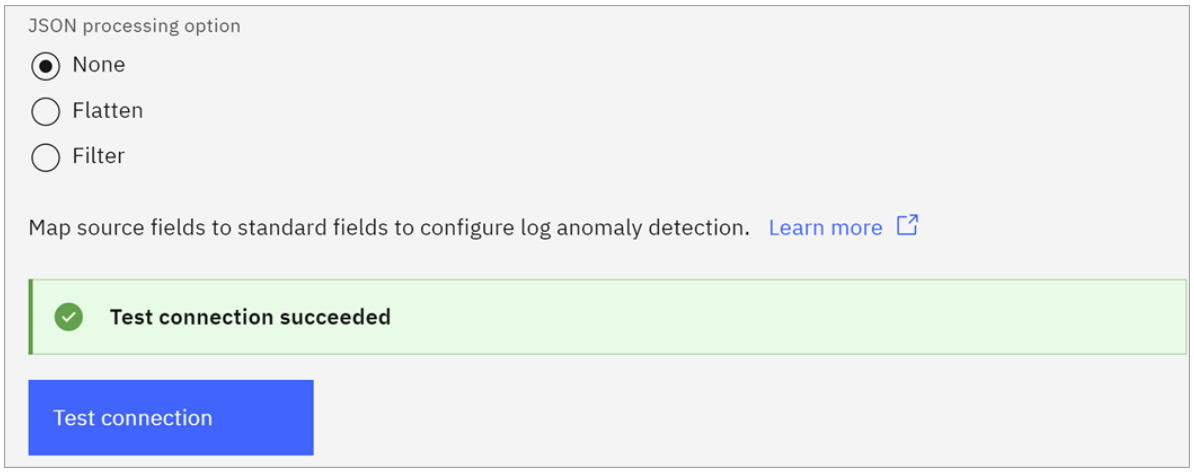


Figure. Test connection

8. Click **Next** to move to the next page.

Specifying field mapping

1. Enter **Field Mapping** information (Optional):

   The default mapping setting that is provided by UI can improve the search performance by mapping the fields from your implementation fields to IBM Cloud Pak for AIOps's standard fields. For more information about how field mappings are defined, see Mapping data from incoming sources. For more information about the use of mappings to clean your data for use in IBM Cloud Pak for AIOps, see Cleaning mapped data that use regular expressions. Consider the supported data schema when you create your field mapping:

   ```
   {
     "codec": "humio",
     "message_field": "@rawstring",
     "log_entity_types": "kubernetes.container_name",
     "instance_id_field": "kubernetes.container_name",
     "rolling_time": 10,
     "timestamp_field": "@timestamp",
     "resource_id": "kubernetes.pod_name"
   }
   ```

   But processing of logs with this format into log anomaly alerts can lead to false alarms in the Alert Viewer.

2. To resolve the false alarms issue in step 1, use regular expression to exclude parts of the log lines at the end of fields mapping (Optional):

   Logs ingested by Falcon LogScale usually have the following format:

   - `_timestamp_ + stdout F + _real message_`
   - `_timestamp_ + stderr F + _real message_`

   You can define the field mapping as follows:

   ```
   {
   "codec": "humio",
   "message_field": "@rawstring",
   "log_entity_types": "kubernetes.container_name",
   "instance_id_field": "kubernetes.container_name",
   "rolling_time": 10,
   "timestamp_field": "@timestamp",
      "custom_regex": [
      ".+?(stdout F )",
      ".+?(stderr F )"
      ]
   }
   ```

3. Click **Next** to move to the next page.

Specifying how log data is collected for AI training

1. Enter *AI training and log data* (Optional):

   Select how you want to manage collecting data for use in AI training and anomaly detection. Set the **Data collection** toggle to 'on', then select how you want to collect data:

   - **Live data for continuous AI training and anomaly detection**: A continuous collection of data from your integration is used to both train AI models and analyze your data for anomalous behavior.

     Note: After an initial installation, there is no data at all in the system. If you select this option, then the two different log anomaly detection algorithms behave in the following ways:

     - Natural language log anomaly detection does not initially detect anomalies as no model has been trained. You can retrieve historical data (select **Historical data for initial AI training**) to speed up the retrieval of data to train on, or you can leave the **Live data for continuous AI**

training and anomaly detection setting on. In the latter case, the system gathers training data live and after a few days there is enough data to train a model. When this model is deployed, then it detects anomalies as normal.

- Statistical baseline log anomaly detection does not detect anomalies for the first 30 minutes of data collection. This is because it does not have a baseline yet. After 30 minutes of live data collection the baseline is automatically created. After that it detects anomalies on an ongoing basis, while continuing to gather data and improve its model every 30 minutes.

- **Live data for initial AI training**: A single set of training data used to define your AI model. Data collection takes place over a specified time period that starts when you create your integration.

  Note: Selecting this option causes the system to continue to collect data while the option is enabled; however, the data is collected for training only, and not for log anomaly detection. For more information about AI model training, including minimum and ideal data quantities, see Configuring AI training.

- **Historical data for initial AI training**: A single set of training data used to define your AI model. You need to give Start and End dates, and specify the parallelism of your source data. Historical data is harvested from existing logs in your integration over a specified time period in the past.

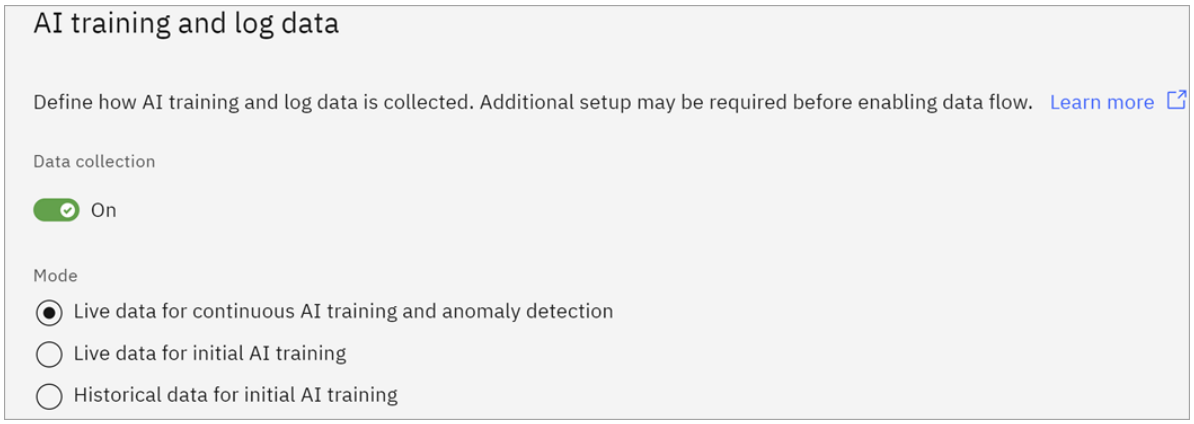

Figure. AI training

- **Start date**: Select a start date from the calendar.

  Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.

- **End date**: Select an end date from the calendar.

  Note: If you do not specify the end date, then live data collection follows the historical data collection.

- **Source parallelism (1-50)**: Select a value to specify the number of requests that can run in parallel to collect data from the source. Generally, you can set the value to equal the number of days of datat that you want to collect. When you are setting this value, consider the number of requests that are allowed by the source in a minute. For example, if only 1-2 requests are allowed, set the value to be low.

  Note: To avoid issues with task manager memory, run no more than one *Historical data for initial AI training* run at a time.

Important: Keep in mind the following considerations when you select your data collection type:

- Anomaly detection for your integration occurs if you select *Live data for continuous AI training and anomaly detection*.
- Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.

2. Click **Next**.
3. On the *Resource requirements* page, you can review the slot usage for your log integrations to see if there are enough slots to fully support the integration for multizone high availability.

   If you set the **Data collection** toggle to **On**, you will see the resource management overview.

   - If your current usage and other usage are less than the provisioned slots, but the HA slots exceed the provisioned slots, you will be able to create the integration, but will see a warning that you do not have enough slots. The integration will not have multizone high availability.
   - If your projected usage exceeds the provisioned slots, you will not be able to create the integration because you do not have enough slots on your system for log data integrations.
   - If your total slots, including HA slots, are within the provisioned slots, the integration will have multizone high availability.

     Note: HA operation assumes high availability for three zones.

   If you set the **Data collection** toggle to **Off**, you will see a message stating that you need to enable logs data collection to see the resource management overview. When data collection is off, no slots are used by that integration.

4. Click **Done**.

You have created a Falcon LogScale integration in your instance. After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling Falcon LogScale integrations.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Enabling and disabling Falcon LogScale integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Falcon LogScale** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section. Set **Data integration** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You have enabled or disabled your integration. For more information about deleting a integration, see Deleting Falcon LogScale integrations.

Editing Falcon LogScale integrations

After you create your integration, your can edit the integration. For example, if you specified *Historical data for initial AI training* but now want your integration to pull in live data for continuous monitoring, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Falcon LogScale** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Falcon LogScale integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Falcon LogScale integrations. For more information about deleting a integration, see Deleting Falcon LogScale integrations.

Once edited, slot usage of log data integrations can be reviewed.

```
![Falcon Logscale integration](../images/int_falconlogscale_editusage.png){: caption="Figure.  Resource requirements" caption-side="bottom"}
```

Deleting Falcon LogScale integrations

If you no longer need your Falcon LogScale integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before deleting your integration. For more information about disabling data collection, see Enabling and disabling Falcon LogScale integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Falcon LogScale** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Falcon LogScale integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating Generic Webhook integrations

If you want to connect to a data source and a dedicated integration is not available for that source in the IBM Cloud Pak for AIOps Integrations UI, you can use the generic webhook integration. This integration provides an endpoint for applications to send JSON formatted events to IBM Cloud Pak for AIOps through HTTP POST requests.

In the requests you can also include JSONata that maps incoming JSON payloads to IBM Cloud Pak for AIOps events.

For more information about working with a generic webhook integrations, see the following sections:

- Before you begin
- Creating a Generic Webhook integration
- Editing a Generic Webhook integration
- Deleting a Generic Webhook integration

Before you begin

To configure a generic webhook integration, you need the following information for the application that you are connecting to IBM Cloud Pak for AIOps:

- A name and description for the webhook integration.
- If you need to secure the webhook, the appropriate user name and password.
- The JSONata that maps the incoming JSON payload to IBM Cloud Pak for AIOps events.

Creating a Generic Webhook integration

To create a Generic Webhook integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Generic Webhook** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section (Events).
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration. You cannot use spaces or special characters in the display name. Use only alphanumeric characters.
   - **Description**: An optional description for the integration.
   - **Authentication type**: Select the **Username/Password** or **None** option.
   - **Username**: Enter the appropriate username to authenticate the connection.
   - **Password**: Enter the appropriate password to authenticate the connection.
   - **Webhook route**: The predefined full URL (location) of the webhook. This field is not editable.
   - **Maximum event rate**: The maximum number of events (per second) that are allowed by the Generic Webhook integration. You must specify a value between 10 and 1000 events per second. The default is 100.
     Note: The actual rate that events are collected depends on network performance.
7. Click **Next**.
8. Configure the event mapping.

   Use JSONATA to map the incoming JSON payload to the IBM Cloud Pak for AIOps event data schema. You can start from scratch or load an example mapping. The mapping configuration will be tested to ensure that it is in a valid JSONata format.

   Click **Load sample mapping** to show a selection of available samples and select an appropriate use case to load. For example, you can select **SevOne** or **Turbonomics**. Finish the mapping by clicking the **Load sample mapping** button.

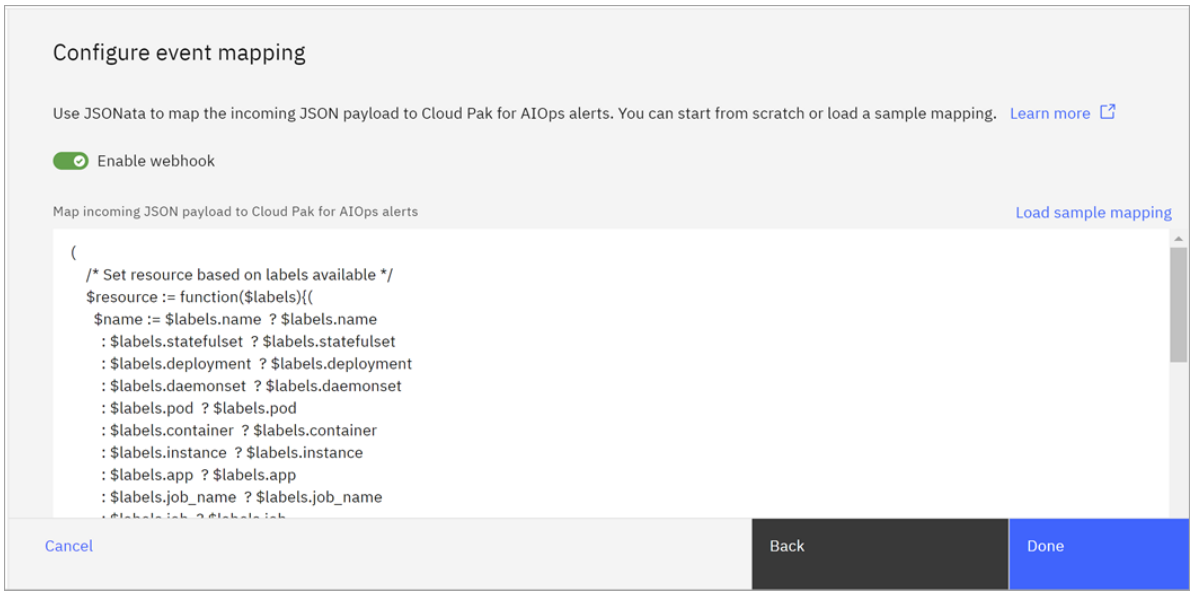

Figure. Configure event mapping

The following mapping is an example mapping for an integration with IBM SevOne Network Management System (NMS)

```
(
    {
        "severity": alertState="Alert"?6:alertState="Emergency"?6:alertState="Critical"?6:alertState="Error"?
5:alertState="Warning"?3:alertState="Notice"?2:alertState="Info"?2:alertState="Debug"?2:1,
        "summary": description,
        "resource": {
            "name": deviceName
        },
        "type": {
            "classification": policyName,
            "eventType":  alertState = "Cleared" ? "resolution" : "problem"
        },
        "sender": {
            "name": "IBM SevOne Network Management System",
            "type": "Webhook Integration"
        },
        "expirySeconds": alertId="-1"?300
    }
)
```

Note: The JSONata expression must contain the `summary`, `resource` and `type` fields. If the fields are missing, the event is invalid and might be rejected. Values mapped to the `classification` field in the data model are especially significant. Inappropriate values assigned to this field at the time of mapping has a negative impact on several downstream activities, such as Golden Signal classification, incident creation, and recommended policies. Classification should contain information summarizing the event type, for example, CPU Utilization, Node Down, or the actual metric name itself.

Review the following topics for more example mappings to help you configure your own mappings:

- Example: IBM SevOne Network Management System (NMS) generic webhook event mappings
- Example: Prometheus AlertManager (Red Hat OpenShift) generic webhook event mappings

9. Enable the webhook. Click the toggle to change the setting **Enable webhook** or **Disable webhook**. When disabled, the webhook integration discards incoming HTTP requests.
10. Click **Done**.
11. Within the application that you are connecting to IBM Cloud Pak for AIOps, complete any required configurations to support the integration.

    Important: You might need to configure a signed trusted certificate for IBM Cloud Pak for AIOps that the external system that you are connecting to trusts. When an external system is sending a payload through this webhook integration, the payload goes through a TLS handshake. If IBM Cloud Pak for AIOps is using the default configuration, IBM Cloud Pak for AIOps uses self-signed certificates that an external system will not accept if the system does not trust self-signed certificates. To configure a signed trusted certificate, If you are connecting to a SaaS system, you might need to use an internationally recognised certificate authority certificate as you might need be able to update the SaaS trusted certificate authority list. Otherwise, you can use your own certificate authority and add the certificate to the external system.

    For example, to connect to IBM SevOne Network Management System (NMS) you need to complete the following tasks:

    - Copy the Webhook URL from IBM Cloud Pak for AIOps.
    - Importing a CA signer certificate into IBM SevOne Network Management System (NMS).
    - Add the webhook destination within IBM SevOne Network Management System (NMS).

      In the IBM SevOne Network Management System (NMS) UI go to **Events** > **Configuration** > **Policy Browser** > **Configure webhook destination** > **Add webhook destination**.
    - Add the webhook into existing policies to send event data to IBM Cloud Pak for AIOps.

12. Test your integration with your connected application to verify that events are sent to IBM Cloud Pak for AIOps, and display as alerts in the Alert Viewer of the IBM Cloud Pak for AIOps UI.

Enabling or disabling a Generic Webhook integration

After you create your webhook integration, you can enable or disable the webhook by completing the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Generic Webhook** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *Generic Webhook* page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Enable or disable the webhook by clicking the toggle to change the setting to **Enable webhook** or **Disable webhook**. When disabled, the webhook integration discards incoming HTTP requests.
6. Click **Save** when you are done.

Your webhook is now enabled or disabled.

Editing a Generic Webhook integration

After you create your integration, you can edit the integration. For example, if you want to add or change the listed GUI or backend URLs for the IBM Tivoli Netcool/Impact endpoint, or to update the User ID or password. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Generic Webhook** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *Generic Webhook* page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited.

Deleting a Generic Webhook integration

If you no longer need your integration and want to delete it entirely, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Generic Webhook** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the *Generic Webhook* integrations page, click the *Delete* icon for the integration that you want to delete.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Integrating with IBM SevOne Network Performance Management

You can use a generic webhook integration to integrate IBM Cloud Pak for AIOps with IBM SevOne Network Performance Management.

For details see Creating Generic Webhook integrations.

Configuring IBM SevOne Network Management System (NMS) to forward events to the webhook integration for SevOne

IBM SevOne NMS must be configured with a new webhook configuration to send alerts to the webhook integration for SevOne NMS.

Note: Instructions to configure the webhook with SevOne NMS can differ depending on your SevOne NMS version. For more information about using the SevOne Webhook Definition Manager and configuring alerts in SevOne NMS, see NMS 6.6 Guides and the SevOne NMS User Guide.

Note IBM SevOne requires the webhook destination to use a TLS certificate signed by a trusted Certificate Authority (CA).

1. Log in to the IBM SevOne console.

2. On the top menu, go to **Events > Configuration > Webhook Definition Manager**.
3. On the Policy Browser page, click **Configure Webhook Destination** on the Policies panel.
4. Complete the following steps from the Add Webhook Destination panel:
    1. Set a Webhook Destination Name, for example: IBM Cloud Pak for AIOps Webhook
    2. Set a Description, for example: Webhook integration for SevOne NMS
    3. You can obtain the webhook URL from the Integrations UI page.
    4. Select the **Allow insecure webhook connection** option if the webhook integration uses a self-signed certificate.
    5. Expand the Headers section and select **Use Basic Auth**. Then, set the **Username** and **Password** fields with the credentials set in **Step 6)** of Creating a Generic Webhook integration.
    6. In the **Request Options**, select **POST** as the Request Method, **application/json** as the Content Type, and use the following sample body:

```
  {
      "routes": ["IBM CloudPak for AIOps"],
      "host": "$deviceName",
      "description": "$alertMessage",
      "alertMessage": "$alertMessage",
      "check": "$policyName - $objectName",
      "cluster": "$clusterName",
      "alertId": "$alertId",
      "alertType": "$alertType",
      "alertState": "$alertState",
      "occurrences": "$occurrences",
      "assignedTo": "$assignedTo",
      "deviceId": "$deviceId",
      "deviceIp": "$deviceIp",
      "deviceName": "$deviceName",
      "deviceAltName": "$deviceAltName",
      "groupName": "$groupName",
      "objectId": "$objectId",
      "objectName": "$objectName",
      "objectAltName": "$objectAltName",
      "objectDescription": "$objectDescription",
      "pluginName": "$pluginName",
      "pluginDescription": "$pluginDescription",
      "policyId": "$policyId",
      "policyName": "$policyName",
      "thresholdId": "$thresholdId",
      "thresholdName": "$thresholdName",
      "linkURL" : "<DI_URL.com/redirect/v1/reports?reportName=Indicator%20Summary&$DIDataResources|View in Data
Insight>",
      "triggeringConditions": $triggeringConditions,
      "closureMessage": "$closureMessage"
  }
```

    7. Click **Test Definition** to send a test HTTP event to the webhook integration. Test both the triggering condition and clear condition webhooks to ensure that the recieved response code is `200` or `204`.
    - A `204` status code indicates that no payload is included in the HTTP response, but the integration is successful.
    - If a response code of `400 Bad request` is received, check the JSON template that is configured. Ensure that the JSON does not contain any syntax errors.
    8. Click **Save**.
5. Configure or create policies to send events to the webhook integration by selecting the webhook integration as the webhook destination. For each of the policies in the **Webhooks** section, select the webhook that was created in the previous step. Complete the selection for the **Trigger Conditions** and **Clear Conditions** tabs. By default, SevOne alerts configuration enables **One Webhook per Alert** option which only sends one webhook on the first trigger condition and not subsequent triggers. You can opt to select **Override Webhook per alert** and deselect **One Webhook per Alert** option to trigger webhook on each alert trigger to send alert updates to your webhook.

Integrating with IBM Turbonomic

You can use a generic webhook integration to integrate IBM Cloud Pak for AIOps with IBM Turbonomic.

For details see Creating Generic Webhook integrations.

Configuring IBM Turbonomic to forward events to the webhook integration for Turbonomic

IBM Turbonomic must be configured with a new webhook configuration to send alerts to the webhook integration for Turbonomic.

Creating a workflow

1. Set the following variables:

```
TURBONOMIC_HOSTNAME=<api endpoint hostname>
TURBONOMIC_ADMIN_USER=<turbonomic username>
TURBONOMIC_ADMIN_PASSWORD=<turbonomic password>
AIOPS_WEBHOOK_URL=<webhook integration URL>
BASIC_AUTH_USERNAME=<webhook basic authentication username>
BASIC_AUTH_PASSWORD=<webhook basic authentication password>
```

Note: Update the values set for **AIOPS_WEBHOOK_URL**, **BASIC_AUTH_USERNAME** and **BASIC_AUTH_PASSWORD**. You can obtain these values from the AIOps Webhook integration configuration.

2. Get the JSESSIONID token

```
JSESSIONID=$(curl \
--silent \
--cookie-jar - \
--insecure \
https://${TURBONOMIC_HOSTNAME}/api/v3/login?hateoas=true \
--data "username=${TURBONOMIC_ADMIN_USER}&password=${TURBONOMIC_ADMIN_PASSWORD}" \
| awk '/JSESSIONID/{print $7}')
```

3. Create a workflow

```
curl \
"https://${TURBONOMIC_HOSTNAME}/api/v3/workflows" \
--insecure \
--compressed \
--header 'Accept: application/json' \
--header 'Content-Type: application/json' \
--header "cookie: JSESSIONID=${JSESSIONID}" \
--request POST \
-vv \
--data @- <<EOF
{
"displayName": "Event Webhook integration",
"className": "Workflow,
"description": "Event webhook integration",
"discoveredBy": {
    "readonly": false
},
"type": "WEBHOOK",
"typeSpecificDetails": {
  "url": "${AIOPS_WEBHOOK_URL}",
  "method": "POST",
  "authenticationMethod": "BASIC",
  "username": "${BASIC_AUTH_USERNAME}",
  "password": "${BASIC_AUTH_PASSWORD}",
  "template": "\$converter.toJson(\$action)",
  "trustSelfSignedCertificates": true,
  "headers": [
     {
      "name": "Content-type",
      "value": "application/json"
     }
   ],
  "type": "WebhookApiDTO"
  }
}
EOF
```

4. Get the workflow UID for later use.

```
WORKFLOW_UUID=$(curl \
"https://${TURBONOMIC_HOSTNAME}/api/v3/workflows" \
--insecure \
--compressed \
--header 'Accept: application/json' \
--header 'Content-Type: application/json' \
--header "cookie: JSESSIONID=${JSESSIONID}" \
--request GET | jq -c ".[] | select(.typeSpecificDetails .
url | contains(\"${AIOPS_WEBHOOK_URL}\")) | .uuid" | tr -d '"')
```

Create a policy

1. Log in to the Turbonomic console.
2. Navigate to the *Settings* page and then choose **Policies**.
3. Click **New Automation Policy** and then select the policy type, **Virtual Machine** in this case. This sets the type of entity that your policy will affect. Refer to Working with policies for more information.

   Name the policy

   - **Add Scope** The scope determines which entities this policy will affect. Choose one or more groups, or create new groups and add them to the policy scope. These groups match the type of entity you have set for the policy.
   - **Policy Schedule** The *Select Schedule* fly-out lists all the schedules that are currently defined for your instance of Turbonomic. Expand a schedule entry to see further details, or skip it if you don't need the schedule.
   - **Automation and Orchestration** You can define automation and orchestration settings for different action types within the same policy.
     - **Action Type** See a list of actions that are viable for the policy, and then make your selections.
     - **Action Generation and Acceptance**
       - Do not generate actions as Turbonomic doesn't considers your selected actions in its calculations. For example, if you do not want to generate resize actions for VMs in the policy, analysis will still drive toward the desired state, but will do so without considering resizes.

- Generate Actions Turbonomic generates your selected actions to address or prevent problems. Choose from the following *Action Acceptance* modes to indicate how you would like the actions to run:
  - **Recommend** Recommend the action so a user can run it via the given hypervisor or by other means
  - **Manual** Recommend the action, and provide the option to run that action through the Turbonomic user interface
  - **Automatic** Run the action automatically For automated resize or move actions on the same entity, Turbonomic waits five minutes between each action to avoid failures associated with trying to run all actions at once. Any action awaiting execution stays in queue.
- **Before Execution and Action Execution:** By default, generated actions run without the need for orchestration. Turbonomic gives you the ability to set up orchestration to affect the execution of actions.
- **After Execution**: The default is to 'do nothing'. Other options include:
  - **Create Record in Orchestration** Turbonomic registers the action in the Orchestration log, showing that the given action has been run. For example: A final ActionID could be created and with the final ActionState, the Type and Severity would be updated accordingly in IBM Cloud Pak for AIOps. Those actions would also be updated to IBM Cloud Pak for AIOps, and it would handle with the alerts with updated state: closed or cleared or keep open.
  - **Use Action Script** Run an action script that is set up for the POST entrypoint. The action script name must match the entity type and action type.

4. Save the policy.
5. Action events will be sent to the webhook integration when an action is run.

Integrating with Zabbix

You can use the generic webhook integration to integrate Zabbix with IBM Cloud Pak for AIOps.

To do so, use the instructions in the following sections:

- Creating a Generic Webhook integration
- Creating a new webhook media type for CP4WAIOPs
- Assigning the CP4WAIOPs webhook media type into Admin user
- Creating a Zabbix Trigger Action to send notification to CP4WAIOPs

Creating a Generic Webhook integration for Zabbix

To create a Generic Webhook integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Generic Webhook** tile.
5. Click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration. For example `zabbix-demo`
   - **Authentication type**: Select **None**.
7. Click **Next**.
8. Configure the event mapping.

   Use JSONATA to map the incoming JSON payload to the IBM Cloud Pak for AIOps event data schema.

   Copy the following Zabbix JSONATA expression into the text area:

```
(
   {
      "severity": severity="5"?6:severity="4"?5:severity="3"?4:severity="2"?3:severity="1"?2:1, "summary": message,
      "resource": {
         "name": deviceName,
         "hostname": hostname,
         "ipAddress": ipaddress,
         "sourceId": hostid,
         "port": hostport
   },
   "type": {
      "classification": triggerdesc,
      "eventType": recoveryValue = "0" ? "resolution" : "problem"
   },
   "sender": {
```

```
      "name": "Zabbix",
      "sourceId": $exists(actionName) ? $length(actionName) > 0 ? "Trigger action: " & actionName,
      "type": "Webhook Connector"
      }
   }
)
```

9. Click **Done**.
10. You should see the newly created **zabbix-demo** webhook integration. Copy the webhook route. You will need to paste this route into the Zabbix configuration later.

Creating a new webhook media type for CP4WAIOPs

Before creating a new webhook media type for CP4WAIOPs, you must a create a cp4waiops-webhook.yaml file that you will import into your Zabbix server.

To create the YAML file, you can use the example YAML that follows. This example supports both basic authentication and no authentication types as defined in the CP4WAIOPs Generic webhook connection.

If you want to use authentication, set **req_username** and **req_password** for basic authentication.

If you do not want to use authentication, remove the **req_username** and **req_password** variables from the YAML.

Sample CP4WAIOPS Connector Media type YAML

```
zabbix_export:
  version: '6.4'
  media_types:
    - name: 'CP4WAIOPS connector demo'
      type: WEBHOOK
      parameters:
        - name: actionName
          value: '{ACTION.NAME}'
        - name: deviceName
          value: '{HOST.NAME}'
        - name: hostid
          value: '{HOST.ID}'
        - name: hostname
          value: '{HOST.HOST}'
        - name: hostport
          value: '{HOST.PORT}'
        - name: HTTPProxy
        - name: ipaddress
          value: '{HOST.IP}'
        - name: message
          value: '{ALERT.MESSAGE}'
        - name: recoveryValue
          value: '{EVENT.RECOVERY.VALUE}'
        - name: req_password
          value: password
        - name: req_username
          value: admin
        - name: sendTo
          value: '{ALERT.SENDTO}'
        - name: severity
          value: '{EVENT.NSEVERITY}'
        - name: subject
          value: '{ALERT.SUBJECT}'
        - name: triggerdesc
          value: '{TRIGGER.DESCRIPTION}'
        - name: zabbixServer
          value: '{$ZABBIX.URL}'
      script: |
        try {

            var params = JSON.parse(value),
                req = new HttpRequest(),
                response;

            if (typeof params.HTTPProxy === 'string' && params.HTTPProxy.trim() !== '') {
                req.setProxy(params.HTTPProxy);
            }
            var data = {};
            data.message = params.message;
            data.severity = params.severity;
            data.deviceName = params.deviceName;
            data.hostname = params.hostname;
            data.hostid = params.hostid;
            data.hostport = params.hostport;
            data.ipaddress = params.ipaddress;
            data.subject = params.subject;
            data.recoveryValue = params.recoveryValue;
            data.triggerdesc = params.triggerdesc;
            data.actionName = params.actionName;
            data.sendTo = params.sendTo;
            data.zabbixServer = params.zabbixServer;
            data = JSON.stringify(data);

            req.addHeader('Content-Type: application/json');
```

```
            if (params.req_username !== '' && params.req_password !== '') {
               req.addHeader('Authorization: Basic ' + btoa(params.req_username + ':' + params.req_password));
            }

            Zabbix.log(4, '[ CP4WAIOPS webhook ] URL: ' + params.sendTo + ' data: ' + data);
            response = req.post(params.sendTo, data);
            Zabbix.log(4, '[ CP4WAIOPS webhook ] Responded with code: ' + req.getStatus() + '. Response: ' + response);

            if (response !== null) {
                try {
                    response = JSON.parse(response);
                    if (response.Status < 200 || response.Status >= 300) {
                        throw 'Request failed with status code ' + response.Status + ' error: ' + response.ErrorMessage;
                    }
                }
                catch (error) {
                    if (req.getStatus() < 200 || req.getStatus() >= 300) {
                        throw 'Request failed with status code ' + req.getStatus() + ' error: ' + response.ErrorMessage;
                    }
                    else {
                        throw 'Request success, but response parsing failed.';
                    }
                }
            }
            return 'OK';
        }
        catch (error) {
            Zabbix.log(3, '[ CP4WAIOPS webhook ] Sending failed. Error: ' + error);
            throw 'Failed with error: ' + error;
        }
      description: 'webhook media type for Cloud Pak Watson AIOPS - Webhook connector'
      message_templates:

            {EVENT.UPDATE.MESSAGE}

            Current problem status is {EVENT.STATUS}, age is {EVENT.AGE}, acknowledged: {EVENT.ACK.STATUS}.
```

To create a new webhook media type for CP4WAIOPs

1. Log in to your Zabbix server web GUI. Click **Alerts > Media types**.
2. Click **Import** in the top right corner. Click **Choose file** from the pop-out windows, select the cp4waiops-webhook.yaml file you created previously, make sure the **Create new** box is checked, and click **Import**.

Note: If you already had imported the cp4waiops webhook media type and want to update the existing one, check the **Update existing** box.

3. A new media should now be showing up in the media type list. This new media type has not yet been assigned to a trigger action, and so the **Used in action** field will be blank.
4. To test the new webhook media type, click Test in the Action column and fill in the required fields. In the **sendTo** field, paste in the details of the CPWAIOPs webhook connection route from Creating a Generic Webhook integration for Zabbix.
5. Click **Test**.
6. If the test is successful, you should receive the response `OK` and the message: `Media type test successful`. In CP4WAIOPs, you should receive the test POST message from Zabbix.

Assigning the CP4WAIOPs webhook media type into Admin user

After you have created and tested the new media type, you must assign the media type into the Admin user.

1. At the Zabbix web GUI side bar, click **Users > Users** to access the **Users** page. Click **Admin**.

2. Click the **Media** tab.
3. On the **Media** tab, click **Add**.
4. On the Media windows, select the integration that you created in Creating a Generic Webhook integration for Zabbix from the Type filed. Fill in the **Send to** field with the webhook connector route. Ensure the **Enabled** box is checked. Click **Add**.
5. You should see the new entry in media type now. Click **Update** to save it. You have now assigned the CP4WAIOPs media type to the Admin user.

Creating a Zabbix Trigger Action to send notification to CP4WAIOPs

After assigning the media type to the Admin user, you need to create a trigger action in Zabbix.

1. At the Zabbix web GUI side bar, click **Alerts > Actions > Trigger actions**. Click **Create action** in the top right corner. You need to create a trigger action that will send notifications to CP4WAIOPs using the integration that you created in Creating a Generic Webhook integration for Zabbix.
2. Complete the **Name** field, for example enter `Send CP4WAIOPs notification`.
3. Click **Add** under the **Conditions** section. A **New condition** window will pop-out. Define the condition where you want to send notification for this group of resource types. For example, select the **Host** as resource type.
4. Click **Select** from the **Hosts** section.
5. A **Hosts** window will pop-out. Click **Select** in the **Host Group** section. A **Host groups** window will pop-out to show you all available host groups that you can select from.
6. Select the host groups or hosts that you want to send notification to CP4WAIOPs. Click **Select**.
7. Click **Add** to add them into your trigger condition.
8. Now you should have set your trigger condition. Make sure check the **Enabled** box.
9. Click on the **Operations** tab. Click **Add** under the **Operations** section.
10. The **Operation details** window should pop-out. In the **Send to users** section, click **Select** and select **Admin**. In the **Send only** to section, click **Select** and select the integration that you created in Creating a Generic Webhook integration for Zabbix. Click **Add** to add the operation details.
11. Repeat Step 10. for the **Recovery operations** and **Update operations** sections. Click **Add**.
12. You should see an **Action Added** message. You have now created a trigger action with the name `Send CP4WAIOPs notification` that will trigger CP4WAIOPs notifications through the Admin user.

Example: IBM SevOne Network Management System (NMS) generic webhook event mappings

Review the following example mappings for a generic webhook integration between IBM Cloud Pak for AIOps and IBM SevOne Network Management System (NMS). Use these mappings to help you configure your own event mapping for a generic webhook integration.

- Example event (alert) JSON
- Example event mapping JSONata expression
- Example event result JSON
- Example Curl Command

```

Creating IBM Infrastructure Management integrations

You can send event data, inventory data, and metrics data from Infrastructure Management to IBM Cloud Pak for AIOps through an Infrastructure Management integration.

- Before you begin
- Creating Infrastructure Management integrations
- Editing Infrastructure Management integrations
- Deleting Infrastructure Management integrations

Before you begin

Before you configure an Infrastructure Management integration, ensure that the following prerequisites are met:

- You have a working Infrastructure Management cluster. Infrastructure Management must be installed on an Red Hat OpenShift Container Platform cluster. The integration cannot be created for an Infrastructure Management appliance that is running on a virtual machine (VM).
- Event syndication, inventory syndication, and metrics syndication must be enabled within Infrastructure Management as required.

  For information on how to enable event, inventory, and metrics syndication, see *Enabling events, inventory and metrics syndication* within the topic General Configuration.

Note: Infrastructure Management and Cloud Pak for AIOps can be located in the same cluster or in different clusters.

Creating Infrastructure Management integrations

To create an Infrastructure Management integration, complete the following steps:

1. Log in to the IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the **Integrations** page, click **Add integration**.
4. From the list of available integrations, find and click the Infrastructure Management tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Select the **Events**, **Topology**, and **Metrics** from the **Category** list.
5. On the side panel, review the information and when ready to continue, click **Get started**.

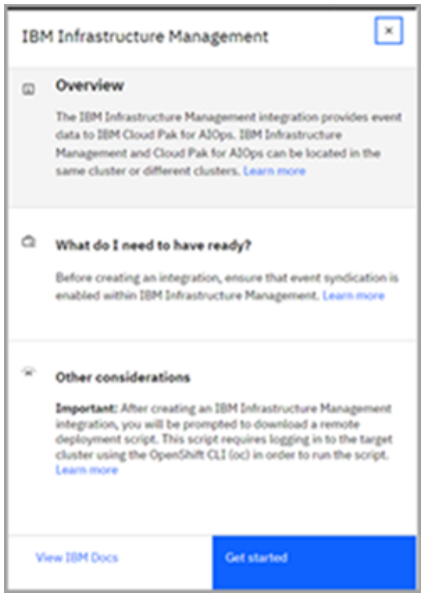

Figure. Add Infrastructure Management integration - get started

6. On the Add integration page, define the general integration details:

   Name: The display name for the integration.

   Description (optional): An optional description for the integration.

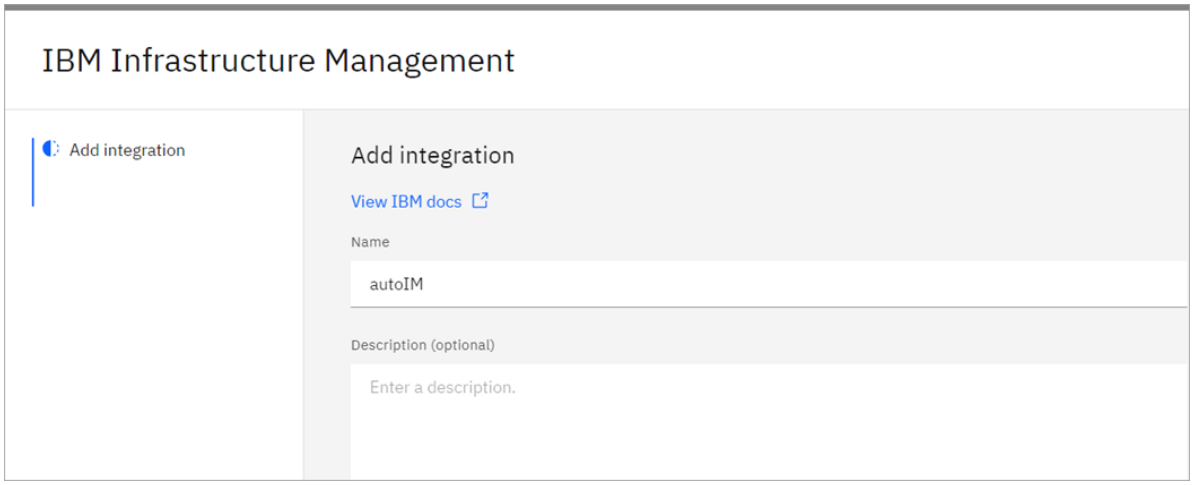

Figure. Add Infrastructure Management integration

7. Click **Done**.

   Important: After creating the integration, you are prompted to copy or download a boostrap command for running a remote deployment script. The script is generated when you create the integration in IBM Cloud Pak for AIOps. This script is required for establish the integration from Infrastructure Management to IBM Cloud Pak for AIOps.

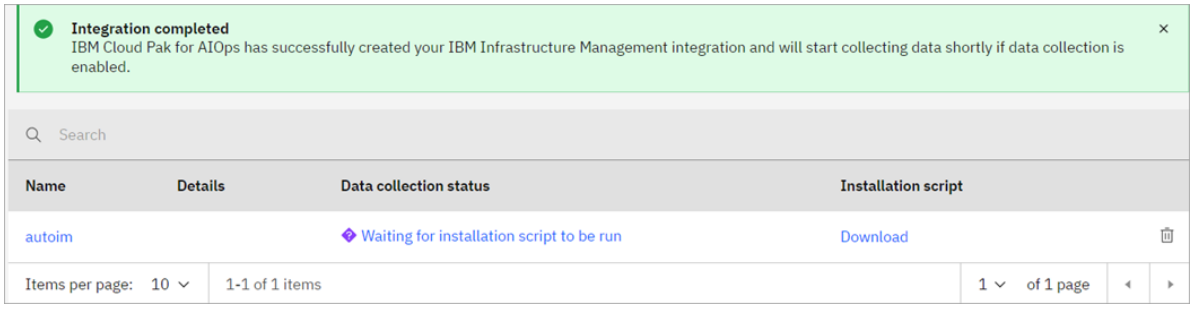

Figure. Add Infrastructure Management integration - completed

8. Copy or download the bootstrap command for the deployment script.

   You can click the **Copy to clipboard** button to copy the command, or click **Download as shell script** to download the command as a `bootstrap.sh` file.

   Note: If you do not obtain the command now, you can copy or download the command later by completing the following steps:

   1. Log in to IBM Cloud Pak for AIOps console.

2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Infrastructure Management** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Infrastructure Management page, click the **Download** link in the **Remote deployment script** column for the integration.
5. Either copy or download the bootstrap command for the deployment script.

9. Run the remote deployment script on your Infrastructure Management cluster.
    1. Get the OpenShift CLI `oc login` command from the cluster where Infrastructure Management is installed.
    2. From a command line, log in to the Infrastructure Management cluster with the `oc login` command.
    3. Switch to the project (namespace) where Infrastructure Management is installed.
    4. Run the deployment script as a `sh` (script file), such as the downloadable `bootstap.sh` file.

Editing Infrastructure Management integrations

After you create a integration, you can edit the integration to update the name or description. Complete the following steps to edit the integration:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Infrastructure Management** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Infrastructure Management page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required.
6. Click **Save** when you are done editing.

Deleting Infrastructure Management integrations

If you no longer need your IBM Infrastructure Management integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete a integration, you need to complete the following steps for IBM Cloud Pak for AIOps. Then, you need to complete steps on your Infrastructure Management to remove the integration deployment. The deployment on the cluster is not removed when you delete the integration in the IBM Cloud Pak for AIOps console for IBM Cloud Pak for AIOps.

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **IBM Infrastructure Management** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the IBM Infrastructure Management integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**. Your integration is deleted.
6. Delete the integration deployment on your Infrastructure Management cluster. To delete the deployment, you must manually run OpenShift CLI (`oc`) commands against the cluster.
    1. From a command line, use the `oc login` command to log in to your Infrastructure Management cluster.
    2. Switch to the project (namespace) where Infrastructure Management is installed.

       ```
       oc project <project>
       ```

       Where `<project>` is the project (namespace) where Infrastructure Management is installed.
    3. Delete the `grpc-bridge-secret` secret.

       ```
       oc delete secret grpc-bridge-secret
       ```
    4. Delete the integration deployment

       ```
       oc delete deploy aiops-connector
       ```

       The deployment is now deleted from your Infrastructure Management cluster.
    5. Delete the `aiops-connector-allow-kafka` network policy:

       ```
       oc delete networkpolicy aiops-connector-allow-kafka
       ```

Creating Instana integrations

You can integrate with Instana to enable connectivity to Instana events, metrics, and topology by using an Instana integration. Instana assets can be combined with IBM Cloud Pak for AIOps AI, such as runbooks, metric anomaly detection, and log anomaly detection to help you gain insights.

If needed, you can create multiple Instana integrations. This deployment model has only one topology processor and multiple Instana integrations. The topology processor treats each integration as a distinct topology provider.

Important: You can use the Instana Collector or the Instana Observer to retrieve topology data from an integration with Instana, **but not both**. See Configuring Instana Observer jobs for information on using the Instana Observer.

The list of technologies is determined dynamically, based on the actual resources available in the Instana instance the integration is pulling metrics data from. Each technology includes a list of all available metrics that can be dynamically retrieved by the Instana integration. The integration also provides a set of recommended metrics to select from.

For more information about working with Instana integrations, see the following sections:

- Before you begin
- Creating Instana integrations
- Enabling Instana integrations
- Editing Instana integrations
- Deleting Instana integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Before you begin

Ensure that you have following information to hand:

- Endpoint
- API Token
- Filters to define subsets of data that is pulled from Instana (optional)

Creating Instana integrations

To create an Instana integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Instana** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **Endpoint**: Enter an endpoint for the integration. For example `https://myinstance.mydomain.com`.
   - **API token**: Enter an API token for the integration. The API Token can be fetched from the Instana web UI.

Figure. Add Instana integration

   - **Deployment options**: Select between the *local* or *remote* radio buttons. If you select remote, after adding the integration, you will be provided with a bootstrap command to finish the deployment.

- **Test connection**: click to see is the connection can be established.

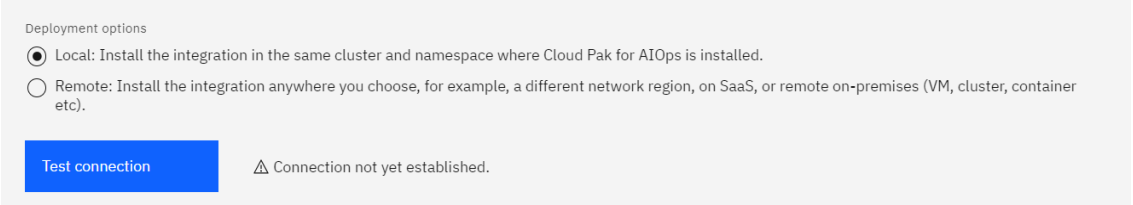

Figure. Test connection

Note: To use the Instana API for the collection of Instana data (metrics, events, and topologies), an API token is required. These API tokens can be created on the Instana user interface. Click the **Settings** icon, then **Team Settings > API Tokens**, and lastly click **Add API Token** to create a new API token.

The default configuration for a new API token is enough for this Instana integration.

7. Click **Next**.
8. If you would you like to optionally use an HTTP proxy configuration with the Instana integration, enter the following *Configure proxy* information:
   - **Proxy URL**: Enter the URL or domain name of the Proxy Server including the protocol. Do not include the port in the Proxy URL field.
   - **Proxy Port**: Enter the port as a number in the Proxy Port field.
   - **Proxy Username**: If the HTTP proxy server requires authentication, enter the proxy username. If not, you can leave this field blank to use the proxy without authentication.
   - **Proxy Password**: If the HTTP proxy server requires authentication, enter the proxy password. If not, you can leave this field blank to use the proxy without authentication.

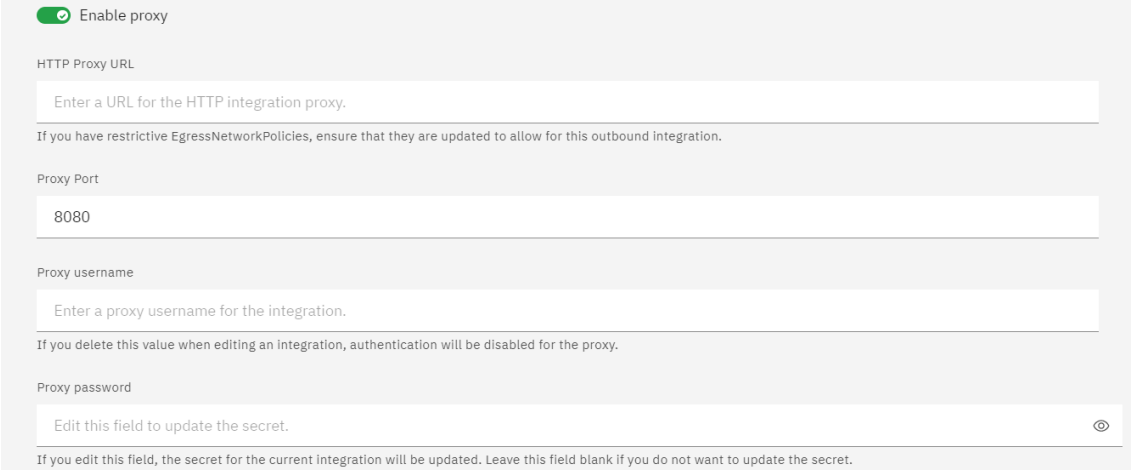

Figure. Configure proxy

Note: An HTTPS proxy server and certificate authentication are not supported for the proxy configuration. Only basic authentication (username and password) or no authentication with an HTTP proxy server are supported.

9. Click **Next**.
10. Enter the following *Collect topology data* information:
    - **Enable data collection**: Enable the toggle button.
    - **Time window (seconds)**: Reference the windowSize within the Instana API.
    - **Integration interval (seconds)**: Specify a time period for how frequently to run the job.
    - **Application name allowlist pattern**: Filter app perspective collection based on the name of the application.
    - **Import Instana application perspectives as Cloud Pak for AIOps applications**: Enable the toggle button (if required).

      Note: When this toggle button is enabled, an IBM Cloud Pak for AIOps application for each application perspective in Instana is automatically created. If it is not turned on, then you create resource groups for only the services that are part of that application in Instana. So, you have the opportunity to define your own IBM Cloud Pak for AIOps applications, by adding your own group to the application. It's important to note that if the application is created automatically by enabling the toggle button, the application is not controlled by the user. It is the product itself that controls the application. Only if you create the application yourself can you control the lifecycle of the application, and thus remove or delete it.
11. Click **Next**.
12. Enter the following *Collect event data* information:
    - **Enable data collection**: Enable the toggle button if required.

- **Types of events**: Select one or more event types for data collection from the following options:
    - Incidents
    - Issues
    - Changes

13. Click **Next**.
14. Enter the following *Collect metric data* information to define how you want to collect metric data. Topology metric data that is related to applications, endpoints, and services can be enabled and thus collected, or indeed disabled.

    - **Enable data collection**: Set the toggle button to 'on'.
    - **Monitored metrics**: You can select built-in metrics to monitor. These metrics are categorized by the technologies that they are associated with. You can also add custom-defined metrics to monitor. To select metrics, use any of the following options:
        - Enter your preferred metrics in the search bar and select their corresponding checkboxes.
        - Search and select your preferred technologies and their associated metrics in their respective filter table. To find the related metrics of a technology, click its corresponding arrow. By default, all metrics of the chosen technologies are selected.
        - Select the **Start from recommended metrics** checkbox if you are not sure which metrics to start with. This option selects all recommended technologies and their associated metrics in the filter table.
        - Clear the selected checkboxes to undo any selection. However, if you clear the **Start from recommended metrics** checkbox, all current selection is cleared.
        - All selected metrics are listed in the **Selected metrics** list. You can remove any listed metric by clicking the **Deselect Metric** icon corresponding to it.
        - You might see performance issues or gaps in your data due to the number of metrics selected. To avoid this problem, consider starting with the set of recommended metrics or those that are most important for you to monitor.

15. Click **Next**.
16. Enter the following *Metric data summary* information:

    - **Selected metrics**: The table lists all the selected technologies and metrics. You can remove any metrics from the list. To remove a listed metric, select the checkbox corresponding to it and click **Remove**.
    - **Only collect Live Data once the integration is established**: Select the checkbox to enable live data collection. **Note**: If you choose to collect only live data, you cannot collect historical data after the live data collection starts.
    - **Scheduled collection interval (minutes)**: Enter a value in minutes. This value is the frequency at which data is collected.
    - **Historical data collection**: The recommended time period for collecting historical metric data is two weeks, though it is possible to collect it for up to 31 days. Enter a start and end date and time in the following formats:
        - *Start date and time**: Select the start date from the calendar and enter the time in the 'hh:mm' format (hours and minutes).

          Note: Your start date should not exceed 31 days from the present.

        - **Time zone**: Select your time zone from the dropdown list.

        - **End date and time**: Click **Add end date** and select a date from the calendar. Also, enter the time in the 'hh:mm' format (hours and minutes). If you don't want to set an end date at this stage, click **Remove End Date**.

        - **Scheduled collection interval (minutes)**: Enter a value in minutes. This value is the frequency at which data is collected.

          Note: If you do not select an end date, IBM Cloud Pak for AIOps collects historical data from the specified start date and continues with live data collection. You cannot collect historical data after live data collection starts.

          Note: If you have already set an end date and time for an Instana integration, you cannot edit it. If you need to edit either of these properties, you must delete your integration and create a new one.

17. Click **Done**.

For more information about performance considerations for metric data collection, see Performance considerations for metric data collection.

You have created an *Instana* integration in your instance.

After the integration creation is complete, and if you selected the *Remote* option for integration deployment, you can download the *bootstrap script*. Select the created integration, and then click **download** from the options menu (three vertical dots). If a script is regenerated, it invalidates the credentials of previously downloaded scripts for that integration.

Note: You can either copy the script or download as an sh file to run it on a remote cluster.

Prerequisites before you run the bootstrap script on a remote cluster

- Podman needs to be installed on the remote cluster.
- Log in to the *Image registry* for the script to pull in the image by using the Podman login command.

After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling Instana integrations.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

For Instana on-prem installation, the recommended rate limit is double the number of resources. This limit is enough to cover most cases, although situations might arise where the limits need to be increased even more. When a more precise way to determine the limit is required (for instance a shared multi-tenant SaaS environment), the following formula can be applied:

```
number-of-metric-API-calls-per-hour ~= (number-of-selected-technologies x 2) x (snapshots-for-selected-technologies / 30)
x (60 / collection-interval)
number-of-topology-API-calls-per-hour ~= (number-of-application-perspectives x (60 / collection-interval)) +(number-of-
```

```
services x (60 / collection-interval))
number-of-events-API-calls-per-hour = 60

total= number-of-metric-API-calls-per-hour + number-of-topology-API-calls-per-hour + number-of-events-API-calls-per-hour
```

Note: This formula is not always 100% accurate, as each technology or plug-in has a different number of metrics collected (the mean value across these is used, which is 2 collection cycles or technology). If the environment is unbalanced toward either end of the spectrum (for instance, if you have mostly hosts that define the most metrics), then the formula might underestimate the required limit.

To determine the number of resources (snapshots) for each infrastructure pluginAPI, you can use the following:

```
api/infrastructure-monitoring/snapshots?plugin=technology_name
```

Example:

```
api/infrastructure-monitoring/snapshots?plugin=host
```

For more information about Instana APIs, see Instana API.

With the following example curl commands, you can retrieve the number of the following resources:

- `snapshots-for-selected-technologies` (such as host)

  ```
  curl -k -s --request GET 'https://<instana server hostname>/api/infrastructure-monitoring/snapshots?plugin=host' --header 'Authorization: apiToken <api token>' | jq '.items|length'
  ```

- `number-of-application-perspectives`

  ```
  curl -k -s --request GET 'https://<instana server hostname>/api/application-monitoring/applications' --header 'Authorization: apiToken <api token>' | jq '.items|length'
  ```

- `number-of-services`

  ```
  curl -k -s --request GET 'https://<instana server hostname>/api/application-monitoring/services' --header 'Authorization: apiToken <api token>' | jq '.items|length'
  ```

Enabling and disabling Instana integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Instana** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect topology data* section. Enable the toggle button if required.
6. Go to the *Collect event data* section. Enable the toggle button if required.
7. Go to the *Collect metric data* section. Enable the toggle button if required.

Note: Disabling data collection for an integration does not delete the integration.

You have enabled or disabled your integration. For more information about deleting an integration, see Deleting Instana integrations.

Editing Instana integrations

After you create your integration, you can edit it. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Instana** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Instana integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

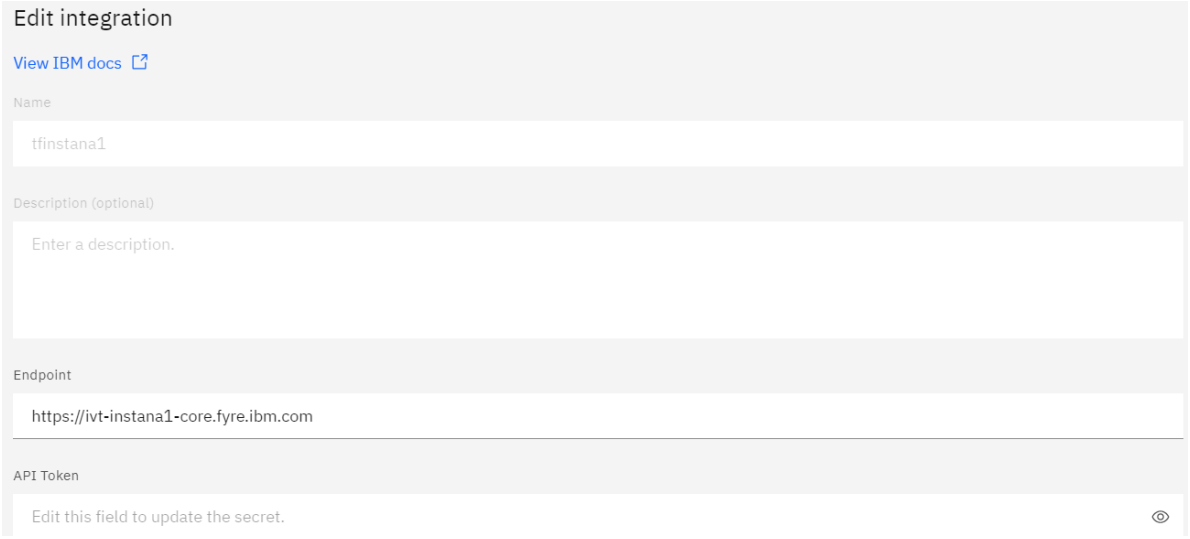

Figure. Edit Instana integration

You have edited your integration. If you have not previously enabled or disabled your application, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Instana integrations. For more information about deleting an integration, see Deleting Instana integrations.

Deleting Instana integrations

If you no longer need your Instana integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Instana** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Instana integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating Jira integrations

You can integrate with Jira to enable connectivity to Jira tickets. This enables you to view the resolutions for Jira incidents within IBM Cloud Pak for AIOps based on the similar Jira tickets. You can also get Jira issues created for incidents in IBM Cloud Pak for AIOps, update the incident in AIOps, and get the same update in the corresponding Jira issue.

For more information about working with Jira integrations, see the following sections:

- Before you begin
- Best practices
- Creating Jira integrations
- Enabling and disabling data flow in Jira integrations
- Editing Jira integrations
- Deleting Jira integrations

Before you begin

Ensure that you have following information to hand:

- Domain of the Jira instance
- Key for the Jira project
- User name to access the Jira server
- Password or API token for the Jira server
- Jira issue type
- Final state of the Jira issue

Best practices

- When creating multiple Jira connectors, use a different username and token to facilitate speedier data collection.

- Use a personal access token that does not expire.
- When Historical data collection is selected, select a start date close to the date that will be used for AI training. Selecting a date further back might result in more API calls to Jira, especially if there is a large volume of issues.

Creating Jira integrations

To create an Jira integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Jira** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **Domain of Jira instance**: Enter the domain of your Jira instance, for example `https://<your-environment-id>.atlassian.net`.
   - **Jira project key**: Enter the key for Jira project that contains your tickets.
   - **User name to access Jira server**: Enter the name of a Jira user that has permissions to create and manage tickets in the specified project.
   - **Password or API token**: +Enter the password or personal access token that IBM Cloud Pak for AIOps will use when calling the Jira APIs.
7. Click **Test connection**. It is best to wait for the test to succeed before continuing to the next step. This can take some time.
8. Click **Next**.
9. Use the *Field mapping* page to map IBM Cloud Pack for AIOps incident fields to Jira ticket fields. You can use the default template, or you can customize it to suit your environment.

   Note: To customize the mapping, copy the text out of the mapping textbox and into your preferred text editor. Then add the mapping for your fields. When done, copy the text back into the mapping textbox.

   The following example maps the states that are in the `statusMap`. `Keys` are the IBM Cloud Pak for AIOps states and `values` are Jira states. You can set the status using the `statusMap` as shown below:

   ```
   (
   $statusMap := {
   "resolved": "Resolved",
   "inProgress": "In Progress",
   "assigned": "To Do",
   "closed": "Done"
   };
   {
       "summary": $string(incident.title),
       "description": $join(["Incident Id:", $string(incident.id),
                         "\nAIOPS Incident Overview URL: https://", $string(URL_PREFIX), "/aiops/default/resolution-
   hub/incidents/all/", $string(incident.id), "/overview",
                         "\nStatus: ", $string(incident.state),
                         "\nDescription: ", $string(incident.description)]),
       "labels": [$join(["priority:", $string(incident.priority)])],
       "assignee": $string(incident.owner),
       "status": $statusMap[$string(incident.state)] ? $statusMap[$string(incident.state)] : $string(incident.state)
   })
   ```

   You must enter the following information on this page according to your Jira project settings:
   - **Issue type for Jira**: Enter the type of issue that will be created in Jira. The default value is `Task`.
   - **Final state of Jira issue**: Enter the final state of the Jira issue that contains the incident. The default value is `Done`.
10. Click **Next**.
11. Enter the following *Collect ticket data* information:
    - **Data collection**: Enable the toggle button.
    - **Mode**: Select one of the following options:
      - **Live - Continuous Similar Tickets training**
      - **Historical - Initial Similar Tickets training**
    - **Jira issue sampling rate**: Specify the frequency (in minutes) at which data is sampled for Jira issues.
12. Click **Done**.

You have created a *Jira* integration in your instance.

Using a policy to open a Jira ticket

When the Jira integration is up and running, you can create a policy that opens an incident within Jira by selecting the integration from the *Open a ticket* area of your *Promote alerts to an incident* policies. See **Steps 12** and **13** of Promote alerts to an incident.

Enabling and disabling data flow in Jira integrations

If you did not enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Jira** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect ticket data* section. Enable the toggle button if required.

Note: Disabling data collection for an integration does not delete the integration.

You have enabled or disabled your integration. For more information about deleting an integration, see Deleting Jira integrations.

Editing Jira integrations

After you create your integration, you can edit it. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Jira** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Jira integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

You have edited your integration. If you have not previously enabled or disabled your application, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Jira integrations. For more information about deleting an integration, see Deleting Jira integrations.

Deleting Jira integrations

If you no longer need your Jira integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Jira** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Jira integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating Kafka integrations

A Kafka integration can provide either event or log data. Log data can be used to establish a baseline of normal behavior and then identify anomalies. Event data enables the analysis and processing of different types of alerts and events. Anomalies that are identified can be correlated with alerts and events and published to your ChatOps interface to help you determine the cause and resolution of a problem.

Custom integrations can route only a single source of data at one time. Unlike the custom integration type, you can use the Kafka integration type to collect log data and event data from different systems. Then, you can route that information through a forwarding agent, such as an Apache Kafka topic like Sysdig or FluentBit.

You can also use the Kafka integration to enable training with an offline, historical data set. For more information about using Kafka topics for offline training, see Importing offline log data.

Notes:

- The Kafka replication factor is set to one replica by default. If you are implementing a production deployment of IBM Cloud Pak for AIOps, you might lose data if your Kafka pods fail or restart. If the data collection is enabled in your Kafka integration when the Kafka pods go down, you might experience a gap in the data that your integration generated during that down period.
- The maximum Kafka message size limit in Cloud Pak for AIOps is `1048588` bytes.
- If you frequently send in messages that are close to the maximum size, it can adversely impact the performance.

For more information about working with Kafka integrations, see the following sections:

- Creating Kafka integrations

- Enabling Kafka integrations
- Editing Kafka integrations
- Importing offline log data
- Deleting Kafka integrations

Creating Kafka integrations

Unlike other integration types, you can use Kafka integrations to push properly formatted historical training data to IBM Cloud Pak for AIOps. To create a Kafka integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Kafka** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your Kafka integration.
   - **Description**: An optional description for the Kafka integration.
   - **Kafka partitions**: The number of Kafka partitions. The default value of `1` might be suitable for importing a few log records. However, if you intend to import many records, increase this number. The range is `1` to `500`. For example, for a proof of content (PoC) deployment where you need to import a large data set, you can use `48` Kafka partitions.
   - **JSON processing option**: Select a JSON processing option.
     - **None**: The default option. The JSON is not processed or modified.
     - **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
     - **Filter**: This option extracts the JSON object and replaces it with an empty string.

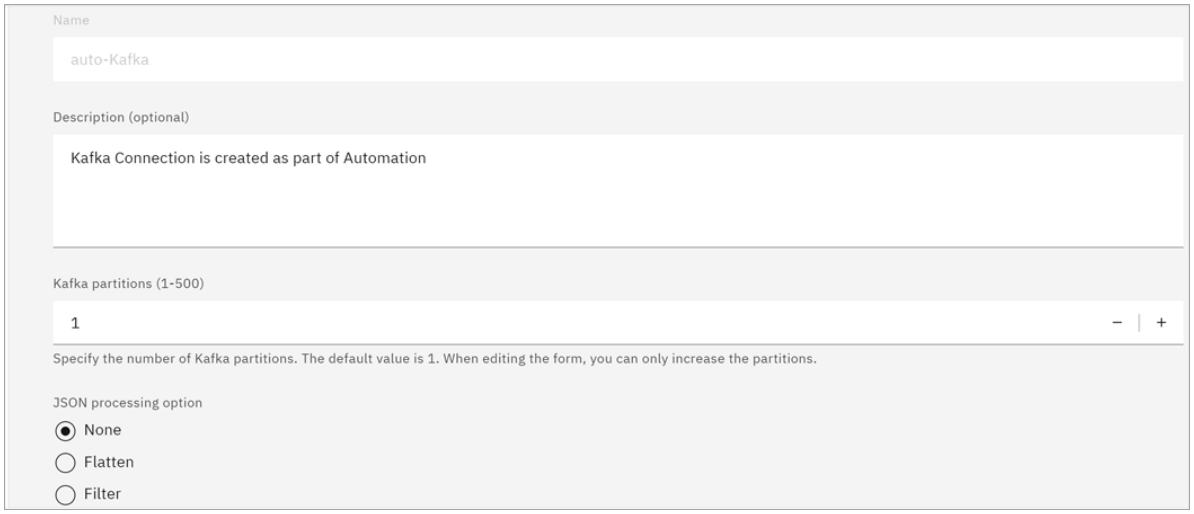

Figure. Create Kafka integration

   For more information about the options, see Managing embedded JSON.
7. Click **Next**.

Entering Field mapping information

Unlike other integration types, you can specify what kind of information you want to run through your Kafka integration. For example, if you want to collect data from multiple custom sources, you can set them up as separate Kafka integrations.

1. In the **Field mapping** section, set the **Data source** to specify the type of data incoming from the Kafka integration. You can select **Events** or **Logs**.
2. Specify the **Mapping type**, which creates the field mapping for your specified log type.
   - Mapping types for **Events** include **None**, **PagerDuty**, and **NOI**.
   - Mapping types for **Logs** are **None**, **ELK**, **Falcon LogScale**, **Mezmo**, **Custom**, and **Splunk**.
   - If you have log data that is already normalized, choose **None**.

- If your log data is in one of the supported log formats, such as ELK or Falcon LogScale, choose the corresponding log format.
- For field mapping for **Custom** types, see Creating custom integrations.

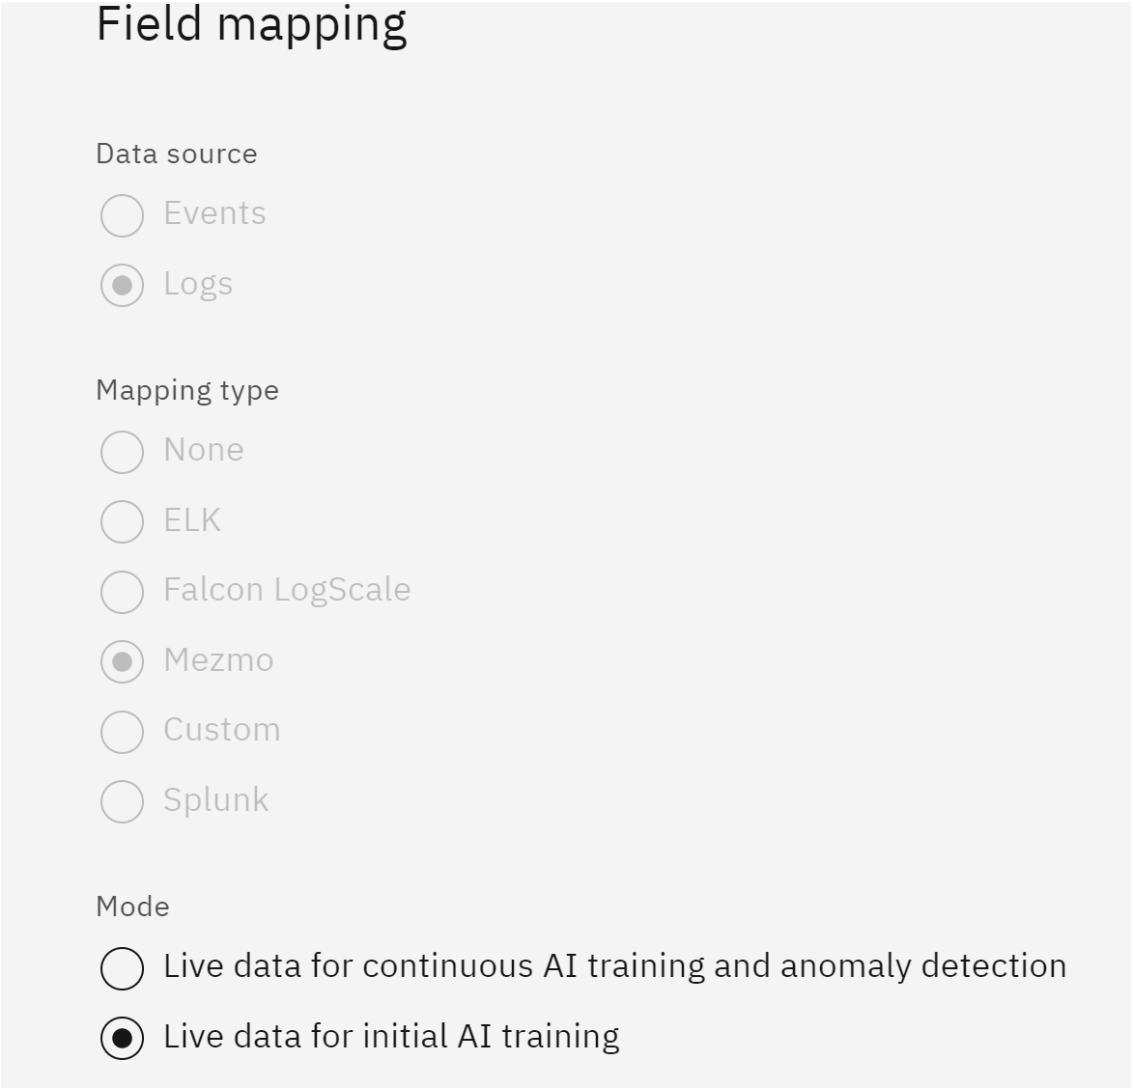

Figure. Field mapping type

3. The **Topic** name for a Kafka integration is predefined. Note this topic and send your data to it.
4. For log integrations, complete the following settings:
    1. Enter the **Maximum number of logs per second** rounded to the nearest thousand. The maximum number of logs per second is collected in increments of 1,000 up to 25,000 and is rounded up to the nearest thousand sent from Kafka to IBM Cloud Pak for AIOps.
    2. Set the **Field mapping** mode to **Live data for initial AI training** for initial training or to **Live data for continuous AI training and anomaly detection**.

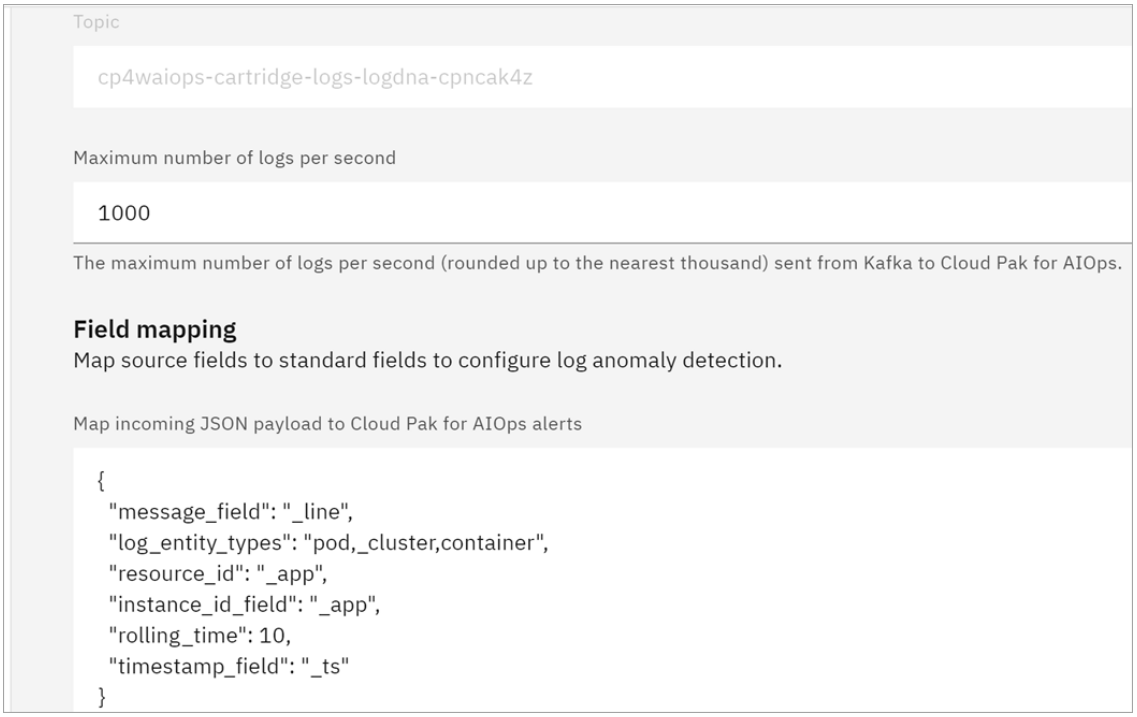

Figure. Field mapping

- You can improve search performance by mapping the fields from your implementation fields to standard IBM Cloud Pak for AIOps fields. For more information about how field mappings are defined, see Mapping data from incoming sources.
- For more information about using mappings to clean your data for use in IBM Cloud Pak for AIOps, see Cleaning mapped data using regular expressions.

3. In the **Mapping** section, if you use a **Mapping type** other than **None**, verify whether the JSON document that is automatically assigned to this field is valid. The validity depends on the structure of your log records. For example, for a PoC deployment, an example default **Field mapping** for Kafka can resemble the following mapping:

```
{
  "codec": "elk",
  "message_field": "@message",
  "log_entity_types": "@hostname, @bundleName, @context.Environment",
  "instance_id_field": "@properties.processtype",
  "rolling_time": 10,
  "timestamp_field": "@timestamp"
}
```

If you chose **None** for the **Mapping type**, each log record in your log files conforms to the following format. Set both of the `application_id` and `application_group_id` values to `"1000"`, and make sure that a 13-digit timestamp value is assigned to the `timestamp` field:

```
{
    "timestamp": 1581549409000,
    "utc_timestamp": "2020-02-12 23:16:49.000",
    "instance_id": "calico-node-jn2d2",
    "application_group_id": "1000",
    "application_id": "1000",
    "features": [],
    "meta_features": [],
    "level": 1,
    "message": "[64] ipsets.go 254: Resyncing ipsets with dataplane. family=\"inet\"",
    "entities": {
        "pod": "calico-node-jn2d2",
        "cluster": null,
        "container": "calico-node",
        "node": "kube-bmgcm5td0stjujtqv8m0-ai4itsimula-wp16cpu-00002c34"
    },
    "type": "StandardLog"
}
```

Important: The **Events** data that is collected must follow the **Kafka integration normalized Event schema**. For more information, see Normalized mapping rules.

5. Click **Next**.

Note: When importing events the JSON structure for an event must be on a single line in the file. For more information about the structure for importing event data, see Normalized Mapping Rules.

Entering AI training and log data information

1. If you want to enable data collection for AI training and log data, switch the **Data collection** toggle to **On**.

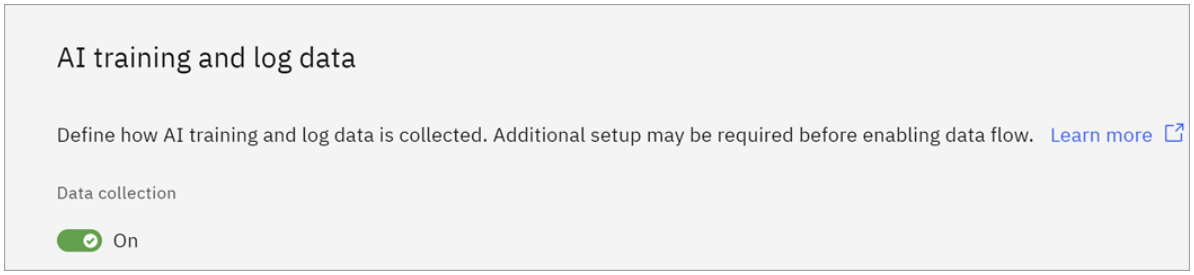

Figure. AI training

2. Click **Next**.
3. The UI displays the *Resource requirements* page.

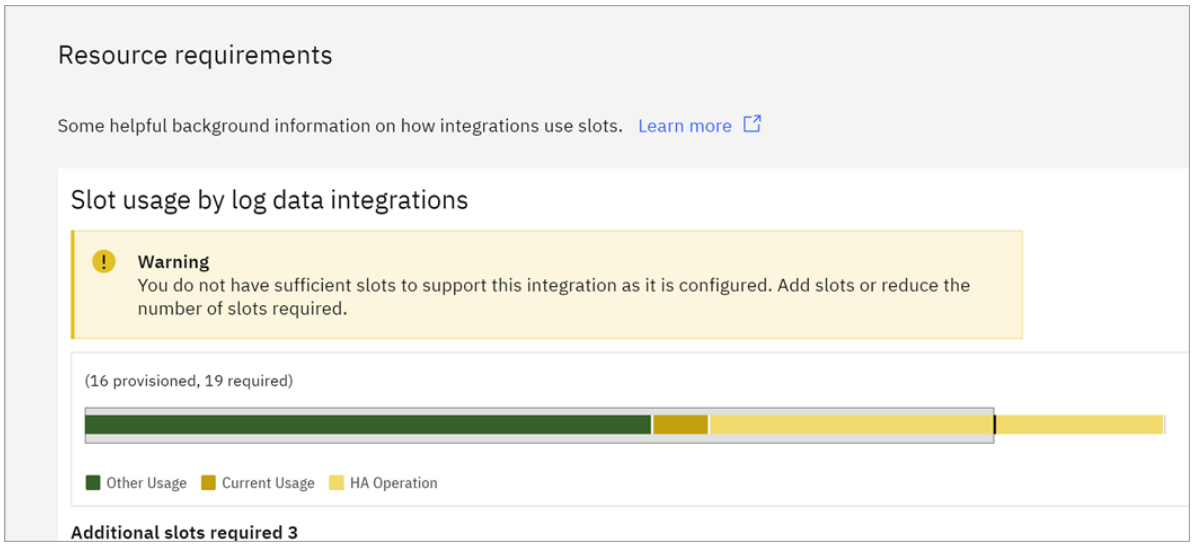

Figure. Resource requirements

Note: If the **Data Source** is set to **Events**, you will see a message stating that you need to enable logs data collection to see the resource management overview. You can skip this page when events are enabled.

On the *Resource requirements* page, you can review the slot usage for your log integrations to see if there are enough slots to fully support the integration for multizone high availability.

If you set the **Data collection** toggle to **On**, you will see the resource management overview.

- If your current usage and other usage are less than the provisioned slots, but the HA slots exceed the provisioned slots, you will be able to create the integration, but will see a warning that you do not have enough slots. The integration will not have multizone high availability.
- If your projected usage exceeds the provisioned slots, you will not be able to create the integration because you do not have enough slots on your system for log data integrations.
- If your total slots, including HA slots, are within the provisioned slots, the integration will have multizone high availability.

  Note: HA operation assumes high availability for three zones.

If you set the **Data collection** toggle to **Off**, you will see a message stating that you need to enable logs data collection to see the resource management overview. When data collection is off, no slots are used by that integration.

4. Click **Done** to save your integration.

You created a Kafka integration in your instance, and you can now use the Kafka integration as the basis for your offline AI model training. After you create your integration, enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps.

- For more information about enabling your integration, see Enabling Kafka integrations.
- To create more integrations, such as a ChatOps integration, see Configuring Integrations.
- For more information about working with the insights provided by your integrations, see ChatOps insight management.
- For more information about AI model training, see Configuring AI models.

Importing offline log data

Before you proceed with the following steps, make sure that the data flow is enabled for the Kafka Ops integration that you previously defined. You can import offline log data into IBM Cloud Pak for AIOps in two ways. Both mechanisms publish the offline log data to the Kafka topic that is associated with the Kafka Ops integration.

Using a Kafka utility to publish log data

1. Install a Kafka utility, such as the kcat utility.

2. Log in to the Red Hat® OpenShift® cluster where IBM Cloud Pak for AIOps is installed.
3. Run the following commands from the namespace where IBM Cloud Pak for AIOps is installed:

```
oc extract secret/iaf-system-cluster-ca-cert --keys=ca.crt --to=- > ca.crt

export sasl_password=$(oc get secret cp4waiops-cartridge-kafka-auth-0 --template={{.data.password}} | base64 --
decode);

export BROKER=$(oc get routes iaf-system-kafka-bootstrap -o=jsonpath='{.status.ingress[0].host}{"\n"}'):443
```

4. Publish the log data to the Kafka topic. This example uses kcat. If you also use kcat, update the variables and run the following commands:

```
export KAFKA_TOPIC=<kafka topic>

export LOG_FILE=<log file>

kcat -X security.protocol=SASL_SSL -X ssl.ca.location=ca.crt -X sasl.mechanisms=SCRAM-SHA-512 -X
sasl.username=cp4waiops-cartridge-kafka-auth-0 -X sasl.password=$sasl_password -X
enable.ssl.certificate.verification=false -b $BROKER -P -t $KAFKA_TOPIC -l $LOG_FILE
```

Copying log data into the Kafka cluster

Use this option only if you can't use a Kafka utility such as kcat for your environment. Complete the following steps to publish the log data to the corresponding Kafka topic by copying the log data into the Kafka cluster:

1. Run the following commands from the namespace where IBM Cloud Pak for AIOps is installed to obtain the Kafka password and Kafka broker. Record both values, which you need in a following step.

```
export kafka_password=$(oc get secret cp4waiops-cartridge-kafka-auth-0 --template={{.data.password}} | base64 --
decode)

export kafka_broker=$(oc get routes iaf-system-kafka-bootstrap -o=jsonpath='{.status.ingress[0].host}{"\n"}'):443

echo $kafka_password

echo $kafka_broker
```

2. Copy the log file to the Kafka cluster:

```
oc cp <log file> iaf-system-kafka-0:/tmp
```

3. Check that the file is copied to the Kafka cluster from the namespace where IBM Cloud Pak for AIOps is installed:

```
oc exec -it iaf-system-kafka-0 -- bash

ls /tmp/<log file>

exit
```

4. Get the `ca.cert` certificate file:

```
oc extract secret/iaf-system-cluster-ca-cert --keys=ca.crt --to=- > ca.crt
```

5. Convert `ca.crt` to Java keystore format (JKS):

```
keytool -import -trustcacerts -alias root -file ca.crt -keystore truststore.jks -storepass password -noprompt
```

6. Copy the truststore file to the Kafka cluster:

```
oc cp truststore.jks iaf-system-kafka-0:/tmp
```

7. Give bash access to the Kafka cluster again:

```
oc exec -it iaf-system-kafka-0 -- bash
```

8. Create a file within the Kafka pod that is called `producer.properties`. The contents of the `producer.properties` file can resemble the following properties. Update the `variable placeholders` before you use this content. The `ssl.truststore.location` value points to the JSK file that you created earlier.

```
security.protocol=SASL_SSL
ssl.truststore.location=/tmp/truststore.jks
ssl.truststore.password=password
sasl.mechanism=SCRAM-SHA-512
sasl.jaas.config=org.apache.Kafka.common.security.scram.ScramLoginModule required \
username="cp4waiops-cartridge-kafka-auth-0" \
password="<kafka password>"
```

9. From the pod, run the Kafka producer script to publish the log data to the corresponding Kafka topic. Update the `variable placeholders`:

```
/opt/Kafka/bin/Kafka-console-producer.sh --broker-list <kafka broker> --producer.config producer.properties --topic
<kafka topic> < <log file>
```

Enabling and disabling Kafka integrations

If you didn't enable your data collection during creation, you can enable your integration after. You can also disable a previously enabled integration the same way. If you selected **Live data for initial AI training** when you created your integration, disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Kafka** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section. Set **Data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting Kafka integrations.

Editing Kafka integrations

After you create your integration, you can edit the integration. For example, if you want to refine the field mapping for a Kafka integration from a Falcon LogScale source, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Kafka** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Kafka integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Kafka integrations. For more information about deleting a integration, see Deleting Kafka integrations.

Deleting Kafka integrations

If you no longer need your Kafka integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before you delete your integration. For more information about disabling data collection, see Enabling and disabling Kafka integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Kafka** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Kafka integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Connecting with Metric Manager

To integrate Metric Manager (formerly IBM® Operations Analytics Predictive Insights) with IBM Cloud Pak for AIOps , first ensure that you implement the prerequisites, and then change the rules file in Metric Manager.

Note: IBM Cloud Pak for AIOps comes with built-in metric capabilities. Connect with Metric Manager only if these capabilities are insufficient to your needs.

Prerequisites

To allow the forwarding of event data from Metric Manager to IBM Cloud Pak for AIOps , and the integration of both, do the following:

1. Event forwarding from Metric Manager to IBM Cloud Pak for AIOps is done by forwarding from the on-premises objectserver to IBM Cloud Pak for AIOps by using a uni-directional gateway. To set up this gateway, follow the instructions described here.
2. For Metric Manager 1.3.6 integration with IBM Cloud Pak for AIOps , apply InterimFix005 available here.

Procedure

Change the rules file in Metric Manager. Make the following changes to the rules file (located here: $PI_HOME/probe/omnibus/probes/linux2x86/stdin-tasp.rules) in Metric Manager.

Note: Ensure you backup the rules file before you edit the file.

1. In the file, locate the following two lines:

```
#@Identifier = @Node + " " + @AlertKey + " " + @AlertGroup + " " + @Type + " " + @Agent + " " + @Manager
@Identifier = $Identifier
```

Remove the '#' from the first line and add it to the start of the second, so that it changes to the following:

```
@Identifier = @Node + " " + @AlertKey + " " + @AlertGroup + " " + @Type + " " + @Agent + " " + @Manager
#@Identifier = $Identifier
```

2. Add the following before the last closing bracket "}", replacing "PI_UI_HOST.example.com=" with the fully qualified domain name of the Metric Manager UI host:

```
@URL = "https://PI_UI_HOST.example.com:9998/predictiveinsights/jsp/wlp/wlpAnomalyView.jsp?anomalyKey=" +
$TASPIdentifier
update(@URL)
```

3. Add either of the following just after the last closing bracket "}":

   - IBM Cloud Pak for AIOps

```
#For integration with IBM Cloud Pak for AIOps :

if (regmatch($Class, "89350") || regmatch($Class, "89360")) {
   @AlertGroup = "ANOMALY:" + @TASPAnomalousMetricGroups + ":" + @TASPAnomalousMetrics
   update(@AlertGroup)
   }

   ## Note: Do not forward these consolidated events from Metric Manager, as the downstream system will do this
grouping:

   if (regmatch($TASPIdentifier, "Node") || regmatch($TASPIdentifier, "RelatedEvents") ||
regmatch($TASPIdentifier, "Incident")) {
  discard
  }
```

   - IBM Cloud Pak for AIOps Event Manager

```
#For integration with IBM Cloud Pak for AIOps Event Manager

if (regmatch($Class, "89350") || regmatch($Class, "89360")) {
   @AlertGroup = "ANOMALY:" + @TASPAnomalousMetricGroups + ":" + @TASPAnomalousMetrics
   update(@AlertGroup)
   }
   $Identifier = regreplace($Identifier, "(_\d{13}$)", "" )
   @Identifier = $Identifier
   update(@Identifier)

   ## Note: Do not forward these consolidated events from Metric Manager, as the downstream system will do this
grouping:

   if (regmatch($TASPIdentifier, "Node") || regmatch($TASPIdentifier, "RelatedEvents") ||
regmatch($TASPIdentifier, "Incident")) {
  discard
  }
```

4. To start the gateway, run the following:

```
cd /opt/IBM/tivoli/netcool/omnibus/bin
nohup ./nco_g_objserv_uni -name NCO_GATE -propsfile /opt/IBM/tivoli/netcool/omnibus/gates/aiops/aiops.props &
```

Creating Mezmo integrations

A Mezmo integration provides log data, which is used to establish a baseline of normal behavior and then identify anomalies. These anomalies can be correlated with other alerts and events, and published to your ChatOps interface to help you determine the cause and resolution of a problem.

For more information about working with Mezmo integrations, see the following sections:

- Creating Mezmo integrations
- Enabling Mezmo integrations
- Editing Mezmo integrations
- Deleting Mezmo integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating Mezmo integrations

The Mezmo integration type collects data from a Mezmo data source.

About this task

Before you create a integration, gather the following information:

- **Load**: To prevent the integration from placing an inordinate load on your data source and potentially impacting your logging operations, the integration connects to only one API with a default data frequency of 60 seconds. This restriction is controlled by using the **Sampling rate** setting in the Procedure

section.

- **Access:** Mezmo data sources are cloud-based and use a service key approach to enable access.
- **Data volume**: Typical data volumes are as follows:
  - 5.5 MB (15000 lines) for 20 seconds on Development environment.
  - 49 logs (19 KB) in a 10-second interval. Pulled within 30 seconds.
  - 10 logs (3.2 KB) in a 10-second interval. Pulled within 30 seconds.
  - 195 logs (75 KB) in a 30-second interval. Pulled within 60 seconds.

Procedure

To create a Mezmo integration, step through the following sections:

- Adding a Mezmo integration
- Specifying integration parameters
- Specifying field mapping
- Specifying how log data is collected for AI training

Adding a Mezmo integration

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Mezmo** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.

Specifying integration parameters

1. On the *Add integration* page enter the following integration information:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **URL**: The hostname or IP address of the Mezmo API. To find the URL, log in to your Mezmo account or check the Mezmo instance in your IBM Cloud account. For more information, see the Log Analysis documentation about Endpoints.
   - **Service key**: The Mezmo service key. For more information, see Service keys.

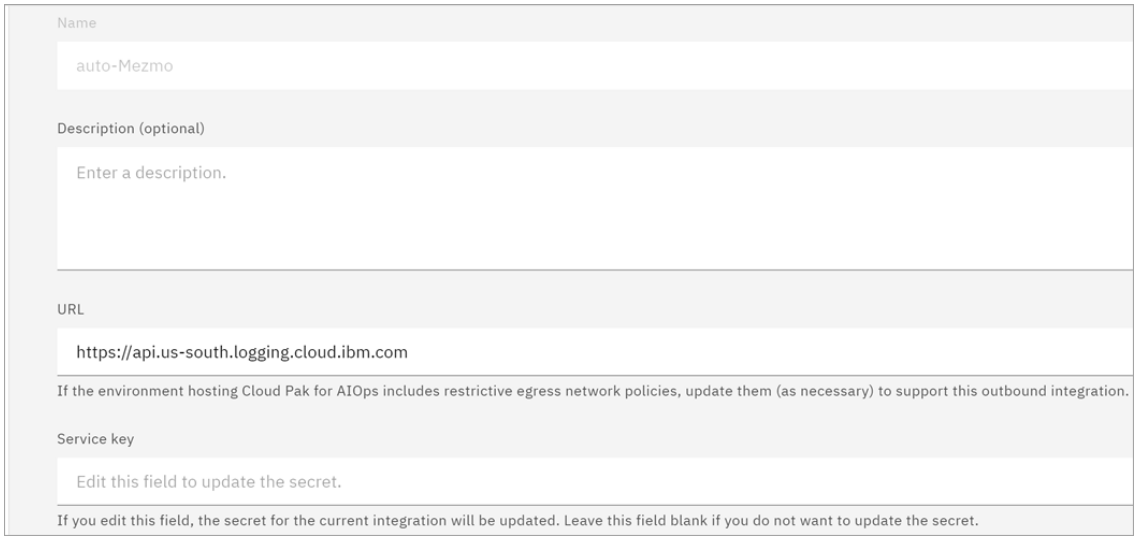

Figure. Create Mezmo integration

   - **Certificate**: An optional certificate used to verify the SSL/TLS connection to the REST service.
   - **Filters**: Defines subsets of data that is pulled from Mezmo. For example, `healthcheck (successful OR ping)` returns all of the log lines with the word `healthcheck` and without the word `successful`, and all of the log lines with the word `healthcheck` and with the word `ping`. For more information about Mezmo filtering, see Search and Filter Log Data documentation.
   - **Base parallelism**: Select a value to specify the number of Flink jobs that can run in parallel. These jobs run to process and normalize the collected data. The default value is 1. However, it is recommended to use a higher value than 1 so that you can process data in parallel. This value cannot exceed the total available free Flink slots. In a small environment, the available flinks slots are 16, while in a large environment, the maximum available slots are 32. If you are collecting historical data with this integration, you can set this value to be equal to the **source** parallelism.

- **Sampling rate**: The rate at which data is pulled from the live source (in seconds). The default value is **60**.
- **JSON processing option**: Select a JSON processing option.
  - **None**: The default option. The JSON is not processed or modified.
  - **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
  - **Filter**: This option extracts the JSON object and replaces it with an empty string.

For more information about the options, see Managing embedded JSON.

2. Click **Test connection**.

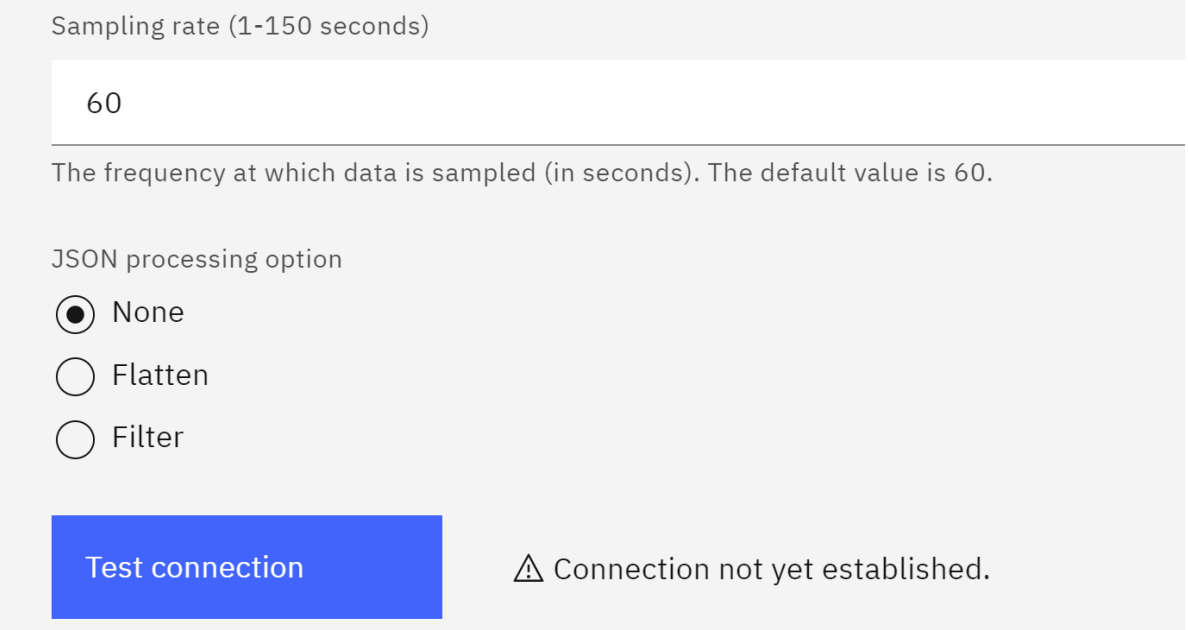

Figure. Test connection

Note: To improve data throughput, you can increase the base parallelism value incrementally. For more information about maximum base parallelism for starter and production deployments, see Improving data streaming performance for log anomaly detection.

3. Click **Next** to move to the next page.

Specifying field mapping

1. On the *Field mapping* page you can improve search performance by mapping the fields from your implementation fields to standard fields within IBM Cloud Pak for AIOps.

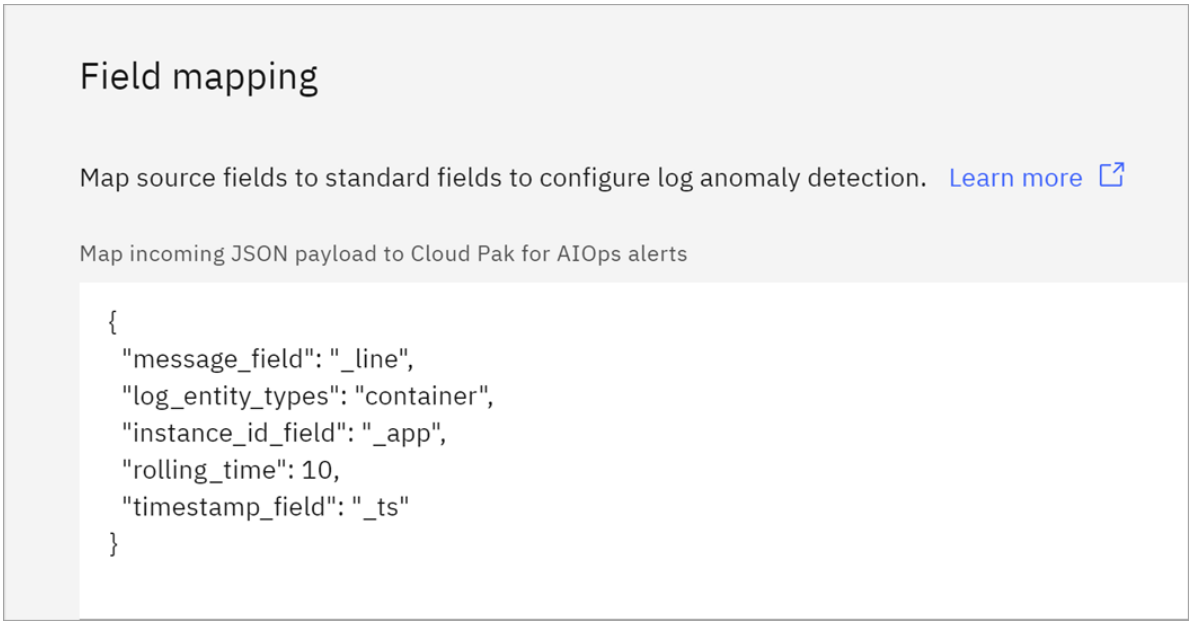

Figure. Field mapping

- For more information about how field mappings are defined, see Mapping data from incoming sources.

- For more information about using mappings to clean your data for use in IBM Cloud Pak for AIOps, see Cleaning mapped data using regular expressions.

The following code snippet displays an example of field mapping by using the supported format. When coding your mapping, use this example to help you.

```
{
  "codec": "mezmo",
  "rolling_time": 10,
  "instance_id_field": "_app",
  "log_entity_types": "container",
  "message_field": "_line",
  "timestamp_field": "_ts"
}
```

You can also map from a nested field in the source data to a field in IBM Cloud Pak for AIOps data. For example, in the following code snippet, the line `"message_field": "_line.message",` maps the field `message_field` in IBM Cloud Pak for AIOps data to the nested field `_line.message` in the Mezmo data.

```
{
 "rolling_time": 10,
 "instance_id_field": "_app",
 "log_entity_types": "container",
 "message_field": "_line.message",
 "timestamp_field": "_ts"
}
```

You can also create an OR relationship between multiple nested fields, where the OR relationship is expressed by using a semicolon. For example, in the following code snippet, the line `"message_field": "_line.message1;_line.message2;_line.message3",` maps the field `message_field` in IBM Cloud Pak for AIOps data to one of three possible nested fields in the Mezmo data:

- `_line.message1`, or
- `_line.message2`, or
- `_line.message3`
  - The system first looks for `_line.message1` in the Mezmo data record, and if it finds this field, then it uses it for the mapping.
  - If it can't find `_line.message1` in the Mezmo data record, then it looks for the next item `_line.message2` and if it finds it, then it uses it for the mapping.
  - If it can't find `_line.message2` in the Mezmo data record, then it looks for the next item `_line.message3` and if it finds it, then it uses it for the mapping.

```
{
  "rolling_time": 10,
  "instance_id_field": "_app",
  "log_entity_types": "container",
  "message_field": "_line.message1;_line.message2;_line.message3",
  "timestamp_field": "_ts"
}
```

2. Click **Next** to move to the next page.

Specifying how log data is collected for AI training

1. On the *AI training and log data* page, select how you want to manage collecting data for use in AI training and anomaly detection. Click the *Data flow* toggle to turn on data flow and then select how you want to collect data:

   - **Live data for continuous AI training and anomaly detection**: A continuous collection of data from your integration is used to both train AI models and analyze your data for anomalous behavior.

     Note: After an initial installation, there is no data at all in the system. If you select this option, then the two different log anomaly detection algorithms behave in the following ways:

     - Natural language log anomaly detection does not initially detect anomalies as no model has been trained. You can retrieve historical data (select **Historical data for initial AI training**) to speed up the retrieval of data to train on, or you can leave the **Live data for continuous AI training and anomaly detection** setting on. In the latter case, the system gathers training data live and after a few days there is enough data to train a model. When this model is deployed, then it detects anomalies as normal.
     - Statistical baseline log anomaly detection does not detect anomalies for the first 30 minutes of data collection. This is because it does not have a baseline yet. After 30 minutes of live data collection the baseline is automatically created. After that it detects anomalies on an ongoing basis, while continuing to gather data and improve its model every 30 minutes.

   - **Live data for initial AI training**: A single set of training data used to define your AI model. Data collection takes place over a specified time period that starts when you create your integration.

     Note: Selecting this option causes the system to continue to collect data while the option is enabled; however, the data is collected for training only, and not for log anomaly detection. For more information about AI model training, including minimum and ideal data quantities, see Configuring AI training.

   - **Historical data for initial AI training**: A single set of training data used to define your AI model. You must specify a Start and End date, and the parallelism of your source data. Historical data is harvested from existing logs in your integration over a specified time period in the past.
     - **Start date**: Select a start date from the calendar.

Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.

- **End date**: Select an end date from the calendar.

  Note: If you do not specify the end date, then live data collection follows the historical data collection. If you do not want to set an end date, click **Remove end date**.

- **Source parallelism (1-50)**: Select a value to specify the number of requests that can run in parallel to collect data from the source. Generally, you can set the value to equal the number of days of datat that you want to collect. When you are setting this value, consider the number of requests that are allowed by the source in a minute. For example, if only 1-2 requests are allowed, set the value to be low.

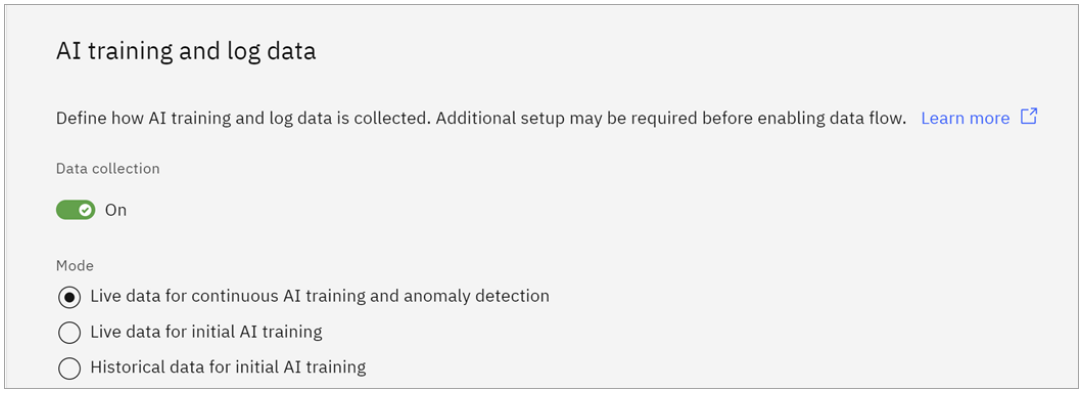

Figure. AI training

Important: Keep in mind the following considerations when you select your data collection type:

- Anomaly detection for your integration occurs if you select *Live data for continuous AI training and anomaly detection*.
- Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.

2. Click **Next**.
3. On the *Resource requirements* page, you can review the slot usage for your log integrations to see if there are enough slots to fully support the integration for multizone high availability.

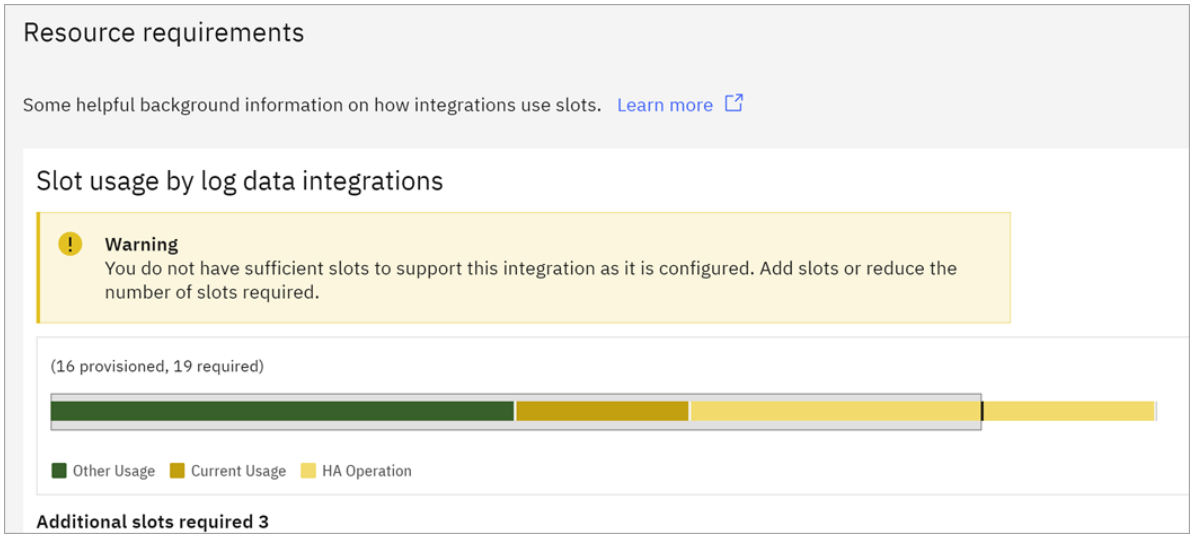

Figure. Resource requirements

If you set the **Data collection** toggle to **On**, you will see the resource management overview.

- If your current usage and other usage are less than the provisioned slots, but the HA slots exceed the provisioned slots, you will be able to create the integration, but will see a warning that you do not have enough slots. The integration will not have multizone high availability.
- If your projected usage exceeds the provisioned slots, you will not be able to create the integration because you do not have enough slots on your system for log data integrations.
- If your total slots, including HA slots, are within the provisioned slots, the integration will have multizone high availability.

  Note: HA operation assumes high availability for three zones.

If you set the **Data collection** toggle to **Off**, you will see a message stating that you need to enable logs data collection to see the resource management overview. When data collection is off, no slots are used by that integration.

4. Click **Save**.

You have created a Mezmo integration in your instance. After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling Mezmo integrations.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Enabling and disabling Mezmo integrations

If you did not enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Mezmo** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section. Set **Data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting Mezmo integrations.

Editing Mezmo integrations

After you create your integration, your can edit the integration. For example, if you specified *Historical data for initial AI training* but now want your integration to pull in live data for continuous monitoring, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Mezmo** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Mezmo integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Mezmo integrations. For more information about deleting a integration, see Deleting Mezmo integrations.

Deleting Mezmo integrations

If you no longer need your Mezmo integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before you delete your integration. For more information about disabling data collection, see Enabling and disabling Mezmo integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Mezmo** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Mezmo integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Note: If you manually send Mezmo logs from an archive, the model performs as expected only on other logs that are sent from the archive. Mixing archived data and data from the active service instance results in lower quality models.

Creating New Relic integrations

A New Relic integration collects live and historical metric data from the New Relic server in IBM Cloud Pak® for AIOps. This metric data helps to monitor and analyze application performance. To activate the integration, you must have an endpoint and an Access Token ready. The metric anomaly detection AI algorithm is used to analyze the New Relic metrics for identifying deviations from the normal behavior and detecting anomalies. New Relic v6.5.2 with v2 API is the version that is supported for the New Relic integration.

For more information about working with New Relic integrations, see the following sections:

- Creating New Relic integrations
- Enabling and disabling New Relic integrations
- Editing New Relic integrations
- Deleting New Relic integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating New Relic integrations

To create a New Relic integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **New Relic** tile.

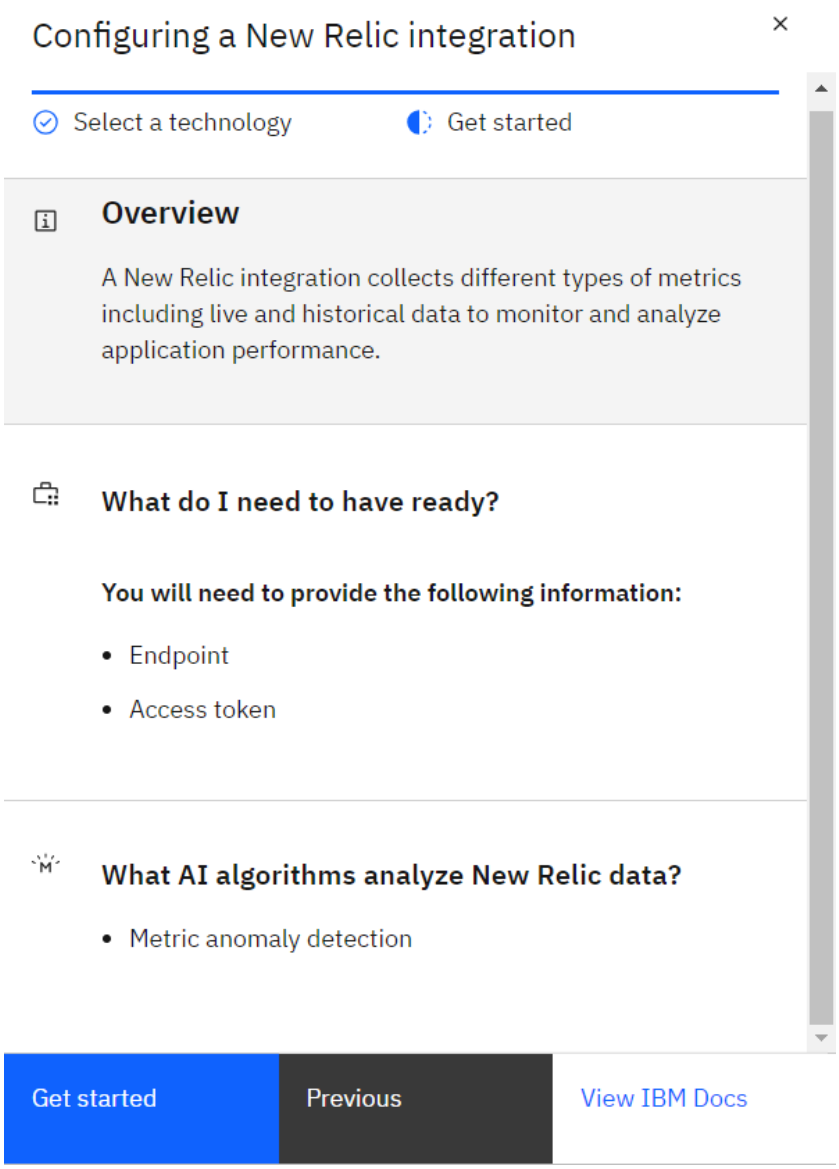
   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section, or alternatively start typing the integration name in the search bar and the corresponding tile will appear.
5. On the side-panel, review the instructions and select your required options from the following sections:
   - **Select the data types that you need to collect**: Select the relevant checkbox for *Metrics* or *Topology*.
   - **Specify whether you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visability to New Relic* radio buttons.
   - **Select Cloud Pak for AIOps integration**: You can leave this at the default *Use the integration that is recommended by Cloud Pak for AIOps*, or uncheck this and select either *Metrics* or *Topology*.

   Figure. Configure New Relic integration

   The below steps presuppose you select *Metrics* but if you do select *Topology* then you will be brought to a *New observer job* page. The New Relic observer only supports a load job. When a New Relic job is run, it will gather and read New Relic Infrastructure data from New Relic Insights using New Relic APIs. As a query job, it can be used to load baseline topology data and consequently synchronize it. For more information, see Configuring a New Relic observer job.
6. Then click **Next**.

   You see an overview, further direction such as *what you need to have ready* and also *what algorithms analyze New Relic data*.



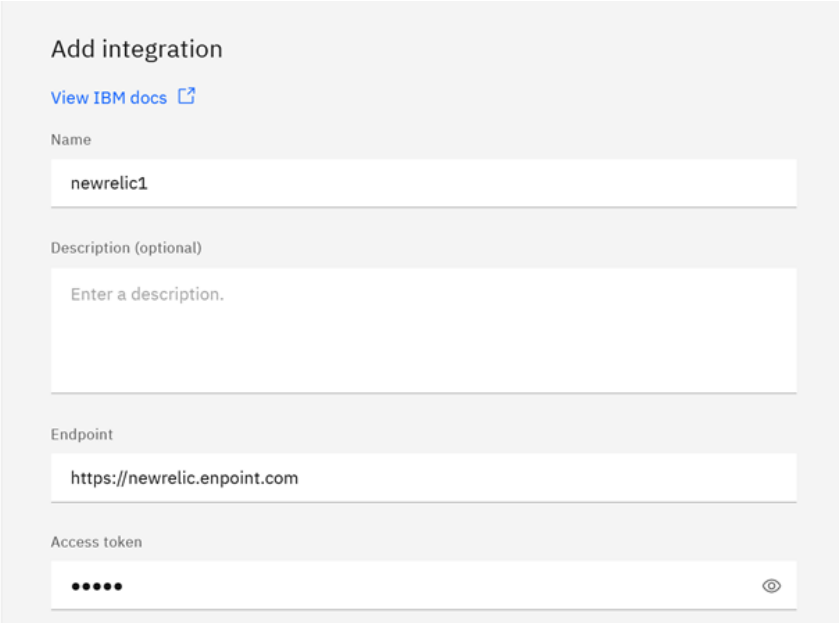


Figure. Configure New Relic integration - get started

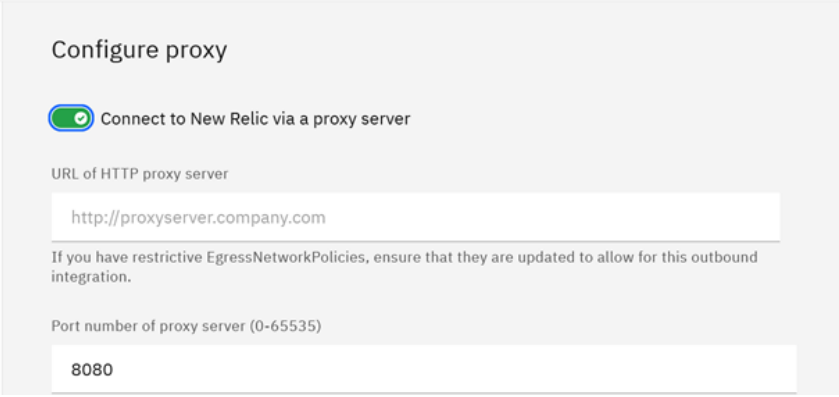
7. Click **Get Started**.
8. On the *Add integration* page, define the general integration details:
    - **Name**: Enter the display name of your integration.
    - **Description (optional)**: Type in a description for the integration.
    - **Endpoint**: Enter an endpoint for the integration. For example `https://api.newrelic.com`.
    - **Access token**: Enter an access token for the integration. You can create or obtain the access token from the *API Keys* section in your New Relic account.



- **Deployment options**: Select one of the options, **Local** or **Remote**. *Local* deploys the integration in the same cluster where IBM Cloud Pak for AIOps is installed. Alternatively, *Remote* deploys it in your chosen location.

Note: If you select *Remote*, after adding the integration, you are provided with a bootstrap command to finish the deployment.

Important: Podman must be installed to execute the remote deployment script with a recommended minimum version of 4.4.1. Read and write access are required for the folder where the remote deployment script will be executed and the script also must have execution permissions in order to be run. No more than one remote deployment script should be executed per host.

9. To verify the SSL/TLS configuration:
    1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
    2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.
10. Click **Test Connection**. If successful, a Test succeeded message is displayed.
11. Click **Next**.
12. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to New Relic via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server.
    - **Port number of proxy server**: Enter a port. The default is 8080.

Note: Only unauthenticated HTTP proxy is supported.

13. Click **Next**.
14. On the *Collect metric data* page enter your preferences to define how you want to collect metric data:
    - **Enable data collection**: Set *Enable data collection* to on. However, if you disable data collection, a new integration is created, but metrics are not collected.
    - **Select application**: Select one or more applications from the list to see their associated metrics in the filter table. The filter table displays all the associated metrics of the selected applications.

- **Search and select the required metrics from the filter table**: Search through all the metrics and select the metrics from the table. By default, all metrics are selected. To remove a selected metric, search to locate it and clear its corresponding checkbox. You can also click **Cancel** to remove all selected metrics or **Select all** to reselect them.
- **Aggregation interval (minutes)**: Enter a value in minutes. The value represents the time interval for live or historical data collection. The default value is 5 minutes.

  Note: If aggregation interval is less than 60 minutes, IBM Cloud Pak® for AIOps collects only a maximum of past 8 days of historical data. This is because the integration aggregates data in hourly periods, instead of the time you enter, when the data request time range is older than 8 days. For more information about aggregation interval, see the New Relic documentation.
- Select to collect *historical* or *live* data.

  Note: If you choose to collect only live data, you cannot collect historical data after the live data collection starts.
- **Live data collection**: To collect live data, complete the following steps:
  - **Only live data once the integration is established**: Select the checkbox.
  - **Scheduler run time (minutes)**: Enter a value in minutes. The value represents the frequency at which data is collected for live metrics. The default value is 5 minutes.
- **Historical data collection**: To collect historical data, complete the following steps:
  - **Start date and time**: Select the start date from the calendar and enter the time in the *hh:mm* format (hours and minutes).

    Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.
  - **Time zone**: Select your time zone from the dropdown list.
  - **End date and time**: Click **Add end date** and select a date from the calendar. Also, enter the time in the *hh:mm* format (hours and minutes). If you want to remove an end date, click **Remove end date**.

    Note: If you do not set an end date, IBM Cloud Pak for AIOps collects historical data from the specified start date and continues with live data collection. You cannot collect historical data after the live data collection starts.
  - **Scheduler run time (minutes)**: Enter a value in minutes. The value represents the frequency at which data is collected for live metrics. The default value is 5 minutes.

    Note: Scheduler run time is only applicable to live mode. You must configure the scheduler run time only if you do not add an end date as the integration will continue to run in live mode after historical mode.

15. Click **Done**.

For more information about performance considerations for metric data collection, see Performance considerations for metric data collection.

Enabling and disabling New Relic integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **New Relic** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect metric data* section. Set **Enable data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting an integration, see Deleting New Relic integrations.

Editing New Relic integrations

After you create your integration, you can edit it. To edit an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **New Relic** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the New Relic integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration as required. Click **Save** when you are done editing.

You edited your integration.

Deleting New Relic integrations

If you no longer need your New Relic integration and want to delete it entirely, you can delete the integration from the console.

To delete an integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **New Relic** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the New Relic integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating observer jobs

Observers for Instana and ServiceNow are configured as part of the standard integration process on the Integrations page in the UI. These observers can collect data from different types of data sources. Additionally, other topology observers are accessible on the Integrations page in the UI, and link to the Topology Manager UI. To run other observer jobs, you can configure and schedule the jobs through the Topology Manager UI.

Observers provide topology data for integrations, which can help with understanding how resources are connected to each other. In addition, they provide probable cause information for events that are published to integrated collaboration tools like Slack and Microsoft Teams.

For more information about working with observer jobs, see Defining observer jobs.

Creating PagerDuty integrations

A PagerDuty integration provides event data that is analyzed and processed into alerts. An incident is generated, based on an alert severity, and published to your incident viewer interface with insights into potential issues that impact operations.

Contextual alerts can be grouped into an incident by using temporal, topological, and scope correlation methods. For more information, see About events, alerts, and incidents.

The source attribute in the event is used to get the entity information. The entity information is used for the application resolution and the event grouping. For more information, see Application incidents, and Managing incidents and alerts.

For more information about working with PagerDuty integrations, see the following sections:

- Creating PagerDuty integrations
- Enabling PagerDuty integrations
- Editing PagerDuty integrations
- Deleting PagerDuty integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating PagerDuty integrations

To create a PagerDuty integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **PagerDuty** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.

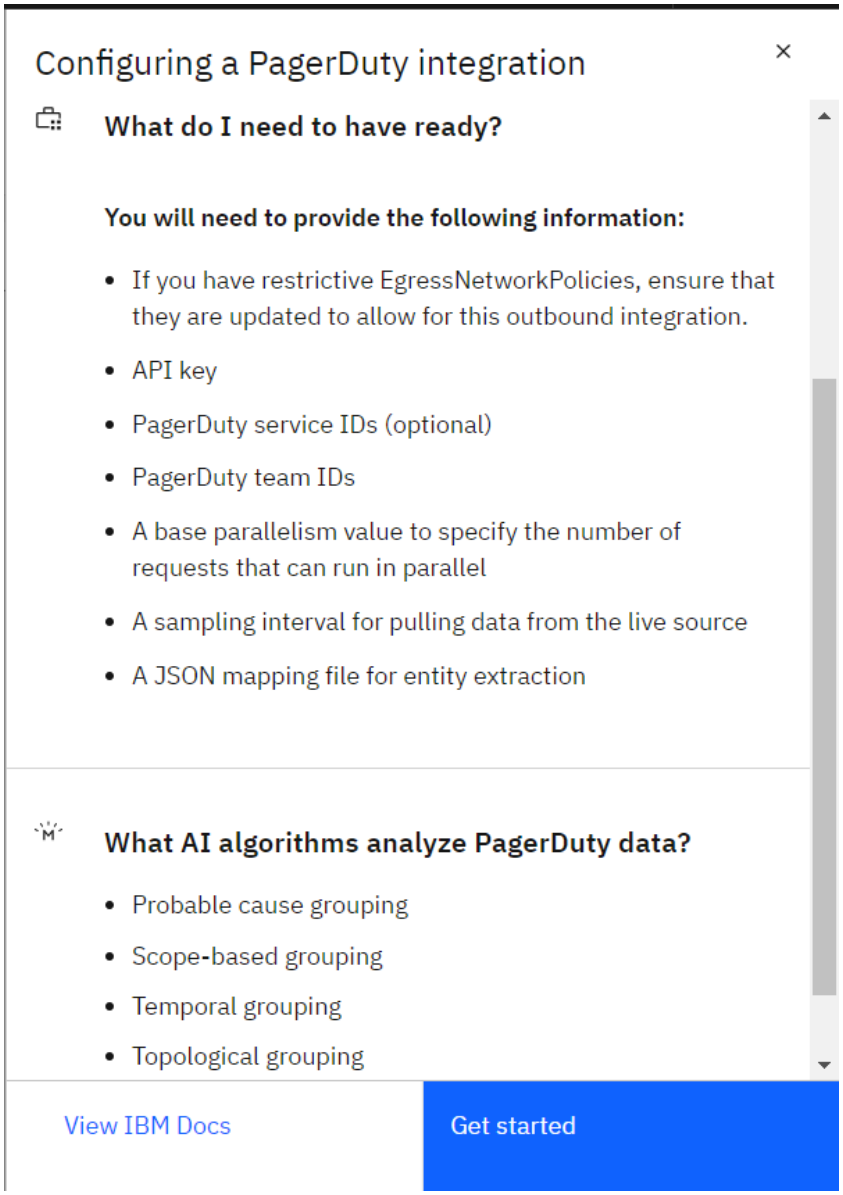


Figure. Configure Pagerduty integration

6. On the *Add integration* page, define the general integration details:

   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **API key**: The integration token for your PagerDuty instance.
   - **Service IDs**: An optional comma-separated list of PagerDuty service IDs. The service ID can be obtained from the PagerDuty URL. If you view a specific service, the PagerDuty URL might be something like the following URL: https://xyz.pagerduty.com/service-directory/P4FY6G2 For this example, the service ID could be `P4FY6G2`.

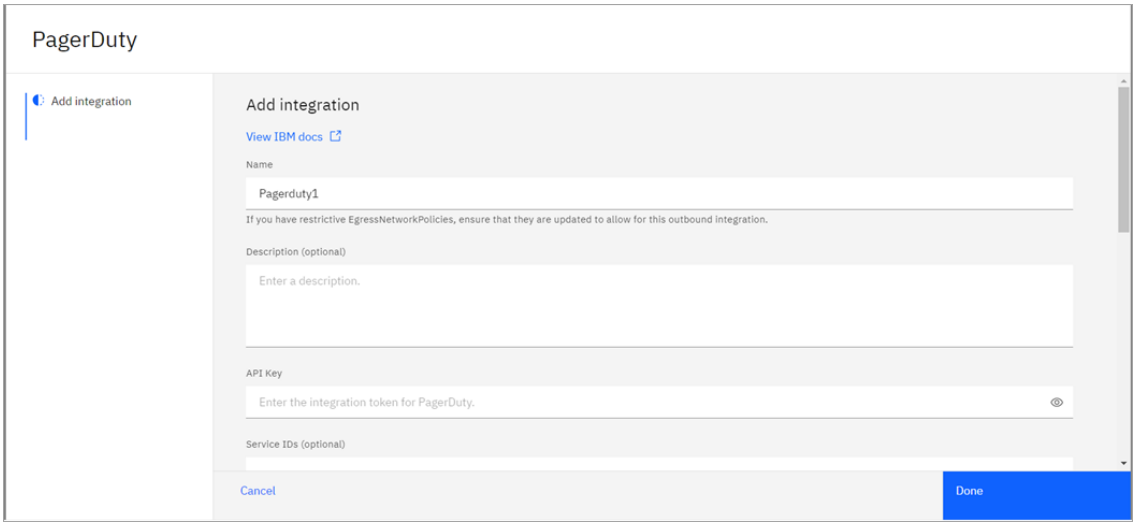

Figure. Create Pagerduty integration

- **Team IDs**: An optional comma-separated list of PagerDuty team IDs. If you view a specific team, the PagerDuty URL might be something like the following URL: https://ibm.pagerduty.com/teams/PV429MG In this example, the team ID is `PV429MG`.
- **Base parallelism**: It is recommended to use a higher value than 1 so that you can process data in parallel. In a small environment the available flinks slots is 16 and for a large environment, the maximum available slots is 32.
- **Sampling rate**: The rate at which data is pulled from live source (in seconds). The default value is `60`.
- **Data flow**: Set the toggle to 'On' to enable event data from PagerDuty to flow to IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling PagerDuty integrations.

  Note: When the `body.cef\_details` attribute is not present in the raw data from PagerDuty, there is no way to extract the entity and assign it to the `resource` attribute in the event input and the event cannot be associated with an application.

You can test your integration by clicking **Test connection**.

Note: PagerDuty mappings are the default mappings for IBM Cloud Pak for AIOps's standard fields for events.

7. Click **Done**.

You created a PagerDuty integration in your instance.

```
![Pagerduty integration](../images/int_pagerduty_running.png){: caption="Figure. Pagerduty integration running" caption-side="bottom"}
```

To create more integrations, see Configuring Integrations.

For more information about working with the insights provided by your integrations, see Managing incidents and alerts.

Enabling and disabling PagerDuty integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **PagerDuty** integration type.
4. Click the integration that you want to enable or disable.
5. Set **Data collection** to **On** or **Off** to enable or disable log data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting PagerDuty integrations.

Editing PagerDuty integrations

After you create your integration, your can edit the integration. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **PagerDuty** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the PagerDuty integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.

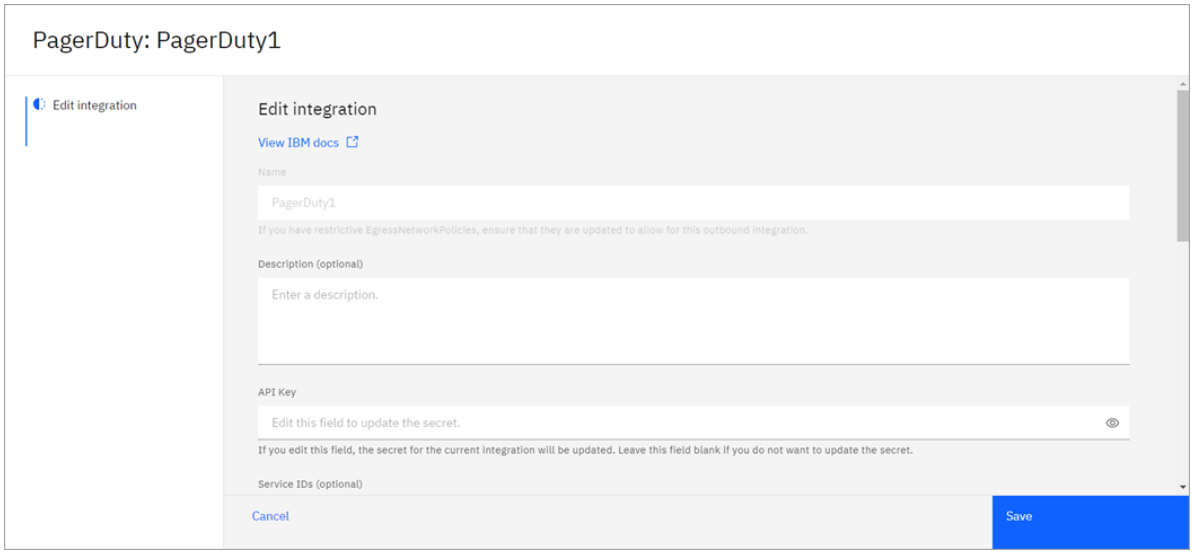

Figure. Edit Pagerduty integration

5. Edit your integration. Click **Next** to go through the integration configurationn pages. Click **Save** when you are done editing.

You edited your integration. If you did not previously enabled or disabled your application, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling PagerDuty integrations. For more information about deleting a integration, see Deleting PagerDuty integrations.

Deleting PagerDuty integrations

If you no longer need your PagerDuty integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable data collection before you delete your integration. For more information about disabling data collection, see Enabling and disabling PagerDuty integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **PagerDuty** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the PagerDuty integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating a ServiceNow integration

A ServiceNow integration allows users to send Cloud Pak for AIOps incidents and alerts to ServiceNow. Optionally, historical and live ServiceNow data can be collected by Cloud Pak for AIOps for more advanced capabilities such as: change request assessments, similar ticket functionality, topology, and bi-directional updates to Cloud Pak for AIOps incidents and alerts.

The ServiceNow integration triggers the following alerts:

- Instance is hibernating
- ServiceNow credentials unauthorized
- Instance does not exist or is deleted
- IBM Cloud Pak for AIOps ServiceNow integration is not installed on ServiceNow

For more information about alerts, see About events, alerts, and incidents.

About this task

Similar incidents, such as from a ServiceNow integration, are called similar tickets. Similar tickets are grouped with other tickets from other integrations as input to IBM Cloud Pak for AIOps AI algorithms.

If your connected ServiceNow application is version 4.4.0 or later, IBM Cloud Pak® for AIOps incidents and alerts are kept up to date in ServiceNow. Specifically the following fields:

- incidents: short description, description, priority, and state
- alerts: alert summary, state, severity, event count, and last occurrence

Prerequisites

- Before you create a ServiceNow integration, you must create users and configure ServiceNow. For more information about configuring ServiceNow, see Configuring the ServiceNow App for IBM Cloud Pak for AIOps.
- Your ServiceNow application must be version 4.4 to connect with IBM Cloud Pak® for AIOps version 4.8.0. This integration is not supported for earlier versions of the ServiceNow application.
- ServiceNow instances with self-signed certificates are not supported for connecting with IBM Cloud Pak for AIOps.
- You can have only one ServiceNow integration per instance.

For more information about working with a ServiceNow integration, see the following sections:

- Creating a ServiceNow integration
- Enabling a ServiceNow integration
- Editing a ServiceNow integration
- Deleting a ServiceNow integration
- Troubleshooting a ServiceNow integration
- Known issue with a ServiceNow integration

Creating a ServiceNow integration

To create a ServiceNow integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **ServiceNow** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section.
5. On the side-panel, review the instructions and when ready to continue, click **Get started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: The display name of your integration.
   - **Description**: An optional description for the integration.
   - **URL**: The URL of your ServiceNow instance. For example `https://myinstance.service-now.com`.

     Important: If you have any restrictive EgressNetworkPolicies in place, ensure that they are updated to allow for this outbound integration. For more information, see Postinstallation tasks.
   - **User ID**: A ServiceNow user with say a `ibm.aiops` user ID and an `x_ibm_waiops.admin` role.

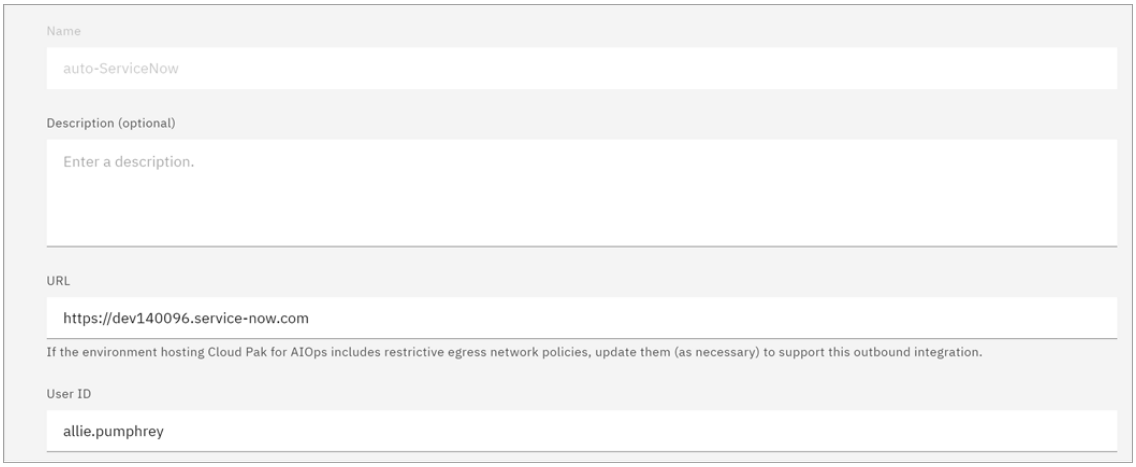

Figure. Enable Service Now integration

   Important: You must create a new, unique user in ServiceNow specifically for your ServiceNow integration before you create your integration. Make sure that you are using the correct user role, the *x_ibm_waiops.admin*, for your integration. You must also make sure that the time zone set for this user matches your system time zone in ServiceNow. For more information about ServiceNow users, see Managing roles.
   - **Password**: Your ServiceNow password for `ibm.aiops` user.
   - Select the orchestration or deployment type as **Local** or **Remote**.

     Note: If you select 'Remote' you will be provided with a bootstrap command to finish the orchestration.

Click **Test Connection** to validate the ServiceNow instance and credentials. If the test fails, verify the ServiceNow instance is stable and that the credentials are correct.

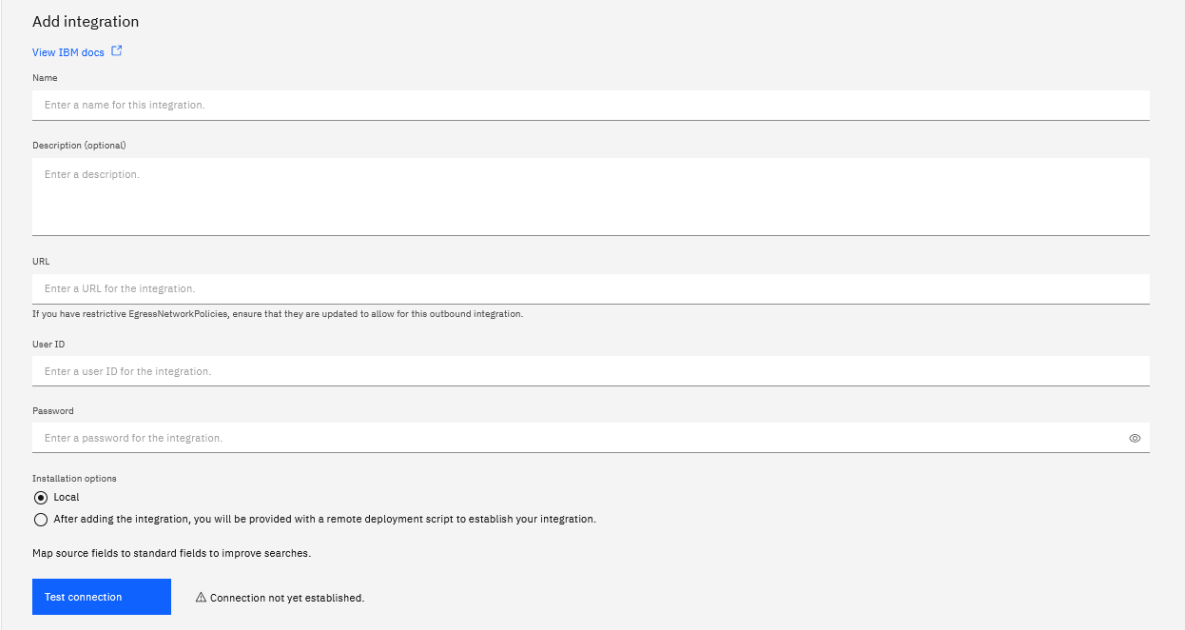

Figure. Test connection button

7. Click **Next**.
8. (Optional) Enter *Field mapping* information.

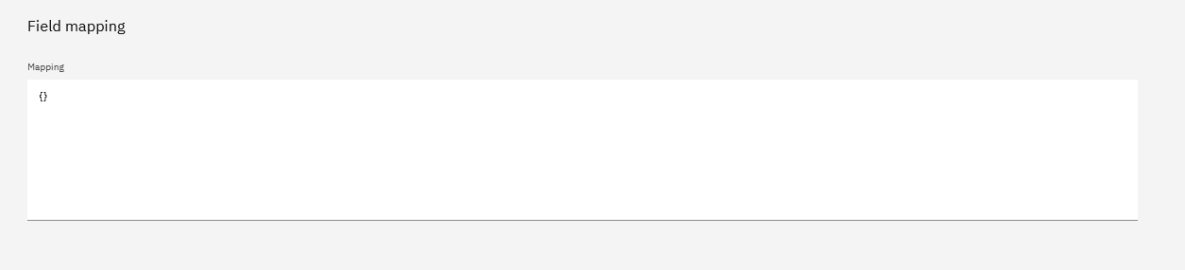

Figure. Field mapping setting

With this field, you can map custom data fields to default fields in ServiceNow. The **change_request** and **incident** tables are queried from ServiceNow. These fields are used for AI training. These tables can be modified to include additional columns.

- The following **change_request** fields are extracted:

  ```
  "u_environment", "u_environment_id", "cmdb_ci", "short_description", "u_purpose", "description",
  "backout_plan", "close_notes", "state", "close_category", "sys_created_by", "assigned_to", "sys_domain",
  "category", "business_service", "priority", "approval", "type", "contact_type", "production_system", "impact",
  "reason", "justification", "start_date", "end_date", "work_start", "work_end", "calendar_duration",
  "close_code","delivery_task", "implementation_plan", "test_plan", "work_notes_list"
  ```

- The following **incident** fields are extracted:

  ```
  "short_description", "description", "u_caused_by_change", "caused_by", "close_code", "u_detection_source",
  "close_notes", "u_environment","cmdb_ci", "comments_and_work_notes", "impact", "problem_id", "priority",
  "severity", "state", "resolved_at", "closed_at", "opened_at", "parent", "made_sla", "watch_list",
  "upon_reject","sys_updated_on", "child_incidents", "hold_reason", "approval_history", "resolved_by",
  "sys_updated_by","opened_by", "user_input", "sys_created_on", "sys_domain", "sys_created_by", "knowledge",
  "order","calendar_stc", "delivery_plan", "contract", "active", "business_service", "sys_domain_path",
  "rfc","time_worked", "expected_start", "business_duration", "group_list", "work_end", "caller_id",
  "reopened_time", "approval_set", "subcategory", "correlation_display", "delivery_task", "work_start",
  "assignment_group", "additional_assignee_list", "business_stc", "calendar_duration", "notify",
  "service_offering", "sys_class_name", "closed_by", "follow_up", "parent_incident", "contact_type",
  "reopened_by", "incident_state", "urgency", "company", "reassignment_count", "activity_due", "assigned_to",
  "comments", "approval", "sla_due", "due_date", "sys_mod_count", "reopen_count", "sys_tags", "escalation",
  "upon_approval", "correlation_id", "location", "category", "work_notes_list"
  ```

Example: If you add a custom column (named **my_custom_field1_name**) into the table, the prefix **u_** is added so the field must be queried as **u_my_custom_field1_name**. If this field contains useful description information for training, you might want the existing **description** field to be updated for both change requests and incidents to use this data. To support this mapping, you need to add the following JSON to the *Field mapping*:

```
{
  "codec": "servicenow",
  "description": "u_my_custom_field1_name"
}
```

With this mapping, the **description** value is replaced with the value from **u_my_custom_field1_name**. For example, assume the default **description** field has the value **Server down for 2 hours due to an upgrade** and the **u_my_custom_field1_name** field had the value **Impact: server down, Duration: 2 hours, Cause: server upgrade**. With the above mapping in place, the **description** now has the value **Impact: server down, Duration: 2 hours, Cause: server upgrade**. This **description** value is also now used for AI training. If the mapping is not in place, the **u_my_custom_field1_name** value is not used for AI training as it is not examined through the integration.

Adding the field mapping can give you flexibility to add your own custom fields into AI training. Also, if an existing field should not be used for training, you can add a new custom column with a default value to use for training instead of the existing field value.

Notes:

- The field mapping is applied to both historic and live data. Once the mapping is set in the integration and training is completed, the mapping should not be changed. Otherwise, if new change requests or incidents are queried, the mapping is not applied properly, which can cause results to be less accurate.
- Currently, the field mapping applies to all tables. If a custom field does not exist in a table, a workaround is to create that custom field with default values to ensure that the mapping does not fail. Otherwise, the data is not be retrieved properly for that table.

9. Click **Next**.
10. (Optional) Select whether to *Collect topology data*, and if selected, set the options for data collection:
    - **Collect inventory and topology data**: Set to **On** for inventory and topology data collection. You can also set advanced options.
    - **Schedule request**: Set to **On** and this allows you set the **Job Schedule** (optional)
        - **Start date**: The start date of when the job is to run.
        - **Time**: The time to run the observer job.
        - **Time interval (period)**: How frequently to run the job (either by hour, minute, days, or weeks).
        - **Interval**: The duration of time between runs based on the *Time interval (period)*. For example, if you wanted the job to run every 2 hours, set the interval to **2** and the *Time interval (period)* to *hours*. Enter **0** for the *Interval* to run the observer job one time (and manually through the interface otherwise).
    - Set advanced options section:
        - **Number of records to fetch per API calls from a table**: The number of records to fetch per API calls from a table. Default value is **10000**. The value should be between **100** and **10000**.
        - **Entity mapping for the sysClassNames parameter to overwrite the entity type**: To use a user-defined entity type, enter a parameter to overwrite the default **sys_class_name**. Separate the values of the class name and the new entity type name with a colon. For example, **cmdb_ci_linux_server:node**.
        - **ServiceNow tables to be discovered by observer**: The supported tables to be discovered are **sys_user** and tables that are either system or user created children of **cmdb_ci**.
        - **Trust all certificates by bypassing certificate verification**: If **On**, the observer allows the integration to the target environment without verification. The default value is *On*.
            - **Options to exclude entity edges**: Select an exclude option to exclude resource edges. You can select the following options. The default value is **none**.
                - **none**
                - **uniqueID**
                - **entityType**
            - **List of entities to exclude edge modelling**: The listed entities will be not have any edge connectivity to any entities.
            - **Use an 'include' or 'exclude' filter in API requests**: Specify that the API filter should use include or exclude in every ServiceNow API call. Enter the filter attributes in the **filter_resources** parameter.
            - **Filter resources based on defined JSON attributes**: To use a filter in API calls to retrieve resources, enter the JSON **key:value** attribute. Use the format **key=value** where value can be more than one, for example **key=value1,value2,value3**. For more than one key, use **|** as a delimiter, for example, **key=value1|key=value1,value2,value3**.
            - **Number of connection retries**: Set the number of times a connection should try again. The default value is **2**.
            - **Delay before a connection retry (milliseconds)**: Specify the period of time in milliseconds to delay before a connection tries again.
            - **Maximum number of tables per cmdb_ci_rel api batch call**: Specify this configurable parameter to split one long call into multiple small calls. This prevents the cmdb_ci_rel (relationship) query from being too long. The default and maximum value is **10**.
            - **Integration timeout**: The amount of time before a connection times out in milliseconds. The default value is **5000** milliseconds.
            - **Read timeout**: The amount of time before a read operation times out in milliseconds. The default value is **5000** milliseconds.
            - **Proxy Host**: The proxy on the network that AIOps is deployed on for making external requests to any target.
            - **Proxy Port**: The proxy port on the network that AIOps is deployed on. The default value is **8080**.
            - **Proxy Username**: Specify the username for connecting to the proxy.
            - **Proxy Password**: Specify the password for connecting to the proxy.

- **Proxy Secure**: Specify whether the proxy server is secure. The default value is `false`
- **Access Scope**: An optional CSV String that lists the values which can be used to provide a scope for the resources. These values can be used to aid the mapping of alerts to resources when resources that are in different scopes share the same matchTokens. Examples of scope can be locations, project names, or namespaces.
- **Generate debug support file**: Set to **On** to generate the debug support file. The default is **Off**.

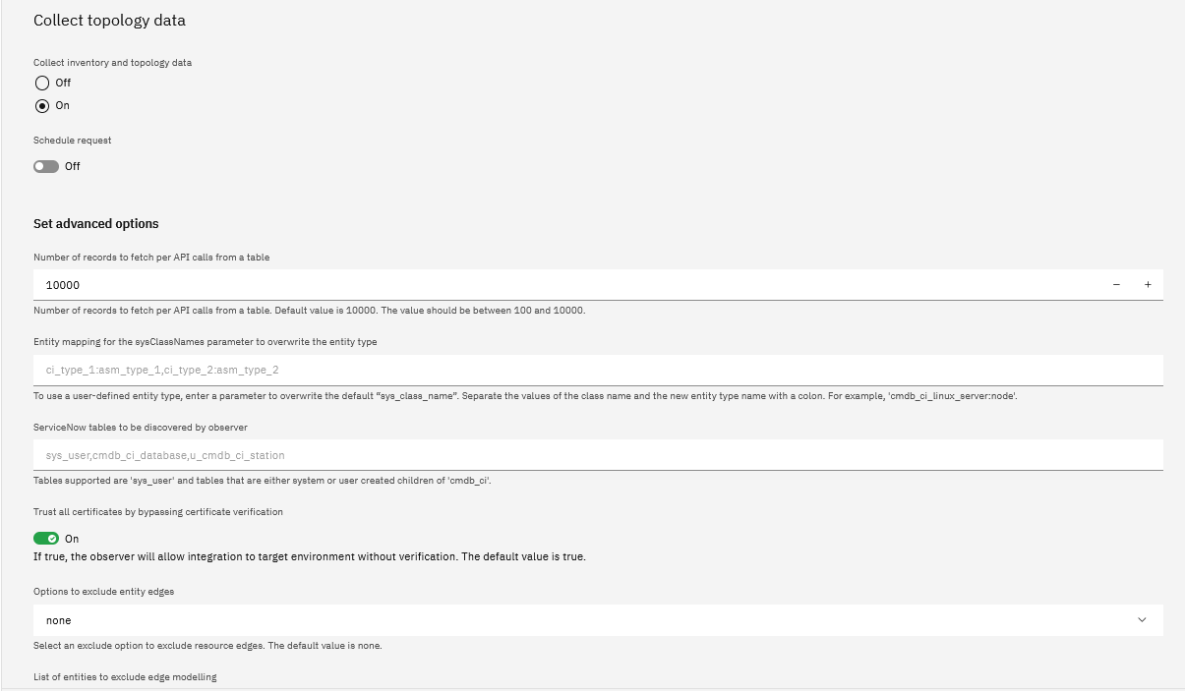

Figure. Topology data collection settings

For information about REST APIs and ServiceNow, see Configuring ServiceNow Observer jobs and Topology REST Observer APIs.

11. Click **Next**.
12. On the *Configure tickets proxy and custom certificate* (optional) page complete the following fields:

    To verify the SSL/TLS configuration:

    1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
    2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.

    To connect to ServiceNow via a proxy server:

    1. Set the **Connect to ServiceNow via a proxy server** toggle button to *on*.
    2. Enter a URL for the HTTP proxy server in the **URL of HTTP proxy server** field.
    3. Enter a port number for the proxy server in the **Port number of proxy server** field. The default is 8080.

    Note: Only unauthenticated HTTP proxy is supported.

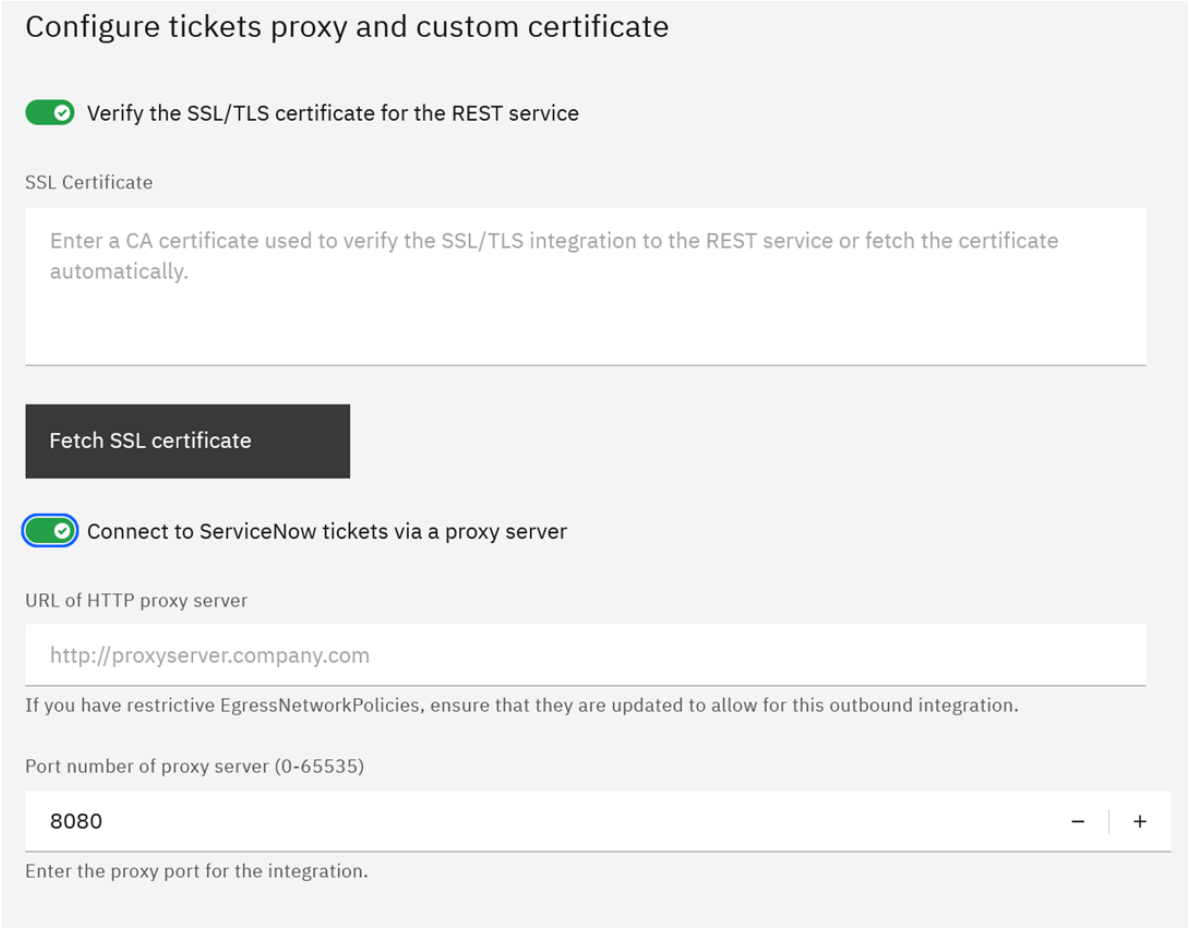

Figure. Configure proxy and custom certificate

13. Click **Next**.
14. (Optional) Enter the *Collect and synchronize operations data* information.

- **Live data - Train and use Change risk and Similar tickets algorithms; synchronize alert and incident data**

  Select the Live data collection mode to enable the following capabilities:

  - Provide risk assessments on change requests (after model is trained and deployed).
  - Update alerts in Cloud Pak for AIOps when corresponding incident-based alerts are updated in ServiceNow.
  - Update incidents in Cloud Pak for AIOps when corresponding incidents are updated in ServiceNow.
  - Collect resolved ServiceNow incidents for Similar tickets training. This option is required for similar tickets functionality.

  Note: If you are interested in utilizing change risk or similar tickets AI algorithms, you must first set **Mode** to **Historical data for ticket data collection** to collect a minimum amount of data, and then run AI training on that data. For more information, see Planning data loading and training.

  - **Configuring polling intervals for live data collection**: Live data collection is done at configurable intervals ranging anywhere from every 10 seconds to once a day. For risk assessments and similar tickets polling, the default is 15 minutes. For alert and incident polling, the default is 1 minute. The default values serve as a starting point but polling can be done at longer or shorter intervals depending on user preference.

    Important: Updates made to Cloud Pak for AIOps data (incidents and alerts) in ServiceNow by the integration user (ibm.aiops) will not be synchronized in Cloud Pak for AIOps. A different ServiceNow user must be used when making updates to Cloud Pak for AIOps data in ServiceNow.

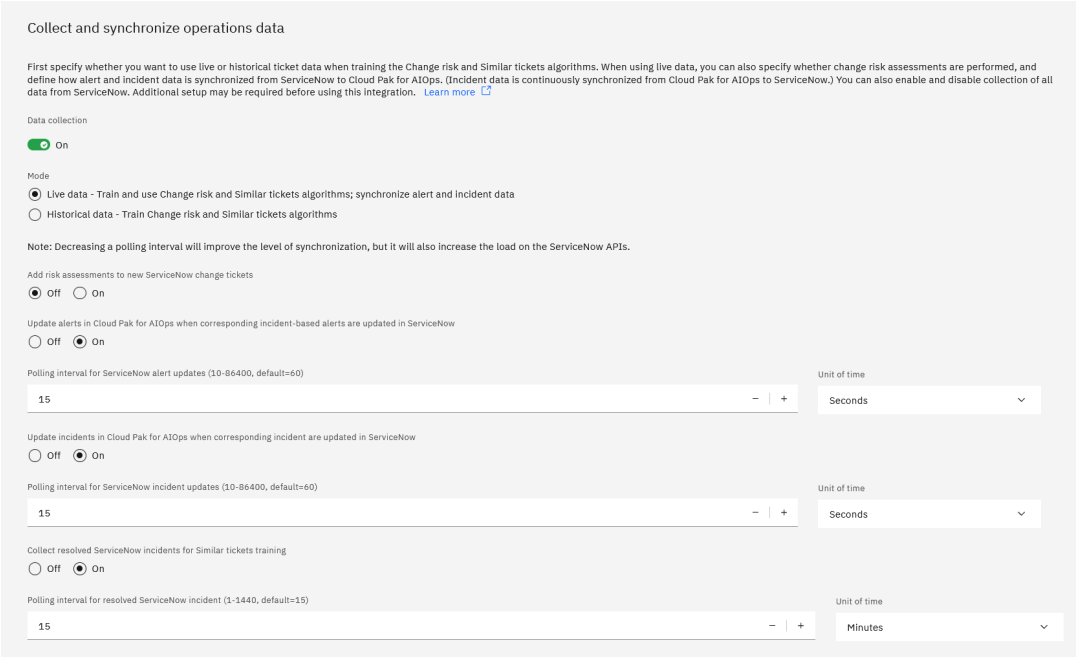

Figure. Live data

- **Historical data - Train Change risk and Similar tickets algorithms**

  To enable the change risk and similar ticket algorithms, a single set of training data is necessary to train the AI model. You complete the 'Start' and 'End' date fields.

  - **Ticket types**: Specify the types of ServiceNow tickets that you want to pull in to the system. By default, change request and incident tickets are included and data is queried from those ServiceNow tables. You can edit this list to remove any types you don't want to sample.

    Important: Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.

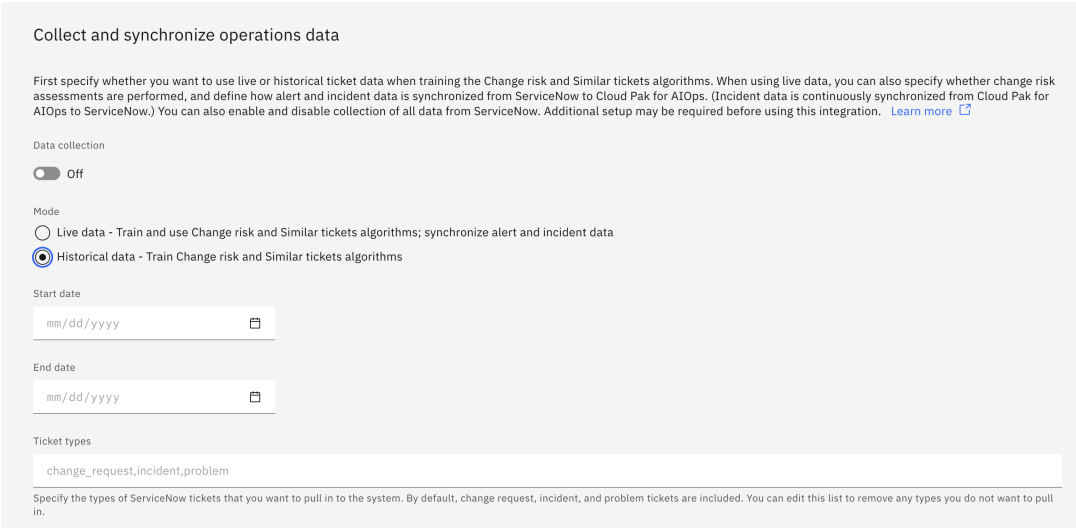

Figure. Historical data

15. Click **Done**. You have created a *ServiceNow* integration in your instance
16. To use the integration that you created, configure it in a policy. For more information, see Configure a policy.

After the integration creation is complete, and if you selected the *Remote* option for integration deployment, you can download the *bootstrap script* by selecting the created integration, and clicking **download** from the options menu (three vertical dots). If a script is regenerated, it invalidates the credentials of previously downloaded scripts for that integration.

Note: You can either copy the script or download as an sh file to run it on a remote cluster.

Prerequisites before running the bootstrap script on remote cluster:

- Podman needs to be installed on the remote cluster.
- Log in to the *Image registry* for the script to pull in the image that uses the Podman login command.

After you create your integration, you must enable the data collection to connect your integration with the AI of IBM Cloud Pak for AIOps. For more information about enabling your integration, see Enabling a ServiceNow integration. To verify that your job completed successfully, view the schedule status of your

ServiceNow integration in the *Schedule integrations* tab.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management. For more information about change risk from ServiceNow, see Change risk.

Training a Change Risk model

For more information about training a change risk model, see Training a Change Risk model.

Enabling and disabling a ServiceNow integration

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **ServiceNow** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *Collect ticket data* section. Set **Data collection** to **On** or **Off** to enable or disable data collection. Disabling data collection for an integration does not delete the integration.

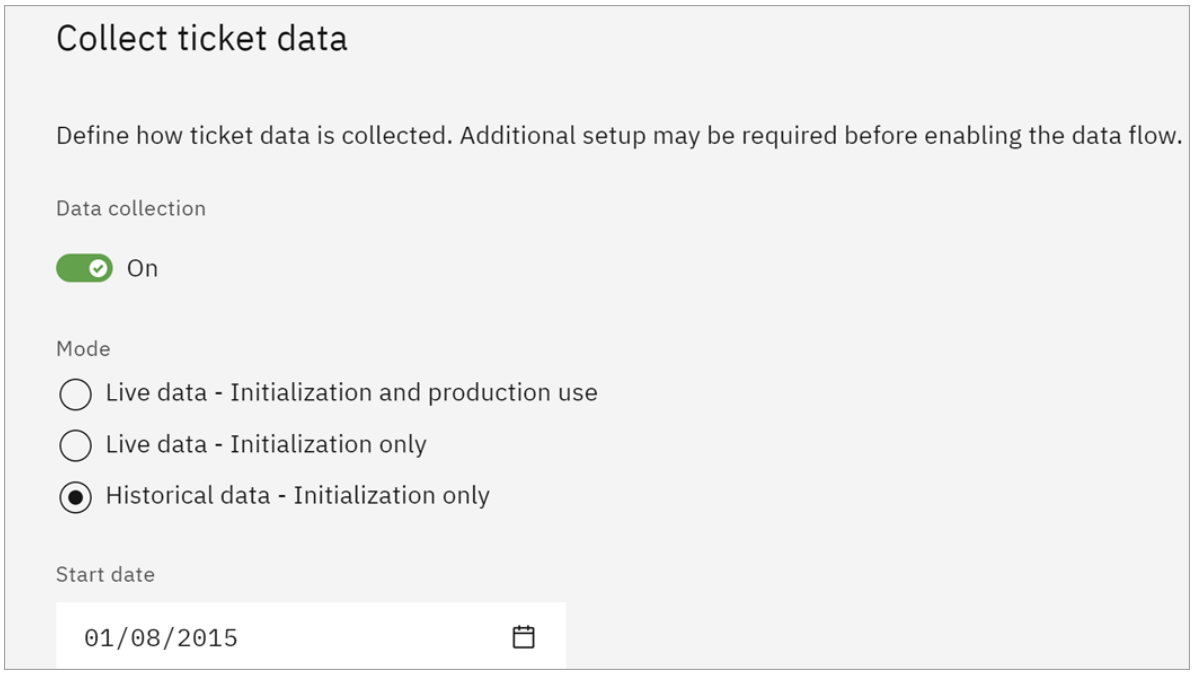

Figure. Enable Service Now integration

You enabled or disabled your integration. For more information about deleting a integration, see Deleting a ServiceNow integration.

Editing a ServiceNow integration

After you create your integration, your can edit the integration. For example, if you specified *Historical data for initial AI training* but you now want your integration to sample live data for continuous monitoring, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **ServiceNow** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the ServiceNow integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration. Click **Next** to go through the integration configurationn pages. Click **Save** when you are done editing.

You edited your integration. If you did not enable ticket data collection when creating your integration, you can enable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling a ServiceNow integration. For more information about deleting a integration, see Deleting a ServiceNow integration.

Note: After you upgrade, you might find that the **Next run** field in the **Scheduled integrations** tab is showing the last run time of the scheduled job, instead of the next run time. If this happens, the next run time should be regarded as the last run time.

Deleting a ServiceNow integration

If you no longer need your ServiceNow integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable ticket data collection before you delete your ServiceNow integration. For more information about disabling ticket data collection, see Enabling and disabling a ServiceNow integration.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **ServiceNow** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the ServiceNow integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Note: Alerts that are generated from the ServiceNow integration are automatically cleared when the integration is deleted.

Mapping similar ticket data from ServiceNow

If you need to use historical incidents from ServiceNow as similar ticket data, you need to map the data to an expected format and insert the data into Elasticsearch.

Historical incidents are required to first be inserted into Elasticsearch for similar ticket data. The data format consists of one incident record per line, in JSON format, with the original raw data. Raw data must be normalized to the IBM Cloud Pak for AIOps target format. This normalization includes mapping fields, converting date-time formatting, and more. Incidents are then inserted in batch. When the insertion is done, IBM Cloud Pak for AIOps tries a simple search to make sure everything runs as expected.

For more information about training similar tickets models in IBM Cloud Pak for AIOps, see Setting up training for similar tickets.

Raw similar ticket data

IBM Cloud Pak for AIOps ingests incidents from standard or custom data sources, for the incidents to be analyzed for similarities and action recommendations. Offline historical raw incidents are first uploaded to the Elastic database to extract indexes and set the stage for finding incidents that are similar to incoming live incident data.

You do not need to transform raw incident data into a normalized format. For more information about normalization, see Normalized output data schema.

Normalization is automatically done in similar incidents model training step. For example, the following raw JSON incident data comes from ServiceNow:

```
{
    "source": "https://dev82395.service-now.com/incident.do?sysparm_query=number=INC0010062",
    "number": "INC0010066",
    "short_description": "Containers being killed in ts-payment-mongo service. Users may notice issues during payment",
    "description": "",
    "opened_at": "2020-01-08T22:48:23Z",
    "sys_created_on": "2020-01-08T22:48:23Z",
    "sys_updated_on": "2020-01-08T22:48:23Z",
    "resolved_at": "2019-12-11T07:36:00Z",
    "closed_at": "2019-12-11T07:36:00Z",
    "business_duration": "",
    "severity": 3,
    "priority": 5,
    "impact": 3,
    "state": "closed",
    "comments_and_work_notes": "",
    "close_notes": "This issue has been resolved by the DBA team, which SQL queries were updated to reboot proxy agent to
prevent the monitoring notification system from failing.",
    "parent_incident": ""
}
```

In this example, you can extract data from ServiceNow. The source and format of your exported data doesn't matter.

For more information about exporting data from ServiceNow, see Exporting data.

For more information about managing incident data in ServiceNow, see Incident management.

Normalized similar ticket data

The following sample illustrates the result of mapping data from an external source for use with IBM Cloud Pak for AIOps:

```
{
  "application_group_id": "1",
  "application_id": "1",
  "timestamp": 1570221600,
  "utc_timestamp": "2019-10-04T20:40:00.038Z",
  "type": "incident",
  "incident": {
    "incident_id": "fed6b7bf-f741-49d1-ab36-5d04e9a5c128",
    "title": "Users are not able to access Discovery and Conversation in EU",
    "description": "Unable to connect to email using my laptop.",
    "created_at": "2019-09-11T06:39:48.000Z",
    "updated_at": "2019-09-11T07:57:58.000Z",
    "resolved_at": "2019-09-11T07:57:58.000Z",
    "closed_at": "2019-09-11T07:57:58.000Z",
    "started_at": "2019-09-11T07:57:58.000Z",
    "business_duration_ms": 15347,

}
```

Description of similar ticket normalized attributes

Required attributes expected as input to the pipeline

Attribute	Description
`title`	Short description or title of the incident.
`description`	Long description of the incident.
`timestamp/utc_timestamp`	Epoch timestamp of the event in the log entry and the `utc_timestamp` formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`created_at`	Coordinated Universal Time at which the incident was created formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`updated_at`	Coordinated Universal Time at which the incident was last updated formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`resolved_at`	Coordinated Universal Time at which the incident was resolved formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`closed_at`	Coordinated Universal Time at which the incident was closed formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`started_at`	Coordinated Universal Time at which the incident started formatted as `yyyy-mm-ddTHH:MM:SSZ`.
`severity`	Severity of the issue (integer)
`priority`	Priority of the issue (integer)
`impact`	Impact of the issue (integer).
`source_name`	Data source in which the incident is stored (for example, ServiceNow).
`source_url`	URL of the incident in the source.
`source_incident_id`	`incident_id` from the source (for example, `NUMBER` in ServiceNow).
`source_application_id`	Application from which the incident came (for example, the configuration item in ServiceNow).
`comments`	Comments or closed notes that talk about the list of actions that are taken, or comments that are added by the user who is attending to the incident.
`related_incidents`	Any related incidents, such as parent incidents, child incidents, or CIE documentation that is attached with the incident.
`resolution`	Any RCA ID or resolution that is provided for the incident.

Optional attributes that might add value

Attribute	Description
`business_duration`	Duration for which the incident was alive without resolution.

Static attributes

Attribute	Description
`application_group_id`	The `application_group_id` to support multitenancy. This value is provided as part of the initial configuration.
`application_id`	Application that IBM Cloud Pak for AIOps is monitoring. This value is provided as part of the initial configuration.

Attribute	Description
`type`	This value is hardcoded to the incident.
`timestamp`	Epoch time of the incident normalization, in seconds.
`utc_timestamp`	Normalization time in the Coordinated Universal Time time zone.
`incident_id`	The unique UUID.
`state`	Current state of the incident.

Attributes analyzed and populated in the pipeline

Attribute	Description
`features`	Placeholder for any features.
`meta_features`	Placeholder for service analysis.

Creating Splunk integrations

A Splunk integration collects log data and different types of metrics, including live and historical data, and sends it to the gRPC server as Cloud events at specified intervals.

Log data is used to establish a baseline of normal behavior and detect anomalies. Metric data helps to monitor your environment and process alerts. Anomalies can be correlated with alerts, and published to your ChatOps interface, to help you determine the cause and resolution of a problem. Splunk Enterprise v8.1 is the version that is supported for the Splunk integration.

To activate the integration, you must have an endpoint and a user ID and password credentials or a token. You can also configure settings for performance by providing log or metric data parameters. The metric anomaly detection and Log anomaly detection AI algorithms analyze the Splunk data.

For more information about working with Splunk integrations, see the following sections:

- Creating Splunk integrations
- Specifying a custom query for the Splunk host
- Enabling Splunk integrations
- Editing Splunk integrations
- Deleting Splunk integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Creating Splunk integrations

About this task

Before you create a Splunk integration, consider the following details:

- **Load**: To prevent the integration from placing an inordinate load on your data source and potentially impacting your logging operations, the integration connects to only one API with a default data frequency of 60 seconds. This frequency is controlled by the **Sampling rate** setting that is configured when you create the integration.
- **Access**: Custom data sources are cloud-based REST APIs. Access is configured by using the authentication methods that are specified in the **Authentication type** setting when you create the integration.
- **Data volume**: Data volume depends on the application, and is not a set value. Therefore, it does not appear in the settings.

Procedure

To create a Splunk integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Splunk** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section, or alternatively start typing the integration name in the searchbar and the corresponding tile appears.
5. On the side-panel, review the information and when ready to continue, click **Get Started**.
6. On the *Add integration* page, define the general integration details:
   - **Name**: Set a display name for your integration. Use a name that uniquely identifies this integration.
   - **Description (optional)**: Provide a description for the integration.
   - **Splunk service URL**: Enter the URL for your Splunk instance. For example `https://myinstance.mydomain.com:8089`.

     Note: If you have any restrictive EgressNetworkPolicies in place, ensure that they are updated to allow for this integration.
   - **Authentication type**: Select one of the following options:

- **User ID/Password**: The Splunk instance has a user ID and password as authentication. You must enter both in the integration configuration that appears.
- **Token**: The Splunk instance is authenticated with a temporary token field that appears.

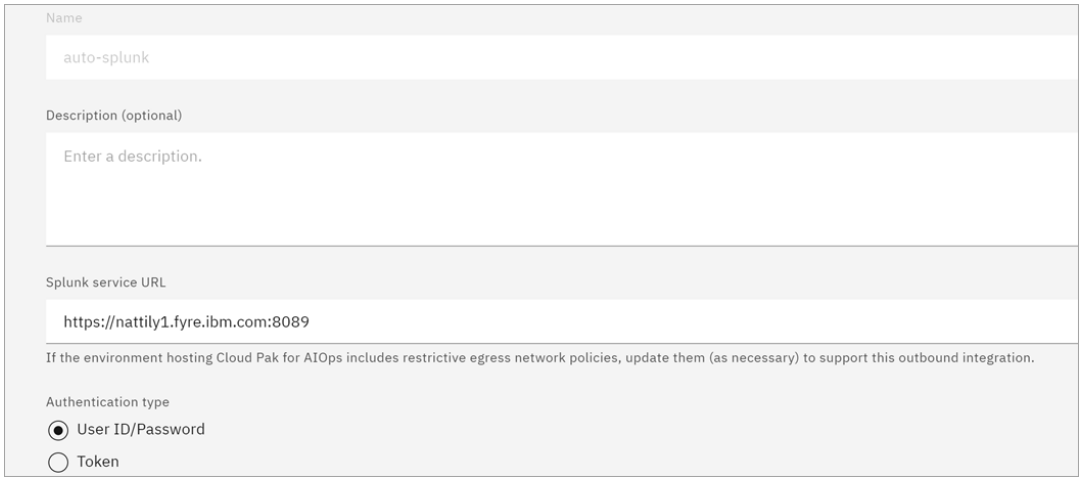

Figure. Create Splunk integration

- **Splunk dashboard URL**: Enter the dashboard URL for your Splunk instance. For example `https://myinstance.mydomain.com:8080`.
- **Certificate (optional)**: Provide a certificate to verify the SSL/TLS connection to the REST service.
- **Deployment options**: Select one of the two options, **Local** or **Remote**. Use **Local** to deploy in the same cluster as IBM Cloud Pak for AIOps console. Select **Remote** to deploy anywhere, such as on a different network region, on SaaS, or on a remote on-premises system (VM, cluster, container).

  Note: Remote deployment only supports metric integration. If you need to use the log integration, you must select **Local**. If you select **Remote**, after adding the integration, you are provided with a bootstrap command to finish the deployment.

7. To verify the SSL/TLS configuration:
   1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
   2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.

Figure. Test connection

8. Click **Test connection** (required). The test can take some time to complete.
9. Click **Next**.
10. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to Splunk via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server. **Note:** The URL for the metrics-only integration should have the protocol in the URL.
    - **Port number of proxy server**: Enter a port. The default is 8080.

Note: Only unauthenticated HTTP proxy is supported.

11. Click **Next**.
12. On the *Collect log data* page, define how you want to collect log data for use in AI training:

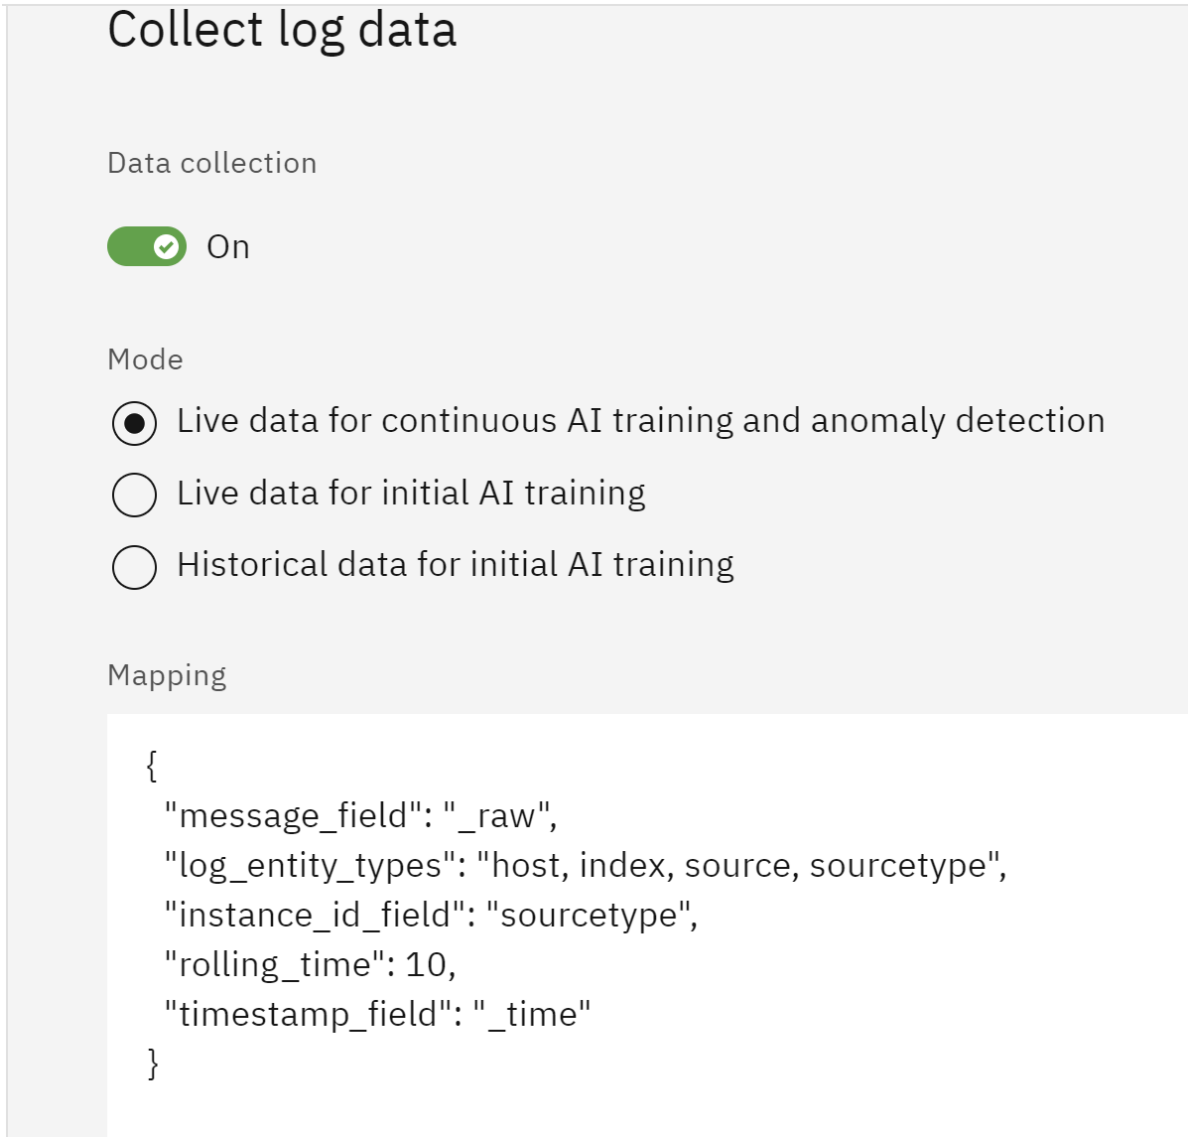

Figure. Collect log data

- **Data collection**: Use the toggle to turn on or off data collection.

- Set the toggle to **Off** (default) if you do not want to collect log data. With this setting, no data is collected through the integration, which results in no anomalies being detected as no AI model is trained. You must turn the toggle to **On** to begin any data flow through the integration.
- Set the toggle to **On** to turn on data collection.

  Note: Log data collection is not supported for a remote deployment. If you want to collect log data, you must deploy a local integration.

- **Mode**: Select how you want data to be collected through the integration for AI training:
  - **Live data for continuous AI training and anomaly detection**: This option enables continuous live data collection through the integration to train AI models and analyze data for anomalous behavior.

    Important: Before you use this option, you must first set **Mode** to **Historical data for initial AI training** and collect a minimum amount of data. Then, you need to run AI training on that data. For more information, see Planning data loading and training.
  - **Live data for initial AI training**: This option collects a single set of training data to define your AI model. Data collection takes place over a specified time period that starts when you create your integration.

    Note: If you select this option, you must disable your integration when you collect enough data for training. If you do not disable the integration, it continues to collect data. For more information about AI model training, including the minimum and ideal data quantities, see Configuring AI training. For more information about disabling and enabling the integration, see Enabling and disabling Splunk integrations.
  - **Historical data for initial AI training**: This option collects a single set of training data to define your AI model. Historical data is harvested from existing logs in your integration over a specified time period in the past. You must specify the start and end dates for this data collection, along with the parallelism of your source data.
    - **Start date**: Select a start date from the calendar. The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.
    - **End date**: Select the end date from the calendar. The recommended time period is two weeks.
    - **Source parallelism (1-50)**: Select a value to specify the number of requests that can run in parallel to collect data from the source. Generally, you can set the value to equal the number of days of datat that you want to collect. When you are setting this value, consider the number of requests that are allowed by the source in a minute. For example, if only 1-2 requests are allowed, set the value to be low.

  Important: Keep in mind the following considerations when you select your data collection type:
  - Anomaly detection for your integration occurs if you select *Live data for continuous AI training and anomaly detection*.
  - Different types of AI models have different requirements to properly train a model. Make sure that your settings satisfy minimum data requirements. For more information about how much data you need to train different AI models, see Configuring AI training.
  - **Mapping**: Enter the field-mapping information.

  You can improve search performance by mapping your implementation fields to the standard IBM Cloud Pak for AIOps fields. For more information about this mapping, including how to clean data for use in IBM Cloud Pak for AIOps, see, Mapping data from incoming sources.

  The following code shows the supported data schema for the integration:

```
{
  "rolling_time": 10,
  "instance_id_field": "sourcetype",
  "log_entity_types": "source",
  "message_field": "_raw",
  "timestamp_field": "_time",
  "resource_id": "sourcetype"
}
```

```
* **Filters (optional)**: Enter source, app, or log-level filters to apply to the event data. For more information, see [Search Tutorial ![Opens in a new tab](../images/icons/launch-glyph.svg "Opens in a new tab")](https://docs.splunk.com/Documentation/Splunk/8.1.0/SearchTutorial/Usethesearchlanguage){: external} in the Splunk documentation.

* **Base parallelism (1-50)**: Select a value to specify the number of Flink jobs that can run in parallel. These jobs run to process and normalize the collected data. The default value is 1. However, it is recommended to use a higher value than 1 so that you can process data in parallel. This value cannot exceed the total available free Flink slots. In a small environment, the available flinks slots are 16, while in a large environment, the maximum available slots are 32. If you are collecting historical data with this integration, you can set this value to be equal to the **source** parallelism.

  **Note:** To improve data throughput, you can increase the base parallelism value incrementally. For more information about maximum base parallelism for starter and production deployments, see [Improving data streaming performance for log anomaly detection](../configuring/improving_data_streaming_performance.html).

* **Sampling rate (1-150 seconds)**: Select a rate at which data is sampled from live sources (in seconds). The default value is `60`.

* **JSON processing option**: Select a JSON processing option from the following options:

    * **None**: The default option. The JSON is not processed or modified.
    * **Flatten**: This option flattens the JSON object by removing the opening and closing braces.
    * **Filter**: This option extracts the JSON object and replaces it with an empty string.

 For more information about the options, see [Managing embedded JSON](../configuring/managing_embedded_json_lad.html).
```

13. Click **Next**.
14. On the *Collect metric data* page, define how you want to collect metric data for monitoring.

- **Enable Data collection**: Set the toggle to on to enable the data collection. If data flow is disabled, a new integration is created, but metrics are not collected.
- **Select an index to see all associated source types**: Pick a splunk index from the list to see its related source types.
- **Select a source type to see all associated metrics**: Choose a source type from the list to see its related metrics in the filter table.
- **Search all metrics for the current selection**: Search through all the metrics that are associated with the specified index and source type and select the wanted metrics from the table.
- **Hosts**: Select the hosts you want to get metric data for. All hosts in Splunk of the specifed source type, that are not marked as `too_small` and that have data from within the last 48 hours, will be listed.
- **Aggregation interval (minutes)**: Enter a value in minutes. The value represents the frequency at which data is collected. The default value is 5 minutes.

Complete the settings to use either historical or live data collection:

- To use only live data collection, complete the following settings:

  Select the checkbox **Only collect live data once the integration is established**.

  Note: If you choose to collect only live data, you cannot collect historical data after live data collection starts.

- To use historical data collection, complete the following settings:
  - Do not select the checkbox **Only collect live data once the integration is established**.
  - Set the **Start date**. Select a start date from the calendar and enter the time in hh:mm (hours and minutes) format. Select the time zone from the dropdown list, for example (Localtime or UTC).

    Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.
  - (Optional) Set an *end date* for the data collection. If you do not specify the end date, then live data collection follows the historical data collection. If you do not want to set an end date, click **Remove end date**.

    To add the end date, click **Add end date**. For the **End date**, select an end date from the calendar and enter the time in hh:mm format. The end date uses the same time zone as the start date.

15. Click **Next**.
16. The UI displays the *Resource requirements* page.

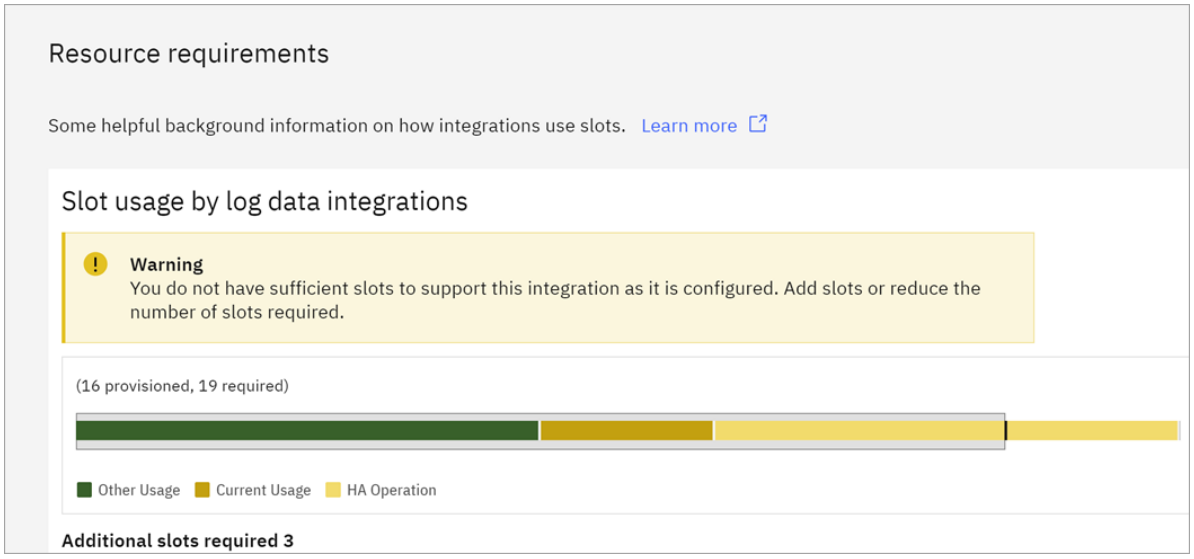

Figure. Resource requirements

Note: If logs data collection is set to **Off** and metrics data collection is set to **On**, you can skip this page.

On the *Resource requirements* page, you can review the slot usage for your log integrations to see if there are enough slots to fully support the integration for multizone high availability.

If you set the **Data collection** toggle to **On**, you will see the resource management overview.

- If your current usage and other usage are less than the provisioned slots, but the high availability slots exceed the provisioned slots, you will be able to create the integration, but will see a warning that you do not have enough slots. The integration will not have multizone high availability.
- If your projected usage exceeds the provisioned slots, you will not be able to create the integration because you do not have enough slots on your system for log data integrations.
- If your total slots, including high availability slots, are within the provisioned slots, the integration will have multizone high availability.

Note: High availability operation assumes high availability for three zones.

If you set the **Data collection** toggle to **Off**, you will see a message stating that you need to enable logs data collection to see the resource management overview. no slots are used by that integration.

17. Click **Done**. You created a Splunk integration in your instance.

After you create your integration, enable data collection to use your integration with the AI of IBM Cloud Pak for AIOps. For more information, see Enabling and disabling data collection.

For more information about performance considerations for metric data collection, see Performance considerations for metric data collection.

To create more integrations (such as a ChatOps integration), see Configuring Integrations.

For more information about working with the insights provided by your integrations, see ChatOps insight management.

Specifying a custom query for the Splunk metrics hosts

If the Splunk hosts are not showing up in the UI, you can specify a custom query. The expected output of the query is a column named **host** which has all the unique hosts for the Splunk system. You should keep performance in mind with a custom host query. Ideally the query should execute in less than 10 seconds. There is a restriction that the custom query must take less than 30 seconds.

Important: If the Splunk hosts are showing up in the UI when using the default host query, there is no need to use a custom host query.

To specify a custom query, use the following steps:

1. Update the configmap from default **SPLUNK_HOST_QUERY** to customize the query: **oc edit configmap aimanager-aio-controller-config**

   Default configmap:

   ```
   data:
     SPLUNK_HOST_QUERY: default
   ```

   Example updated configmap:

   ```
   data:
     SPLUNK_HOST_QUERY: >-
       search index=main sourcetype!=*too_small* earliest=-48h@h | stats count by
       host
   ```

2. Check that the configmap is updated correctly: **oc describe configmap aimanager-aio-controller-config**

   ```
   Data
   ====
   SPLUNK_HOST_QUERY:
   ----
   search index=main sourcetype!=*too_small* earliest=-48h@h | stats count by host
   ```

3. Bring down the controller deployment to 0 and then back up to 1 again.

   ```
   % oc scale deployment aimanager-aio-controller --replicas=0
   % oc get deployment |grep controller
   aimanager-aio-controller                          0/0     0            0           4d10h
   % oc scale deployment aimanager-aio-controller --replicas=1
   % oc rollout status deployment/aimanager-aio-controller
   Waiting for deployment "aimanager-aio-controller" rollout to finish: 0 of 1 updated replicas are available...
   deployment "aimanager-aio-controller" successfully rolled out
   % oc get deployment |grep controller
   aimanager-aio-controller                                  1/1     1            1           7d3h
   ```

4. Check that the env variable is updated in the controller pod:

   ```
   % oc rsh "$(oc get pod |grep aio-controller |awk '{print $1}')" /bin/bash -c 'echo $SPLUNK_HOST_QUERY'
   SPLUNK_HOST_QUERY=search index=main sourcetype!=*too_small* earliest=-48h@h | stats count by host
   ```

Enabling and disabling Splunk integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. If you selected *Live data for initial AI training* when you created your integration, you must disable the integration before AI model training. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Splunk** integration type.
4. Click the integration that you want to enable or disable.
5. Go to the *AI training and log data* section, and set **Data collection** to **On** or **Off** to enable or disable log data collection.

   Note: Log collection is only supported in local deployment mode. If you need to use the log integration, you must set the deployment option to **Local**.

6. Go to the *Collect metric data* section, and set **Enable Data collection** to on or off to enable or disable metric data collection.

Note: Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting Splunk integrations.

Editing Splunk integrations

After you create your integration, your can edit the integration. For example, if you specified *Historical data for initial AI training* but now want your integration to pull in live data for continuous monitoring, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Splunk** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Splunk integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration. Click **Next** to go through the integration configurationn pages. Click **Save** when you are done editing.

Your integration is now edited. If your application was not previously enabled or disabled, you can enable or disable the integration directly from the interface. For more information about enabling and disabling your integration, see Enabling and disabling Splunk integrations. For more information about deleting a integration, see Deleting Splunk integrations.

Deleting Splunk integrations

If you no longer need your Splunk integration and want to not only disable it, but delete it entirely, you can delete the integration from the console.

Note: You must disable log data collection before you delete your integration. For more information about disabling data collection, see Enabling and disabling Splunk integrations.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Splunk** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Splunk integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Creating Zabbix integrations

A Zabbix integration collects different types of metrics, including live and historical data, to monitor and analyze application performance. It gathers metrics at scheduled intervals from the Zabbix server, and sends data to the gRPC server as cloud events. IBM Cloud Pak for AIOps uses this metric data to identify deviations from the normal behavior and report anomalies. The AI algorithm that analyzes Zabbix data is Metric anomaly detection.

For more information about the Zabbix integrations, see the following sections:

- Before you begin
- Creating Zabbix integrations
- Enabling and disabling Zabbix integrations
- Editing Zabbix integrations
- Deleting Zabbix integrations

For more information about HTTP headers for the various credential types, see HTTP headers for credential types.

Before you begin

Before you create a Zabbix integration, complete the following steps:

- Install Zabbix v6.0
- Add and configure hosts in the Zabbix server

Note: The Zabbix integration does not support the Zabbix server 6.4 version (or newer).

For more information about installing Zabbix and setting up host, see the Installation and the Quickstart sections in the Zabbix documentation.

To create a Zabbix integration, you must have the following information:

- Endpoint
- Username and Password or API Token

Creating Zabbix integrations

To create a Zabbix integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Integrations* page, click **Add integration**.
4. From the list of available integrations, find and click the **Zabbix** tile.

   Note: If you do not immediately see the integration that you want to create, you can filter the tiles by type of integration. Click the type of integration that you want in the *Category* section, or alternatively start typing the integration name in the searchbar and the corresponding tile appears.
5. On the side-panel, review the instructions and select your required options from the following sections:
   - **Select the data types that you need to collect**: Select the relevant checkbox for *Metrics*, or *Topology*. You can select either Metrics or Topology but not both at the same time.
   - **Specify where you'd like to install the integration**: Select between the *Cluster running Cloud Pak for AIOps* or *Self-hosted with network visibility to Zabbix* radio buttons.
   - **Select Cloud Pak for AIOps integration**: You can leave this at the default *Use the integration recommended by Cloud Pak for AIOps*, or change it to just *Metrics*, or *Topology*.

     The below steps presuppose you select *Metrics* but if you do select *Topology* then you will be brought to a *New observer job* page. The Zabbix observer will read data from a Zabbix instance through its REST APIs and load a topology into Cloud Pak for AIOps. For more information, see Configuring a Zabbix observer job.
6. Click **Next**.

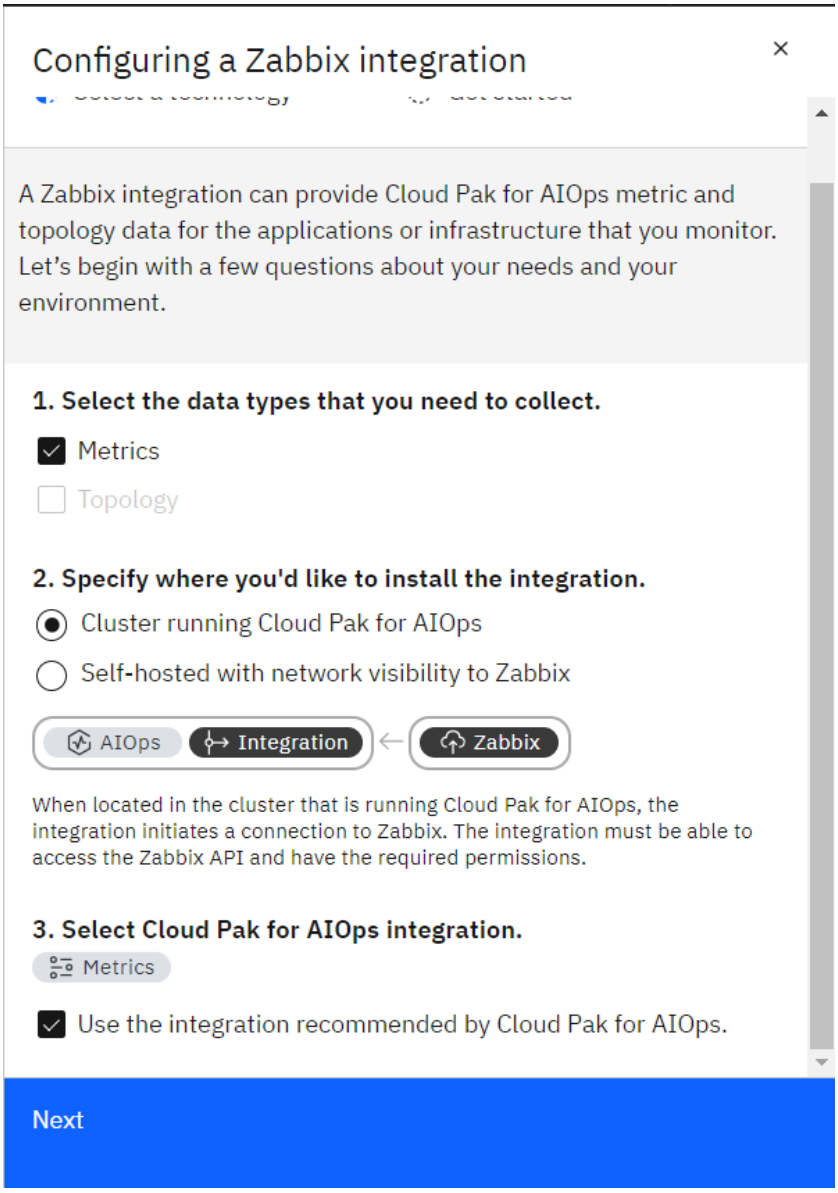

Figure. Configure Zabbix integration

7. On the side-panel, review the information and when ready to continue, click **Get Started**.

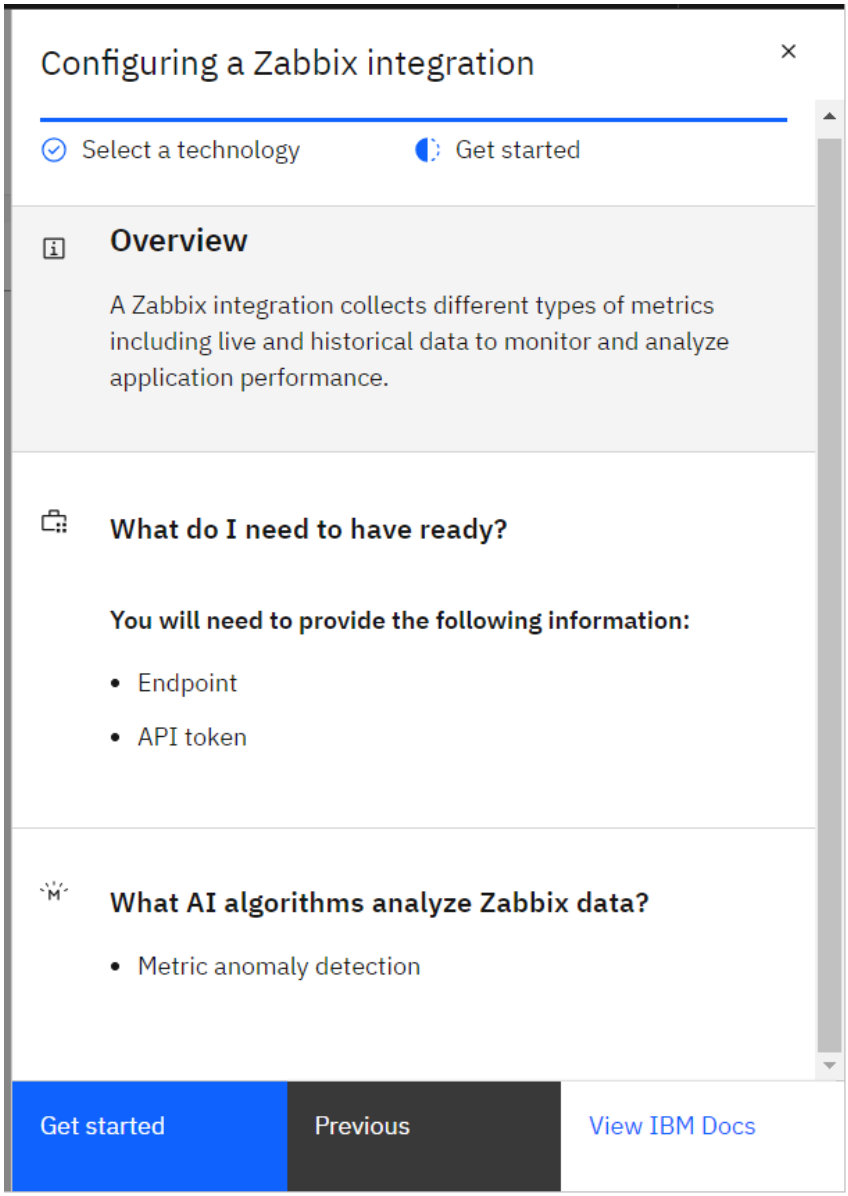

Figure. Get started

8. On the *Add integration* page, define the general integration details:

- **Name**: Create a unique name for your integration.

  Note: Currently, the integration name field only supports alphanumeric characters and excludes spaces and other special characters.

- **Description (optional)**: Provide a description for your integration.
- **Endpoint**: Both http and https urls will be supported by the endpoint (for example, http://<Zabbix-server-hostname>/zabbix/api_jsonrpc.php or https://<Zabbix-server-hostname>/api_jsonrpc.php). In this case you can enter the following endpoint for your integration:

  `<protocol>://<Zabbix-server-hostname>/zabbix/api_jsonrpc.php`

  where **`protocol`** is HTTP or HTTPS and **`zabbix`** is the path to **`api_jsonrpc.php`** file, which is located in the front-end directory.

- **Authentication type**: Select between **Username/Password** or **API Token**.
  - **Username**: Enter a username for the Zabbix integration.
  - **Password**: Enter a password for the Zabbix integration.
  - **API Token**: Enter an API token for the integration.

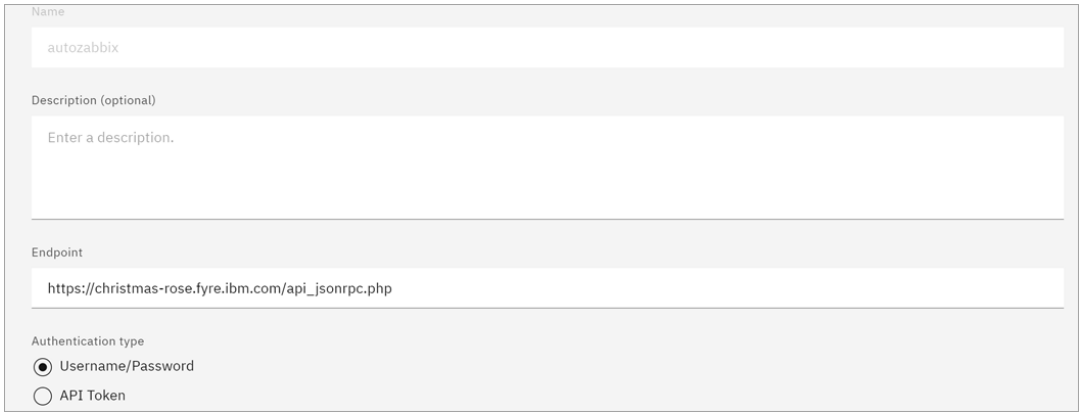

Figure. Create Zabbix integration

Support for Zabbix v5.x

There is a known limitation whereby the **Username/Password** authentication does not work for Zabbix v5.x. You must use the **API Token** authentication method instead.

The following sample steps show how to retrieve the API authentication token **$auth** from the Zabbix server. Ensure that the auto-logout option is not selected for the Zabbix user.

```
% url=http://zabbixserverv5.com/zabbix/api_jsonrpc.php
% auth=$(curl -s -X POST -H 'Content-Type: application/json-rpc' \
-d '
{"jsonrpc":"2.0","method":"user.login","params":
{"user":"myApiUser","password":"myApiPassword"}
,
"id":1,"auth":null}
' $url | \
jq -r .result
)
% echo $auth
3398cacccfa6e8xxx
```

Note: For this example, you must have **curl** and **jq** installed.

For more information see Zabbix documentation.

9. To verify the SSL/TLS configuration:
    1. Set the **Verify the SSL/TLS certificate for the REST service** toggle to *on*.
    2. Either enter a CA certificate used to verify the SSL/TLS integration to the REST service or click **Fetch SSL certificate** to fetch the certificate automatically.
10. Click **Test connection**.

    Note: After you click **Test connection**, wait for the test to succeed before you continue to the next step. It might take some time. If the test fails, verify your credentials, and ensure that the server is up and running. However, you can still move to the metric selection page.

- **Deployment options**: Select one of the options, **Local** or **Remote**.
    - **Local**: This option deploys the integration in the same cluster where IBM Cloud Pak for AIOps is installed.
    - **Remote**: This option deploys it in your chosen location. After you add the integration, you get a bootstrap command to finish the deployment.

Figure. Test connection

11. Click **Next**.
12. On the *Configure Proxy* (Optional) page complete the following fields:
    - **Connect to Zabbix via a proxy server**: Set the toggle button to *on*.
    - **URL of HTTP proxy server**: Enter a URL for the HTTP proxy server.
    - **Port number of proxy server**: Enter a port. The default is 8080.

Note: Only unauthenticated HTTP proxy is supported.

13. Click **Next**.
14. Enter *Collect metric data* information:

- **Enable data collection**: Toggle the switch to the on position. However, if you disable data flow, a new integration is created, but metrics are not collected.
- **Select templates**: You can either select all templates or choose the templates that you want to apply to the hosts. Only templates that have metrics will be shown in the UI.
    - To select all templates, click **Select all templates**.
    - To clear all selection, click **Unselect all templates**.
    - To choose the required templates, select the checkbox of the templates you require from the drop-down list.

  Note: You must select templates appropriate to the hosts. This is because if an item from the template is not available for the host, the integration cannot pull data for that item.

  For more information about performance considerations for metric data collection, see Performance considerations for metric data collection.
- **Search and select the required metrics**: After the templates are loaded, the filter table displays all the associated built-in metrics of the selected templates. These metrics are preselected. You can search through and change the selection, if required.
    - To select a metric, click the checkbox of the required metric.
    - To remove a selected metric, clear its corresponding checkbox.
    - To select or clear all selected metrics, click **Built-in metrics name**. Alternatively, you can click **Select all** or **Unselect all** on the filter table header.
    - To change the size of the page that lists the built-metrics, select a number from the **Items per page** list at the end of the table.
    - To navigate through the pages to see all the metrics, click the next page or previous page arrows.

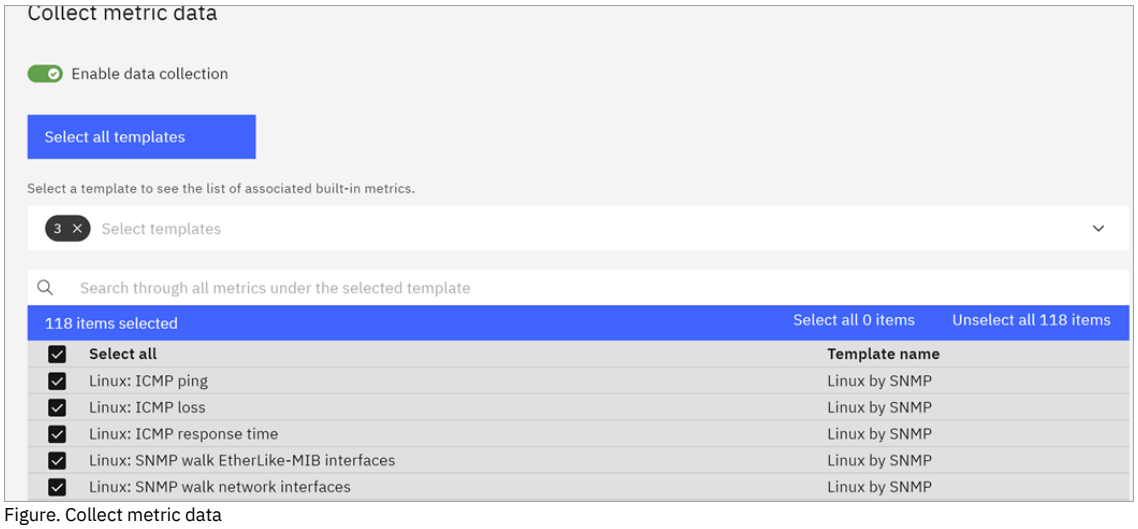

Figure. Collect metric data

- **Hosts**: The hosts are preselected on the load itself. To undo the selection, clear the checkbox of the hostname from the drop-down list.

  Note: If any of the hosts are not available, a notification is displayed. Unselect the hosts that are not available or ensure that all hosts are working in the Zabbix target system before you create your Zabbix integration. If a host goes down after you create the integration, edit and remove the host in your integration.

  Note: Zabbix organizes hosts based on their IP address. Therefore, if two hosts have the same IP address, then selecting one of these hosts results in both hosts getting selected.
- **Base parallelism**: Specify the number of requests that can run in parallel. The default value is 3.

- **History Span (minute)**: Enter a value in minutes. The value represents the time interval for live or historical data collection. The default value is 1.

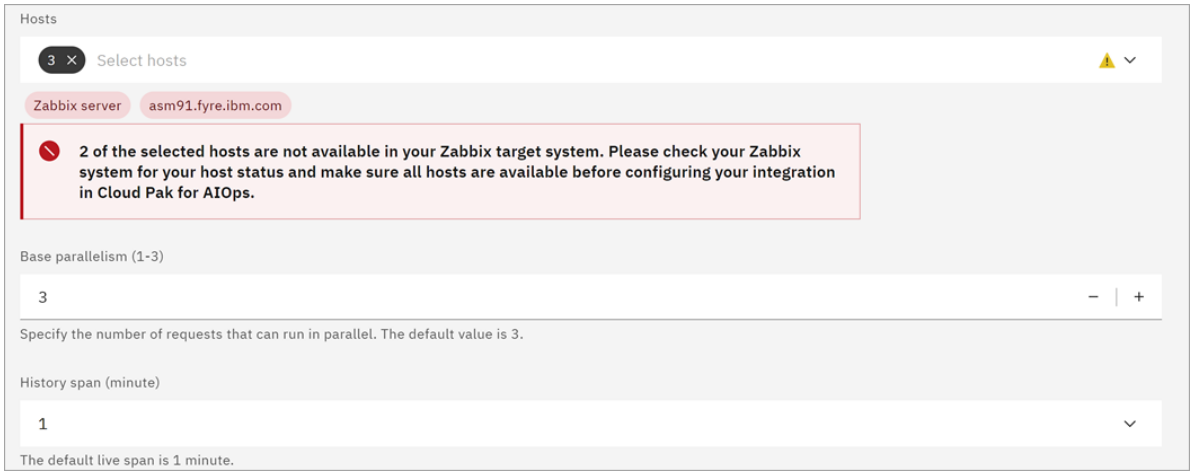

Figure. Create Zabbix integration hosts

- *Select historical or live data collection*:

  Note: If you choose to collect only live data, you cannot collect historical data after the live data collection starts.

- **Live data collection**: To collect live data, complete the following steps: * **Only collect live data once the integration is established**: Select the checkbox. * **Integration interval in minutes for live metrics (1-60)**: Enter a value in minutes. The value represents the frequency at which data is sampled for live metrics. The default value is 5.

- **Historical data collection**: If you do not select live data collection, then historical data metrics are automatically collected. To collect historical data, complete the following steps:

  - **Start date and time**: Select the start date from the calendar and enter the time in the *hh:mm* format (hours and minutes).

  Note: The start date must not exceed 31 days from the present as the maximum time period for historical data collection is 31 days. The recommended time period is two weeks.

  - **Time zone**: Select your time zone from the drop-down list.
  - **End date and time**: Click **Add end date** and select a date from the calendar. Also, enter the time in the *hh:mm* format (hours and minutes). If you want to remove an end date, click **Remove end date**.

    Note: If you do not set an end date, IBM Cloud Pak for AIOps collects historical data from the specified start date and continues with live data collection. Therefore, you must specify the integration interval for live metrics.
  - **Integration interval in minutes for live metrics (1-60)**: Enter a value in minutes. The value depicts the frequency at which data is sampled for live metrics. The default value is 5.

15. Click **Done**.

You created a Zabbix integration in your instance.

Enabling and disabling Zabbix integrations

If you didn't enable your data collection during creation, you can enable your integration afterward. You can also disable a previously enabled integration the same way. To enable or disable a created integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. On the *Manage integrations* tab of the *Integrations* page, click the **Zabbix** integration type.
4. Click the integration that you want to enable or disable.
5. Set **Enable data collection** to **On** or **Off** to enable or disable log data collection. Disabling data collection for an integration does not delete the integration.

You enabled or disabled your integration. For more information about deleting a integration, see Deleting Zabbix integrations.

Editing Zabbix integrations

After you create your integration, your can edit the integration. For example, if you want to change the time interval of how often your job runs, you can edit it. To edit a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Zabbix** integration type on the *Manage integrations* tab of the *Integrations* page.

4. On the Zabbix integrations page, click the name of the integration that you want to edit. Alternatively, you can click the options menu (three vertical dots) for the integration and click **Edit**. The integration configuration opens.
5. Edit your integration. Click **Next** to go through the integration configuration pages. Click **Save** when you are done editing.

You edited your integration.

Deleting Zabbix integrations

If you no longer need your zabbix integration and want to delete it entirely, you can delete the integration from the console.

To delete a integration, complete the following steps:

1. Log in to IBM Cloud Pak for AIOps console.
2. Expand the navigation menu (four horizontal bars), then click **Define** > **Integrations**.
3. Click the **Zabbix** integration type on the *Manage integrations* tab of the *Integrations* page.
4. On the Zabbix integrations page, click the options menu (three vertical dots) for the integration that you want to delete and click **Delete**.
5. Enter the name of the integration to confirm that you want to delete your integration. Then, click **Delete**.

Your integration is deleted.

Delay configuration in data integrations

In live data mode the integration might need a delay to offset the query time windows to provide a time buffer and prevent retrieving partial real-time data.

The following table lists the environment variables for various integrations:

Integration environment variables

Integration	Environment variable for Delay
Custom	CUSTOM_QUERY_DELAY
ELK	ELK_QUERY_DELAY
Falcon LogScale	HUMIO_QUERY_DELAY
Mezmo	MEZMO_QUERY_DELAY
PagerDuty	PAGERDUTY_QUERY_DELAY
Splunk	SPLUNK_QUERY_DELAY

To add delay settings in the Flink, open the configuration by using the following commands:

- For PagerDuty:

  ```
  oc edit flinkdeployment aiops-lad-flink
  ```

- For Falcon LogScale, Custom, Mezmo, ELK, and Splunk:

  ```
  oc edit deployment aimanager-aio-controller
  ```

  In the configuration, edit the `env` section.

  For example, set a 60-seconds delay for Splunk integration:

  ```
  env:
   - name: SPLUNK_QUERY_DELAY
     value: "60"
  ```

Note:

- The values that are set in the configuration must be in seconds.
- For existing integrations to pick up delay values, you must save the integrations again.
- Delays are not applicable to historical mode integrations.

Mapping data from incoming sources

With any integration, you can specify your own mappings to the standard IBM Cloud Pak for AIOps values to optimize search performance for any data type.

For each type of integration, you can edit which fields map to the standard values. By default, each integration type (including custom integrations) uses a default field mapping based on what the source data typically looks like. When you map source fields, you're replacing or supplementing those values with something else in your logs.

Mapping data types

- Mapping log data

- Mapping event data (Only available through a Kafka integration)
- Mapping similar ticket data from ServiceNow

Cleaning mapped data by using regular expressions

While you can use the *Field mapping* section of the integration page to customize field mappings to data values, you can also clean incoming data from your integration here. You can use regular expressions in the mapping field to strip formatting if you know that your data comes formatted in a specific way that affects training. For example, if your log files are always prefixed by the date and time, your training includes that prefix. As a result, IBM Cloud Pak for AIOps flags items that are also prefixed with the same timestamp. The following example illustrates how you can use the *Field mapping* section to clean your message prefixes.

Note: Using regular expressions in the *Field mapping* section is not limited to the following example. You can affect change on any mapped field in the same manner.

In this example, your Mezmo output produces the following timestamp at the beginning of every log entry:

```
Mar  9 03:30:01 TRACE [Controller id=2] Leader imbalance ratio for broker 2 is 0.0 (kafka.controller.KafkaController)
```

You can add `custom_regex` immediately following the mapping that you want to affect to exclude entries that match your proposed regular expression. In this example, you want to exclude timestamps that look like `Mar 9 03:30:01`. You can write a regular expression that follows the formatting of "MMM D HH:MM:SS" to ignore the month value to ensure that your training applies to all months. The following regular expression excludes the timestamp in the example log:

```
^[A-Z][a-z][a-z]\s+([1-9]|[1-2][0-9]|3[0-1])\s+[0-9][0-9]:[0-9][0-9]:[0-9][0-9]\s
```

Note: You can use AND (`&`) and OR operators (`|`) in combination with regular expressions to exclude more patterns. You can implement these operators in the *Field mapping* section by including the following content:

```
{
  "codec": "mezmo",
  "message_field": "message",
  "custom_regex": [
    "^[A-Z][a-z][a-z]\\s+([1-9]|[1-2][0-9]|3[0-1])\\s+[0-9][0-9]:[0-9][0-9]:[0-9][0-9]\\s"
  ],
  "log_entity_types": "container",
  "instance_id_field": "_app",
  "timestamp_field": "_ts"
}
```

Important: If you previously trained your AI models with a different mapping, you must delete and retrain your models with the new mapping in place. For more information about altering models, see Configuring AI models.

Mapping log data from incoming sources

With any integration, you can specify your own mappings to the standard IBM Cloud Pak for AIOps values to optimize search performance for any data type.

For each type of integration (Custom, ELK, Falcon LogScale, Kafka, Mezmo, and Splunk), you can edit which fields map to the standard values. By default, each integration type (including custom integrations) uses a default field mapping based on what the source data typically looks like. When you map source fields, you're replacing or supplementing those values with something else in your logs.

Mapping log anomaly data

The Log Anomaly service detects abnormal activities from system logs, which help Site Reliability Engineers (SREs) to better react to issues. Two types of anomalies are considered: *quantitative anomalies* (where constant linear or quantitative relationships are broken) and *sequential anomalies* (where a log sequence deviates from normal patterns of program flows).

IBM Cloud Pak for AIOps ingests logs from standard or custom data sources. Raw logs from supported standard data sources are transformed to a normalized format, as shown in the following example. Data from custom data sources must be transformed into normalized format first to be used in an integration (or eventually for AI model training).

Log anomaly raw data

To maintain the structure of the log anomaly data in the Elastic database, you must transform raw log anomaly data into a normalized format. The following examples illustrate raw JSON log anomaly data that comes from the ELK Stack, Falcon LogScale, and Splunk:

ELK Stack raw data example

Normalized log data example

The following sample illustrates the result of mapping data from an external log source for use with IBM Cloud Pak for AIOps:

```
{
    "timestamp": 1655991641000,
    "instance_id": "calico-node-jn2d2",
    "application_group_id": "1000",
    "application_id": "1000",
    "features": [],
    "meta_features": [],
    "message": "[64] ipsets.go 254: Resyncing ipsets with dataplane. family=\"inet\"",
    "entities": {
        "pod": "calico-node-jn2d2",
        "cluster": null,
        "container": "calico-node",
        "node": "kube-bmgcm5td0stjujtqv8m0-ai4itsimula-wp16cpu-00002c34"
    },
    "type": "StandardLog"
}
```

Log anomaly normalized attributes

Required attributes expected as input for the pipeline

Attribute	Description
`timestamp`	Epoch Timestamp of the event in the log entry. The epoch time should be in milliseconds (13 digit) and not in seconds (10 digit).
`utc_timestamp`	The `utc_timestamp` of the event in the log entry. The format should be in `yyyy-MM-dd HH:mm:ss.SSS` format. The value of this field should be equivalent for the epoch value of the `timestamp` field.
`instance_id`	Logs can be trained based on certain attributes, like the application to which the log entry belongs, the hosts from which the log is generated, or the pods from which the log is generated. `instance_id` is the value of the attribute that is chosen to be the key upon which the models are built. Attributes chosen to be `instance_id` are specified in the ingest configuration during onboarding.
`application_id`	Application from which the log entry was generated. It can be the same as `instance_id` if the `instance_id` is chosen to be the application
`features`	Contains log templates
`message`	Log message for the log entry. It can be an error message, a normal information message, or a debug message. A good combination of message types yields the best results. For example, if the logs are only error messages or if no error messages appear in the logs, the quality of the anomaly detection suffers.
`entities`	Entities are provided for better event attribution. They provide clues to connect information from multiple data sources such as events, logs, and incidents, and also are used to globalize faulty components. Entities can be infrastructure-related attributes like node name, hostname, IP address, pod name, container name, or cluster name. These attributes are specified as a comma-separated list in the configuration during onboarding. The `entities` attribute must, at least, contain an empty field: `"entities": {}`.

Static attributes

Attribute	Description
`application`	Application that the IBM Cloud Pak for AIOps instance is monitoring. Provided as part of the initial configuration during onboarding
`application_group_id`	Supports multi-tenancy. Provided as part of the initial configuration during onboarding
`type`	Hardcoded to the log

Attributes analyzed and populated in the pipeline

Attribute	Description

Attribute	Description
`meta_features`	Contains windowing details

Examples

Review the following examples to view how to map log data.

Example: Falcon Logscale field mapping

- `message_field` maps to `@rawstring`
- `log_entity_types` maps to `kubernetes.container_name`
- `instance_id_field` maps to `kubernetes.container_name`
- `timestamp_field` maps to `@timestamp`

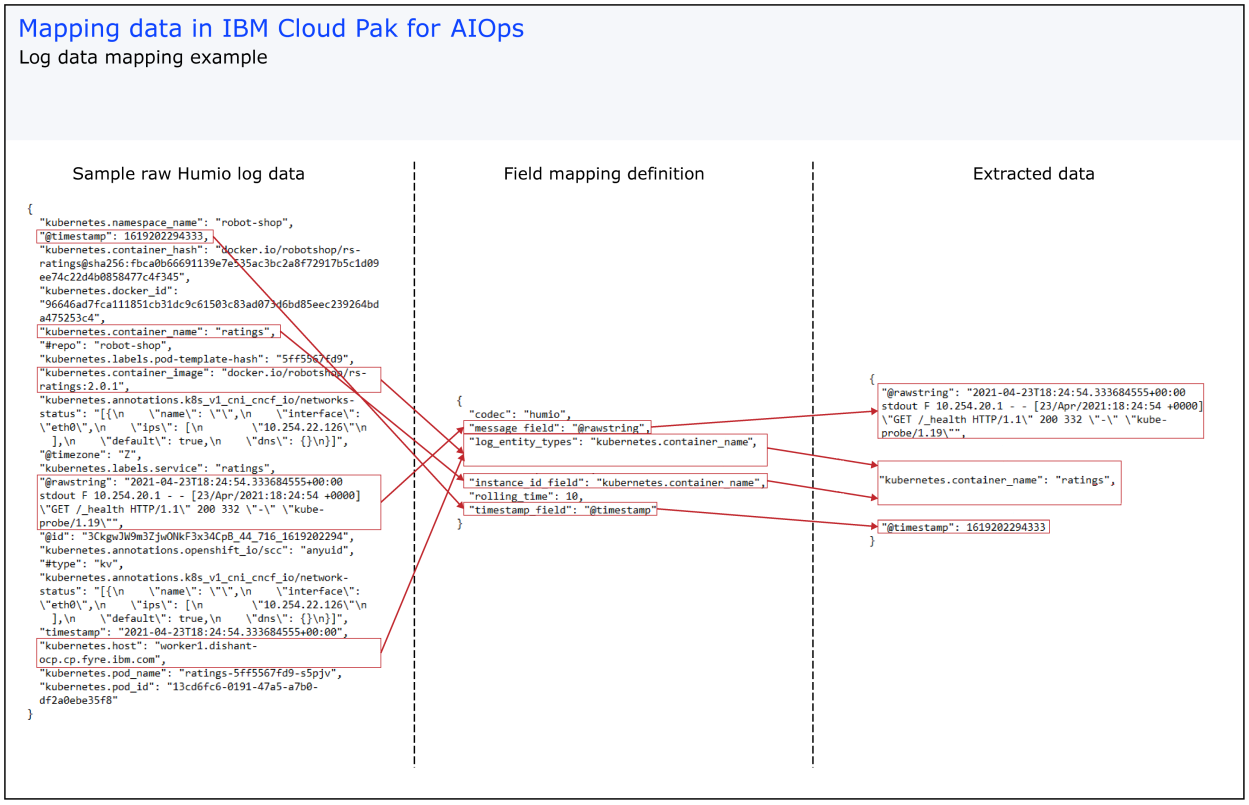

Figure. Falcon Logscale mapping example

All of the values in this Falcon LogScale field mapping correspond to entries in the Falcon LogScale raw data. In this example, the following values map to one another in the Falcon LogScale raw log.

Important: You must specify the corresponding codec in your field mapping when you create your integration. If you do not, the mapping fails. In the preceding example, the mapping specifies `humio` as the codec value.

You can define mappings when you create your integration. The basic building blocks of mappings are similar for most integration types. For logs, the `codec`, `rolling_time`, `instance_id_field`, `log_entity_types`, `message_field`, and `resource_id` mappings typically correspond to values that you might find in your log data. The following table describes typical mapping fields for logs:

Typical mapping values for log integrations

Field Name	Description
`codec`	The type of integration for your incoming data. You must specify the codec value for non-log integrations too. For example, you must specify `humio` for a Falcon Logscale integration mapping, or `servicenow` for a ServiceNow integration.
`rolling_time`	The recurring time interval to capture data from in seconds. The default value is 10 seconds.
`instance_id_field`	The field name in the incoming data that contains the application name. This value is used to identify where your log data is coming from. If you choose an overly specific value, it might lead to flooding the pipeline with irrelevant log data. Ideal candidates for mapping this field include: `kubernetes.namespace_name`, `kubernetes.host`, or `kubernetes.container_name`.
`log_entity_types`	The field name in the incoming data that contains the entity to extract and analyze. The value provides information about the app or service where the log data comes from. Ideal candidates for mapping this field include: `kubernetes.namespace_name`, `kubernetes.host`, or `kubernetes.container_name`.
`message_field`	The field name in the incoming data that contains the log message. For example, `@rawstring`.
`resource_id`	The field name in the incoming data, which contains the specific component that produces the log message. For example, if you deploy your application through a Kubernetes deployment with four replicas, then the `resource_id` field name contains the specific pod name that produces the log message. This information helps to narrow down the component that must be analysed on detection of an anomaly in your application.

Important: Be mindful when you select mapping values for your **instance_id_field** and **log_entity_types** fields. **instance_id_field** identifies the app or service where your messages come from. **instance_id_field** acts almost like the application name in that respect. **log_entity_types** provides information about the app or service, like the name of the pod, the image used in the pod, the node of the pod, and more. If you chose values that are too specific, you might gather too much information from irrelevant pods or projects (namespaces).

Example: Log anomaly output schema

```
{
    "application_group_id": "1",
    "application_id": "1",
    "timestamp":1655991641000,
    "utc_timestamp":"2022-06-23 13:40:41.000"
    "type": "log-anomaly-detection",
    "alert": {

Mapping event data for a Kafka integration

With a Kafka integration, you can gather data for both logs and events. If you are gathering event data, you can specify your own mappings to the standard IBM Cloud Pak for AIOps values.

By default, the Kafka integration uses a default field mapping based on what the source data typically looks like. When you map source fields, you're replacing or supplementing those values with something else in your logs.

Important: Values mapped to the `alert.type.classification` field in the Cloud Pak for AIOps data model are especially significant. Inappropriate values assigned to this field at the time of mapping has a negative impact on several downstream activities, such as Golden Signal classification, incident creation, and recommended policies. Classification should contain information summarizing the event type, for example, CPU Utilization, Node Down, or the actual metric name itself. The following example mappings are from an attribute in an Instana event payload:

```
classification = "Garbage Collection Activity High"
or
classification = "Abnormally High backend commit duration"
or
classification = "Container Memory Usage is getting closer to limit"
```

Sample mappings are available when setting up a generic webhook integration in Cloud Pak for AIOps. Click **Load sample mapping** on the *Configure event mapping* screen and select from the available use cases.

Mapping event grouping data

Event grouping receives streams of events from a Kafka integration, and continuously groups events in real time. This grouping process uses various techniques such as deduplication, temporal clustering, and more. The event grouping service interacts with other services to further provide localization, average severity, pattern recognition, diagnosis, and explanation.

The event grouping service takes normalized data through the integration from an event data source, such as PagerDuty. That data is then used to fit into a single structure that the event grouping service uses to derive new information, such as a topology. Event grouping aims to suppress the number of events to help you diagnose problems with relevant events. This grouping increases the efficiency of handling incidents, and associates the event with other information (such as logs or metrics).

Event raw data
